The Wrist.—For flexion: Flex the supinated forearm on the arm at a right angle. Secure the initial extremity of the rubber bandage by several unstretched turns transversely around the hand; carry the stretched bandage over the flexor surface of the forearm to the lower end of the arm and make a single unstretched turn around the arm just above the elbow. Return with the stretched bandage over the flexor surface of the arm to the hand, and repeat the application between the hand and the arm several times.

For extension: Flex the pronated forearm on the arm at a right angle. The stretched bandage is carried over the extensor surface of the forearm; otherwise the application is the same as for flexion (Fig. 4).

For Finger and Thumb Joints.—For flexion: Completely cover and include the hand in a rubber bandage, the applications over the dorsum of the hand being made with unstretched bandage, and those over flexor surface or palmar surface being made with stretched bandage, securing by unstretched turns around the wrist. This may be combined with bandages for mobilization of the wrist-joint as described above.

For extension: Apply the stretched rubber bandage around the fingers and around the projecting extremity of a suitable posterior splint.

These hand bandages may be applied in Dupuytren's contraction, after operative extirpation of the contracted cirrhotic palmar fascia, and should also be instituted as early as possible after cases of suppurative tenosynovitis to prevent and break up the adhesions between the tendons and tendon sheaths.

The Knee-Joint.—For flexion: A strong chair of a height such that the feet of the seated patient hang free of the floor is necessary. These conditions can be met by the ordinary chair for an adult being placed on and at the edge of a firm table, box or platform. The patient is seated in the chair and secured by a broad bandage carried around the patient's body and back of the chair. A surcingle supplies the purpose very well. Fix the initial extremity of the rubber roller by several unstretched circular turns around the leg just above the ankle; carry the stretched bandage to and around the lower end of the corresponding leg of the chair, and back again to the starting place. Repeat the applications with stretched bandage several times (Fig. 5).

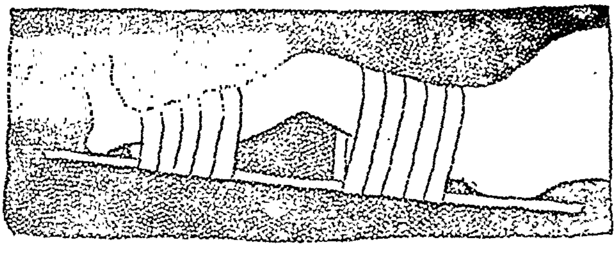

Fig. 6.—Extension of the knee-joint. With the limb on a long posterior splint held by loose gauze bandages, the rubber bandage is made to enclose the knee-joint and the splint, thus producing traction.

For extension: The method by pulley and weight is usually superior to the application of rubber bandage with a posterior splint, and is always to be used in cases of extreme contraction. When the flexion is slight and approximates the complete extension, the rubber bandage method is of value. Application: With the limb on a long strong posterior splint held by loose gauze bandage, place the initial extremity of the rubber roller at the lower end of the thigh just above the knee-joint, and fix by making one or two circular turns over the thigh, and around and including the posterior splint. Repeat the turns a half dozen times with the rubber bandage on the stretch. Repeat the same rubber bandage at the upper end of the leg just below the knee (Fig. 6).

I wish to give full credit to Momburg of the Bier Clinic, Berlin, for originating the idea of making use of the rubber bandage in the mobilization of joints.

THE CONTROL OF PASTEURIZATION[*]

GOTTFRIED KOEHLER, M.D.
Assistant Commissioner of Health

AND

F. O. TONNEY, A.B., M.D.
Director of Municipal Laboratory

CHICAGO

The proper control of milk pasteurization is highly important at the present time—not only to the sanitarian and the public, but also to the conscientious milk-dealer.

Pasteurization as commonly practiced is the heating of milk to a temperature varying from 140 to 185 F. for varying periods of time. This heating may or may not effect the results intended, and the product consequently may or may not be free from the constituents which are intended to be removed or destroyed by the process.

Pasteurization has been lauded and condemned. The misunderstandings are based on the different meanings of the term with reference to the amount of heat applied, the time of exposure and the results accomplished. Practically, pasteurization is resorted to for two reasons: first, and very extensively, to enhance the keeping qualities of the milk. This is accomplished by destroying or materially reducing the number of acid-producing bacteria. Inasmuch as this kind of pasteurization is for commercial purposes the lowest temperature which will serve to accomplish the desired result is employed. Milk treated in this way is not usually rendered safe from a sanitary standpoint, but is nevertheless, often advertised and tendered to the public as germ-free and safe milk. The conception of pasteurization held by some men is that the process described above is intended when pasteurization is recommended as a means of procuring a safe milk-supply for large cities, or when pasteurization is accepted in lieu of testing cows for tuberculosis or of instituting adequate inspection of dairies for contagious diseases.

Secondly, pasteurization is resorted to as a means of securing a safe milk-supply that could not otherwise be procured in large enough quantity to supply our rapidly increasing urban populations. In this case the pasteurization must be controlled and cannot be carried out in the manner ordinarily practiced in a purely commercial way for the simple purpose of enhancing the keeping qualities of the product.

Municipal authorities are becoming more and more active in safeguarding of cities against frequently contagious and infectious diseases, and in this work have frequently traced such infections to the milk-supply.

The need of safeguarding milk-supplies is becoming more and more imperative by reason of the relatively low price of milk and milk products, which has compelled the farmer to practice intensive dairying in order to make the business at all profitable. This has reacted on the dairy cows. The animals have been kept with the prime object of minimizing loss of energy. Exercise in the open air has been sparingly allowed. In housing the proper means of ventilation and lighting have often been disregarded. With these essential conditions neglected the resistant forces of the overworked dairy cows have been materially lowered, and a field has been prepared for the spread of tuberculous infection.

The effort thus far made to eradicate tuberculosis in cattle has served to demonstrate very clearly that for the present at least the killing and disposing of all tuberculous animals is impractical. Compensation by the state for animals condemned and destroyed is in many sections impossible on account of the magnitude of the valuations involved. The segregation of the animals according to the Bang system necessitates the pasteurization of the milk, if it is to be used. This pasteurization, in order to be effective against the spread of tuberculosis, must be properly carried out.

Our efforts to inspect the dairy farms supplying our large cities, for infectious diseases, such as typhoid fever, scarlet fever, etc., are at present rendered ineffective by the concerted opposition of the dairymen, physicians in charge of the cases, and health officers residing in the rural communities.

It is certain that this factor of human contagion cannot be controlled in Chicago without increasing the present force of inspectors manifold. From a medical standpoint, it will always be difficult or impossible to recognize the prodromal stage of measles, incipient tuberculosis, abortive cases of scarlet fever, mild non-exudative cases of diphtheria, and especially the so-called typhoid carriers.

The only practical way to eliminate the spread of contagious diseases under present conditions seems to be the proper pasteurization of the milk; and here again improper pasteurization would serve merely to foster a false sense of security. If the public is to be safeguarded, it must be adequately safeguarded, and this means that pasteurization practiced for the purpose of destroying the disease-producing bacteria must be subject to control by health authorities.

In taking up the subject of control of pasteurization, due consideration should be given to the various kinds of standards which may be made use of. These for the purposes of this paper will be classified under the following three headings: (1) chemical standards; (2) physical standards, and (3) bacterial standards.

CHEMICAL STANDARDS

Chemical standards have been suggested from time to time for control of the pasteurized product, but in practice they have not proved satisfactory. It is a well-known fact that milk heated above 176 F. fails to show the blue color when the Stork test for enzymes is applied. Our investigations have shown that the results obtained by this reaction are not very uniform and are dependent on a number of factors, including primarily the degree of temperature, and, to a certain extent, the time of exposure. Pjaden, working in the Kaiserliche Gesundheitamt, found that the amount of peroxidases on which this reaction depends varied considerably in the milk obtained from different breeds of cows. Finally, it is of great importance to recognize that certain bacterial products developing in consequence of bacterial multiplication in pasteurized milk have the property of transferring oxygen, and hence may be classed with the peroxidases. The other reactions for peroxidases, such as the guaiac test and the aloin test, are subject to the same influences and errors as the Stork reaction. Practically, then, the Stork test, or any test depending on the recognition of the peroxidases in the milk, is valuable only in determining that the milk has been recently heated above 176 F. It would of course also serve to detect all forms of boiled or sterilized milk.

The tendency at the present time, however, is to heat to as low a temperature as possible and only for a period such as will serve to kill all pathogenic organisms and a sufficient number of saprophytes, and at the same time preserve the natural flavor and chemical composition of the milk. Exposure to heat above certain limits so alters the physical condition of milk that the cream does not rise naturally, but remains more or less completely emulsified. The public commonly judges the quality of milk by the amount of cream that has risen, especially in bottled milk, in which the cream line can be so clearly determined. Thus the demand to apply sufficient heat to destroy the peroxidases would necessitate the production of a pasteurized product of inferior commercial value, speaking of values as they are now appreciated. Such a demand would necessarily be harmful at the present time to the business interests of the dealer who is trying to place on the market a safe milk.

---

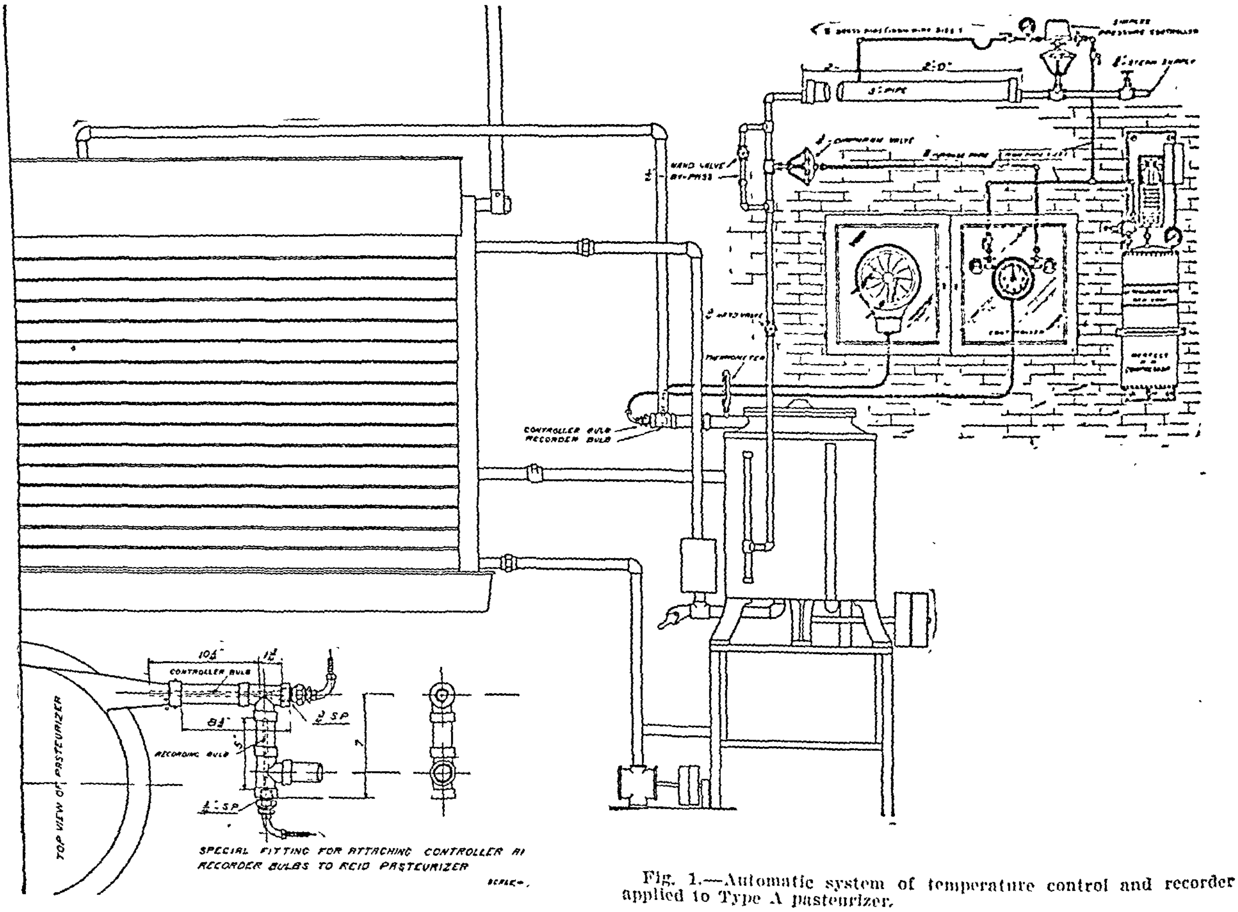

Fig. 1.—Automatic system of temperature control and recorder applied to Type A pasteurizer.

PHYSICAL STANDARDS

Physical standards, such as the degree of temperature employed and the time of exposure are most valuable in properly controlling pasteurization. In the case of continuous or so-called flash pasteurization, the degree of heat to be applied should be made to conform to certain minimum theoretical temperature standards plus such additional heat as may be required to kill about 99 per cent. of the bacteria in the raw product, both of which requirements will be discussed later. We have found that the time of exposure varies so much and is so indefinite of determination in the different types of flash machines, that it is practically impossible to prescribe the required amount of heat for a given type without determining this experimentally. The pasteurizer so operated should be equipped with a feed-pipe, which is so constructed that the pasteurizer cannot be fed in excess of its normal working capacity; that is, in excess of the working capacity of the machine at which 99 per cent. of the bacteria are killed when the required amount of heat is applied. After having determined either experimentally or theoretically the amount of heat required, it then becomes necessary to control this factor properly. This can be done most satisfactorily by equipping the pasteurizing machine with an apparatus regulating automatically the supply of heat or steam, so as to produce the required temperature of the outflow of the pasteurized product. Furthermore, a recording apparatus should be installed, to record during operation the temperature of the pasteurized product as it flows from the heater. The thermometer of this recording apparatus must be kept merged in the milk in such a way that it is not exposed to escaping steam or any other sources of heat than the heated milk. The records of the recording thermometer are made in a closed chamber, which may be kept under lock and key in the control of the sanitary officer or superintendent of the establishment, as the conditions may require. Daily temperature records show more accurately the lesser degrees of fluctuation, while weekly records are more convenient in those cases in which it is necessary to keep the records under lock and key in control of the sanitary officer. Temperature records kept in this manner indicate to the sanitarian the degree of efficiency, and to the operator of the plant are a valuable means of obtaining more perfect and uniform pasteurization. Commercially, this means less sour milk and less complaint from dissatisfied customers.

Whenever a holding device is employed whereby the milk is held at the temperature of exposure for a longer period of time, the control by graphic records becomes somewhat more difficult. The mechanism of the pasteurizer, or rather pasteurizing system, is more complex and of the two important elements, namely, the temperature and the time of exposure, the time of exposure is relatively difficult to control.

The temperature may be controlled by an automatic regulator and recording apparatus, as indicated for continuous pasteurization. The time of exposure, however, may be changed by changing the mechanism of the machine. Such changes can readily be detected by an inspector on the ground, but cannot be indicated by any simple graphic record, although practically such a recording apparatus could probably be constructed. Diagrams showing the construction of satisfactory temperature-regulating and recording devices are herewith appended.

a temperature of 71 C. or 160 F. for one minute is sufficient to kill the tubercle bacillus in milk.

For holding devices the heat requirements determined experimentally by Rosenau should guide us in determining the required time and temperature. Rosenau concluded from his experiments that tubercle bacilli and other pathogenic bacteria in milk lose their infective properties when heated to 60 C. (or 140 F.) and maintained at that temperature for twenty minutes, or to 65 C. (or 149 F.) for a shorter period of time.

The minimum temperature requirements usually set are, therefore, for the continuous type of pasteurizer, 160 F. for one minute; for the machine equipped with a holding device, 140 F. for twenty minutes.

The percentage reduction standard usually adopted is a 99 per cent. reduction in the bacterial content of the raw product. This, however, is not applied strictly, but in conjunction with a minimum allowable count of 100,000 per cubic centimeter, it being recognized that it is perfectly possible to produce a satisfactory product from initially good milk without an absolute 99 per cent. reduction, and on the other hand that a 99 per cent. reduction in an initially bad milk may still contain too many bacteria for safety. The strict application of the 99 per cent. standard places a premium on the use of raw milk having an initially high bacterial content. This is of course undesirable and is readily eliminated by application of the double standard (percentage reduction in conjunction with minimum allowable count).

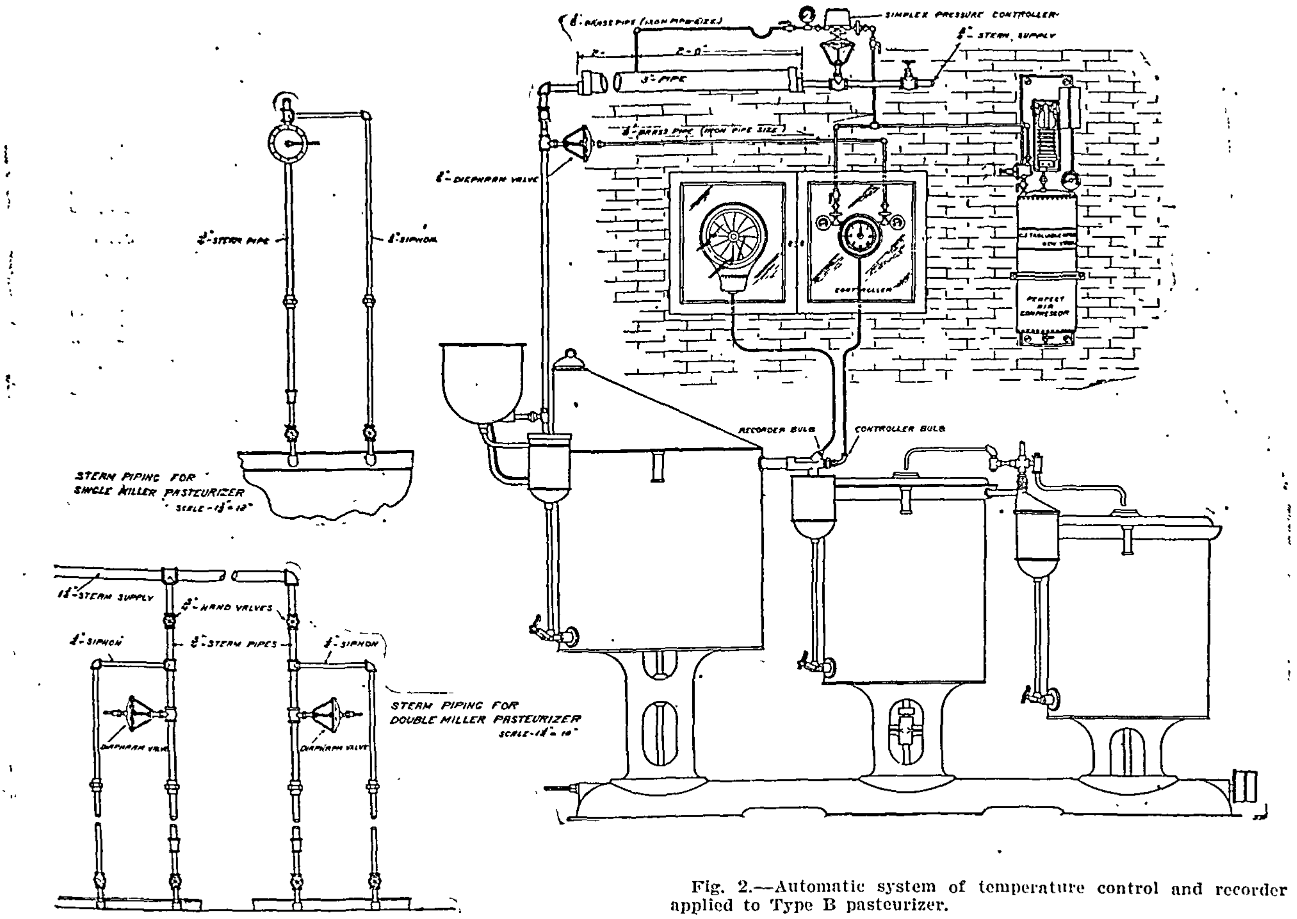

Fig. 2.—Automatic system of temperature control and recorder applied to Type B pasteurizer.

BACTERIAL STANDARDS

Bacterial standards should be threefold: a minimum temperature requirement, a percentage bacterial reduction standard, and a maximum permissible bacterial count.

Temperature standards should be determined by the thermal death-points, so far as we have definite knowledge of them, of the ordinary pathogenic bacteria conveyable in milk. A safe guide in the case of flash pasteurization is the degree of heat and time required to kill the tubercle bacillus, since it is the most difficult of the ordinary pathogenic micro-organisms to destroy, and inasmuch as one cannot hope to destroy spores with pasteurization temperatures. For this type of pasteurization, therefore, we should be guided by the results of Russell and Hastings, who determined that exposure to

During the past six months some seventy pasteurizing establishments have been subjected to bacterial investigation in the city of Chicago. A few representative results of these tests are here included.[1]

A study of the results of these seventy investigations reveals two interesting facts aside from the matter of temperature records. First, the percentage bacterial reduction under practical working conditions, as judged by the samples taken directly from the machine, is in general satisfactory for all five types of pasteurizers examined. Second, there is present in almost all establishments, irrespective of the type of machine used, a very constant and uniform element of recontamination. The significance of such recontamination may be considered from two angles, but depends in the last analysis on the extent to which it occurs. If the recontamination is extensive, it may mean practically the nullification of the work of pasteurization. In fact, instances have been noted in which the product of the plant contained more bacteria than the initial raw milk. On the other hand, if the recontamination is slight it may serve a very useful purpose, that is, it may be the means of introducing a few acid-forming bacteria, and thus improve rather than impair the quality of the product by causing it to sour naturally.[2]

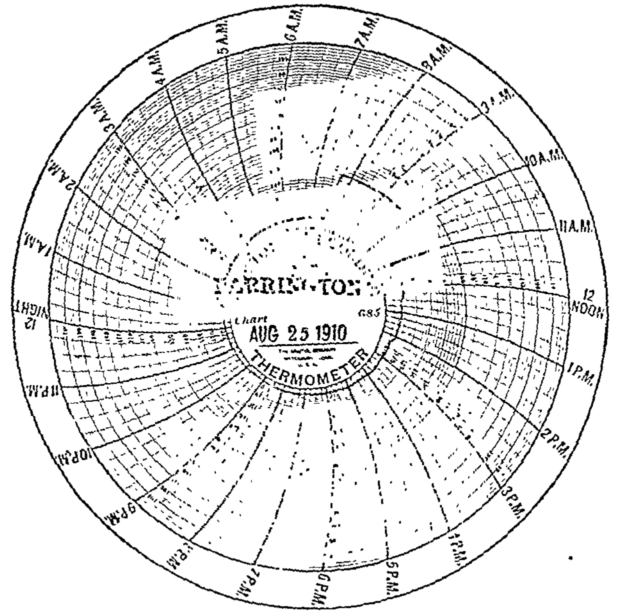

Fig. 3.—Graphic temperature record

If the bacterial count is sufficiently low to indicate a reasonable degree of safety from the standpoint of other bacteria, the reinoculation with acid-producers is of distinct advantage, inasmuch as it refutes the objection commonly raised that pasteurized milk putrefies when it is kept too long.

As a matter of fact, it is probably impossible in the control of pasteurization on a large scale to eliminate entirely the element of recontamination. Particularly

TABLE 1.—BACTERIOLOGIC INVESTIGATIONS OF PASTEURIZING PLANTS IN CHICAGO, JANUARY TO JULY, 1910

PLANT 1.—TYPE A MACHINE—CONTINUOUS *

June—Temp., 160° F.; cooled, 45° F.

Serial No.		Bacterial Count.
1376	Raw	17,000,000
1377	Pasteurized 160° F.	8,700
1378	From cooler 45° F.	55,000
1381	Bottled	120,000

PLANT 6.—TYPE D MACHINE—CONTINUOUS †

August—Temp., 165° F.; cooled, 48° F.

Serial No.		Bacterial Count.
2860	Raw	650,000
2861	Pasteurized from machine 165° F.	4,500
2862	Cooler 48° F.	7,600
2863	Bottle filler	127,000
2864	Bottle uncapped	108,000
2865	Bottle capped	66,000

PLANT 7.—TYPE B MACHINE—CONTINUOUS ‡

April—Temp., 160° F.; cooled, 54° F.

Serial No.		Bacterial Count.
979	Raw	69,000
980	Pasteurized 160° F.	2,000
981	Cooler 54° F.	14,000
982	Bottle uncapped	16,000
983	Bottle capped	14,000

PLANT 11.—TYPE E MACHINE—HELD-TIME, 10 MINUTES §

March—Temp., 150° F.; cooled, 60° F.

Serial No.		Bacterial Count.
570	Raw	50,000
571	Pasteurized 150° F.	4,500
572	Pasteurized, held 10 minutes	2,500
573	Pasteurized bottle filler	3,200
574	Pasteurized	8,500

PLANT 19.—TYPE E MACHINE—HELD 20 MINUTES

March—Temp., 147° F.; cooled, 60° F.

Serial No.		Bacterial Count.
803	Raw	5,000,000
806	Held in can 20 minutes	22,000
807	Cooler	36,000
808	Bottle uncapped	77,600
809	Bottle capped	84,000

PLANT 21.—TYPE F MACHINE—CONTINUOUS ||

March—Temp., 150° F.; cooled, 45° F.

Serial No.		Bacterial Count.
734	Raw	450,000
735	Pasteurized	7,000
737	Cooler	10,000
738	Bottler	10,500
739	Bottle uncapped	8,600
740	Bottle capped	50,000

PLANT 21

May—Temp., 150° F.

Serial No.		Bacterial Count.
1240	Raw	1,900,000
1241	Pasteurized 150° F.	8,000
1242	Cooler	9,000
1243	Bottle uncapped	9,300
1244	Bottle capped	16,000

PLANT 32.—TYPE D MACHINE—CONTINUOUS

May—Temp., 162° F.; cooled, 42° F.

Serial No.		Bacterial Count.
1139	Raw	1,500,000
1140	Pasteurized 162° F.	2,200
1141	Cooler 42° F.	1,500
1142	Bottler	2,000
1143	Can	8,500

PLANT 35.—TYPE B MACHINE—CONTINUOUS

January—Temp., 164° F.; cooled, 50° F.

Serial No.		Bacterial Count.
98	Raw	701,000
99	Pasteurized	2,300
100	From cooler	6,000
101	Bottled and capped	10,000

PLANT 51—TYPE E MACHINE—HELD 20 MINUTES

August—Temp., 143° F.

Serial No.		Bacterial Count.
2999	Raw	21,000,000
3000	Pasteurized 143°	56,000
3001	Held 20 minutes less than	1,000
3003	Bottle filler	18,000
3004	Bottle uncapped	16,800
3005	Bottle capped	17,900

PASTEURIZING MACHINES

* Type A.—A jacketed cylinder. Milk flows in at bottom, upward through center of cylinder and out at top. The jacket is filled with live steam.

† Type D.—Milk flows straight down over a heated cone.

‡ Type B.—A hollow cylinder with metal core. Milk flows in at bottom, upward in a thin stream between the core and jacket, and out at top. Heat is applied from outer jacket.

§ Type E.—Milk flows down in a spiral groove over a heated cone.

|| Type F.—A long trough in which hollow revolving disks are set at right angles to axis of trough. Disks are filled with steam. Milk flows along trough and is retarded by the disks.

Holding device may be attached to any of these types.

---

[1] For complete tables, see reprints.

[2] The fact that commercially pasteurized milk sours in the same manner as raw milk may be explained by one of two assumptions: (1) that there has been recontamination with acid-forming bacteria; (2) that a "resistant minority" of lactic acid bacteria has survived the heat of pasteurization. Ayers reports that a small percentage of the lactic acid bacteria may resist a temperature as high as 150 F., and also that one strain of *Streptococcus lacticus* had a thermal death-point of 168 F. (Bull. 126, U. S. Dept. of Agric., Bureau of Animal Industry). We are inclined to believe that the element of recontamination is the more important of the two, judging from the fact that samples taken from the pasteurizing machine proper do not usually develop acidity, while bottled samples taken from the same plants at the same time almost invariably develop about the same acidity as the raw samples.

is this true when there are numerous small dealers to be covered who cannot afford the services of a bacteriologist. Nevertheless, it is obvious that this point should be closely studied and the effort made to reduce the recontamination to a minimum. It is of course a bacteriologic problem, and should be handled by a trained bacteriologist rather than by the ordinary milk inspector who has had little or no laboratory experience. That there is much recontamination still going on in Chicago is to be expected considering the fact that the work of pasteurization is at present in a transitional stage.

The control of conditions at the pasteurizing plant, however, is fairly simple compared to the control of the conditions under which pasteurized milk is marketed. In a large city, this feature of the work is necessarily difficult. It means the additional necessity of securing proper methods of cooling, of preventing the practice of selling kept-over samples, and of educating the entire milk-producing and distributing industry in the proper care of the pasteurized product. It involves the uprooting of old preexisting practices, which have been in vogue for years and are therefore extremely difficult to eradicate.

From a study of the accompanying monthly averages of the bacterial counts of raw milk, pasteurized milk from plants, and pasteurized market samples collected in Chicago, it appears that the general run of the pasteurized market samples is considerably higher than that of the samples from plants, and that in a general way the bacterial counts of market samples follow closely the temperature curve of the weather.

TABLE 2.—MONTHLY AVERAGES OF BACTERIAL COUNTS, JANUARY TO JULY, 1910

	Total Examinations.	Average per c.c.	Per Cent. Below 500,000.
January, 1910.			
Pasteurizing plants	41	40,700	100
Pasteurized market	112	277,800	84
Raw	64	1,067,000	45
February, 1910.			
Pasteurizing plants	41	213,000	88
Pasteurized market	155	938,000	69
Raw	61	1,768,000	46
March, 1910.			
Pasteurizing plants	80	334,000	85
Pasteurized market	154	1,580,000	45
Raw	17	1,664,000	35
April, 1910.			
Pasteurizing plants	36	124,000	94
Pasteurized market	120	694,000	78
Raw	43	5,948,000	70
May, 1910.			
Pasteurizing plants	39	79,700	95
Pasteurized market	76	1,273,000	63
Raw	61	4,892,000	57
June, 1910.			
Pasteurizing plants	28	371,000	75
Pasteurized market	66	1,492,000	53
Raw	44	4,507,000	25
July, 1910.			
Pasteurizing plants	74	185,000	95
Pasteurized market	129	3,106,000	49
Raw	588	12,235,000	19

During the month of January, 1910, the average bacterial count of market samples was 277,800 per cubic centimeter; in February, 938,000 per cubic centimeter. In March, which was an unusually warm month for this time of the year, the average rose to 1,580,000 per cubic centimeter. With the cool weather of April it fell to 594,000, and in the warmer months of May and June reached 1,273,000 and 1,492,000 per cubic centimeter respectively, while in the heat of July the average of market pasteurized samples reached the excessive figure of 3,106,000.

Obviously the control of the marketing of pasteurized milk in Chicago is still unsatisfactory, although it should be noted that the averages of this product are in every instance lower than those of the raw milk for the corresponding period, and that the percentage of samples, which may be considered reasonably safe (under 500,000 per c.c.) is much greater in the pasteurized series than in the raw.

The lesson to be drawn from the above figures is clearly that the temperature at which the product is delivered or sold must be subject to control, as well as the process of pasteurizing, if a safe market product is to be supplied to the consumer. This can probably best be attained by the passage of an ordinance establishing a maximum temperature, say 50 F., at which milk may be transported, sold or held for sale. Until such a measure is obtained in Chicago, it is manifest that there will continue to be undue multiplication of bacteria in the interval between pasteurization and delivery to the consumer, especially during the warmer months of the year. Such an ordinance has been advocated during the past few months—and is now scheduled to come up for passage during the fall of 1910.

A study of the more detailed monthly reports[2] from which the above-mentioned averages are derived is interesting in that it gives a better idea of the general run of the bacterial counts, and brings out more sharply the contrast between the raw and pasteurized series.

TABLE 5.—PASTEURIZED SAMPLES, FRESHLY BOTTLED AND ONE DAY OLD, TAKEN FROM PLANTS

101	Freshly bottled	10,000
102	One day old	1,200,000
124	Freshly bottled	37,000
125	One day old	70,000
174	Freshly bottled	8,000
175	Freshly bottled	3,600
176	One day old	3,500
177	One day old	404,000
212	Freshly bottled	25,000
213	Freshly bottled	45,000
214	One day old	18,000
215	One day old	94,000
297	Freshly bottled	1,380,000
299	One day old	4,800,000
298	One day old	256,000
334	Freshly bottled	92,000
335	Freshly bottled	127,000
336	One day old	182,000
337	One day old	210,000
353	Freshly bottled	21,500
354	Freshly bottled	24,500
355	One day old	800,000
356	One day old	800,000
422	Freshly bottled	12,000
423	Freshly bottled	14,400
420	One day old	36,500
421	One day old	45,000
433	Freshly bottled	116,000
434	Freshly bottled	135,000
435	One day old	315,000
436	One day old	372,000
467	Freshly bottled	43,500
468	Freshly bottled	32,900
469	One day old	760,000
470	One day old	470,000

The detailed February report[3] of pasteurized market samples presents another important lesson which must be applied to the control of the marketing of milk, that is, the fact that many of the high bacterial counts in market milk occur as a result of the common practice prevailing in milk depots and retail stores, of selling left-over milk from the previous day's supply. This factor no doubt accounts for more of the high counts in pasteurized market milk than appears in the tables, inasmuch as it is not always possible for the inspector to obtain accurate information as to the age of bottled samples. Table 5, showing the bacterial counts of freshly bottled samples and samples one day old taken from pasteurizing plants, illustrates the extent to which bacterial multiplication occurs under ordinary practical conditions in the pasteurizing establishment proper.

---

[3] For this, see reprints.

To meet this phase of the problem an ordinance has been proposed for passage, which requires that the date of bottling or pasteurizing shall appear on every bottle of milk, both raw and pasteurized, offered for sale in the city of Chicago. This measure, if it successfully passes the city council, will make it possible for the consumer to determine at the time of purchase whether or not a fresh product is being vended.

By way of comparison, in order that the progress already made in the direction of a purer milk-supply, may not be lost sight of, Table 6 is submitted showing the condition of the raw milk during the month of July, 1910. These samples were taken entirely from railroad platforms and represent the condition of the milk as it arrives in the city during the warmer weather. The urgent need of protection of the milk-supply is well emphasized by these results, the average of which reaches the enormous figure of 12,548,000 per cubic centimeter.

RAW MILK TAKEN FROM RAILWAY PLATFORMS, JULY, 1910 [*]

Serial No.	Bacteria per c. c.	Serial No.	Bacteria per c. c.

183 Samples; 12,548,000 average bacteria per c.c.

[*] A portion only of this table is given here; for complete table see reprints.

At the present moment, it cannot be justly claimed that pasteurization in Chicago is under satisfactory control. In fact, little more can be done in this paper than to point out a few important lessons, which are to be drawn from the experiences of the last eighteen months. Results as shown by the some 4,000 bacterial examinations made during the present year are not ideal. Nevertheless, it is our belief that there has been a sufficiently great improvement over the raw product formerly sold in the city to justify the effort which has been expended.

Tumors in Cerebello-Pontine Angle.—T. Schwartz reports in the *St. Petersburg. med. Wochenschrift*, January 14, the details of two cases in which the syndrome was apparently identical and typical of a circumscribed tumor in the cerebellopontine angle. One patient died before the contemplated operation; the tumor in the other case was successfully removed at two sittings. Borchardt, who performed the operation, has compiled twenty-eight cases from the literature of the last two years with 50 per cent. recoveries. Schwartz states that his experience confirms the necessity for refraining from lumbar puncture in a case of a suspected brain tumor; in his first case although only 10 c.c. of fluid were released, intolerable headache followed and death occurred forty hours later, while removal of the tumor was being considered. In the two cases reported the Wassermann reaction was positive in the blood but not in the cerebrospinal fluid; necropsy revealed nothing suspicious of syphilis in the fatal case. The severe headache had improved and also the pulse under mercury and iodid in this case, evidently from the influence of the medication on the complicating hydrocephalus revealed by necropsy.

INJURIES OF ABDOMINAL VISCERA WITHOUT EXTERNAL SIGNS OF VIOLENCE [*]

HENRY H. SHERK, M.D.
PASADENA, CAL.

Subcutaneous or non-penetrating injuries of the abdominal viscera are of such frequent occurrence, and their early diagnosis so important, that it is somewhat surprising that they are not recognized earlier in the majority of cases than is the rule at present. A study of the early symptomatology of these visceral lesions is therefore desirable.

I shall consider only those injuries resulting from *external violence of such character as does not produce* any surface trauma of the abdomen, or at least leaves only slight evidence of external injury. I shall also further limit my subject by excluding injuries of the urinary tract.

Penetrating wounds of the abdomen naturally point to and make easy, comparatively speaking, the diagnosis of associated visceral lesions. When the internal injury is not accompanied by external abdominal trauma the diagnosis is usually difficult. Damage to other parts of the body often diverts the attention of the physician and the patient and the less apparent early abdominal symptoms are overlooked. Unfortunately, there are no signs that are pathognomonic of visceral trauma. In some instances symptoms appear early, while in others manifestations of the injury are delayed for hours or even days.

Many cases have been reported in which, after having suffered gross injury to some of the abdominal viscera, the patient has worked on for hours at hard manual labor before succumbing. In other cases the severity of the symptoms is often out of proportion to the existing lesions. Intense shock, pain and excessive vomiting may accompany an injury of no moment. The following case illustrates this:

CASE 1.—A. H., aged 45, male, at 4 p. m., four hours after last meal, while prying up the root of a tree with a pick, wrenched himself when the root pulled loose. He did not fall and was not struck on the abdomen. Pain in the splenic region followed immediately. It was sharp and lancinating in character, increased rapidly and was accompanied by nausea and faintness. I saw him twenty minutes after the accident, sitting on the edge of his bed, bending over with his hands pressed against his stomach. His skin was pale, cold and clammy with perspiration; pulse was rapid but fairly strong; respiration short and shallow; temperature 97.6 F. He complained of intense pain in the left hypochondriac region. There was some tenderness in the same region, and marked rigidity of all the abdominal muscles, especially in the left upper quadrant. Peristalsis was quite active and he had vomited once. Leukocyte count was 6,950. All symptoms gradually subsided, rigidity disappearing first. By the next day he was feeling all right except for a little localized soreness.

Cases have been reported in which mistaken diagnoses, based on alarming symptoms, have led to unnecessary operations. Again, the resultant injury often bears no relation to the degree of violence that produced it. Severe visceral lesions may follow slight accidents, and *vice versa*. For these reasons any symptoms, no matter how slight, referable to the abdomen, should be given due weight in any case in which the patient has been subjected to external violence. In no other class of cases is an early diagnosis so necessary. In most instances it is life-saving. A delayed diagnosis nearly always means a fatal termination.

---

[*] Read in the Section on Surgery of the American Medical Association, at the Sixty-First Annual Session, at St. Louis, June, 1910.

[*] For lack of space, an extensive table of cases is omitted from THE JOURNAL. It appears in the Transactions of the Section and in the author's reprints.

In discussing the subject I wish to consider the different elements wholly from the standpoint of their relation to the question of diagnosis, and shall take up:

1. The nature of the violence as a causative factor in the production of the injury.
2. The character and extent of the injury.
3. The symptomatology and diagnosis.
4. Deductions from a synopsis of cases collected from the literature.

As to the nature of the violence: Deaver's classification of the forces which cause injuries to the abdominal viscera as compressive, percussive and concussive, is sufficient. Each variety of violence tends toward certain forms of trauma. Therefore it is most important to ascertain, as definitely as possible, the exact details of the accident. How did the accident occur? Was the injured one's part in the accident active or passive? Was he struck by a rapidly or slowly moving, a large or a small, a hard or a soft object? Was the force great or slight? Was he crushed or run over? Did he fall from a greater or less height, or was he thrown some distance? What part of the body received the impact or the brunt of the violence?

Compressive or crushing violence, according to the way in which it is expended, may bruise, tear or rupture both the hollow and the solid viscera. When the violence is in the nature of a crushing force, a steady direct compression, the solid viscera can be crushed or torn, and the hollow ones can be torn, bruised or have their blood-supply damaged.

Compression applied over the abdomen in a progressive manner, as when the body is rolled in a narrow space between two objects, or run over by a heavy-tired automobile, may burst a loop of intestine. The solid or hollow organs may be torn loose from their supports in the same way. These injuries are possible also when the compression is produced by the forcible doubling up of the body, as in railroad accidents or when the subject, caught in a stooping or sitting position, is crushed by a heavy weight falling on his head or shoulders.

Extreme or violent muscular action can, under certain conditions, produce visceral injury.

By percussive violence we mean that received from the impact of a rapidly moving object. Horse kicks, a blow from a piece of wood thrown from a circular saw, or flying objects in an explosion, are examples of percussive violence. This form of violence may rupture the solid viscera and likewise the hollow organs, if they are distended at the time of the injury.

Both compressive and percussive force produce visceral trauma by direct violence.

When the impact of the violence is received on any part of the body other than the abdomen, visceral injury may result from concussion, or as one might say, by *contre-coup,* the force being indirect or transmitted. In this way the solid organs and the hollow viscera, when heavily loaded, can be torn loose at their point of attachment, the tears often extending into the substance of the organ. The following case illustrates the results of concussive violence:

Case 2.—R. T., aged 28, male, at 11 p. m. was thrown from a rapidly moving automobile, was struck on his shoulder but not run over; was able to crawl to the street curb and vomited before he reached it; was brought home in a state of collapse and was unconscious for two hours. He was ashy pale and vomited persistently. He complained of great pain in the upper abdomen and gave all the evidences of shock. There were bruises on the head, right shoulder and on the back near the right hip, none on the abdomen.

I was called in consultation the fourth day, two hours before death. The man was almost moribund and gave all evidences of profound general peritonitis. He had facies abdominalis to a decided degree. The abdomen was distended to its fullest extent and was tender all over. There was an entire absence of peristalsis. The liver dulness was obliterated and there was some dulness in both flanks, but the patient's condition did not allow me to determine if it was movable or not. The pulse was rapid and thready, about 140, temperature over 102 F.; respirations were shallow. The patient complained of great general pain and had vomited recently, what the doctor called stercoraceous matter. I was allowed only a partial postmortem examination. No bruises or ecchymoses on the abdomen. The abdominal cavity was full of fluid blood and clots and there had been general peritonitis. There was a tear, about an inch and a half long, in the liver along the falciform ligament. I could find no other lesion.

Sometimes the mere forcible jolting or jarring of the solid viscera causes rupture of their substance. This is more likely to occur if the organ is enlarged or softened by any morbid state. Wind concussion from explosions is another possible source of visceral injury.

Certain circumstances tend to lessen the liability to intra-abdominal injuries from external violence. The amount of clothing will sometimes soften the force of the blow, and at least prevent the occurrence of any surface traumatism. A fat abdominal wall will lessen the liability to injury from percussive force, while it might increase the danger if the force was either compressive or concussive.

Case 3.—R. B., aged 62, male, weight about 200 pounds, railroad superintendent, at 6 p. m., six hours after eating, accidentally fell or slid from the seat of a farm wagon. He dropped forward on the flank of the near horse, striking on the left lower ribs and upper abdomen. He fell only about three feet and struck against the rounded soft rump of the horse, and then slid off to the ground, landing on his knees. He was helped up and carried to the nearest house, a few rods away. He complained of intense pain in the region of the stomach. The doctor who saw him thirty minutes later found three lower left ribs fractured posteriorly and gave morphin to relieve pain in the upper abdomen. There were no marks of violence on the surface of the abdomen.

I first saw the man at 4:30 p. m. the following day, twenty-two and one-half hours after the accident. He was then lying on his back, slightly propped up in bed, with his knees drawn up. The expression on his face was anxious and indicative of suffering. The respirations were shallow and rapid; the pulse could scarcely be counted; temperature was subnormal. He was still vomiting and the abdomen was much distended and rigid. There was total absence of peristalsis. Great irritability of the bladder and constant desire to urinate were present. The patient's mind was slightly clouded, but he would rouse up enough to answer questions. There was great restlessness, with constant moving of the hands and arms. I made a diagnosis of rupture of the spleen and advised an immediate operation. Sudden collapse occurred soon after and the patient died before anything could be done, twenty-four hours after the accident. I was allowed to make a post-mortem examination of the abdomen only. The abdominal cavity was full of fluid blood and clots. There were two ragged tears near the upper border of the spleen. Death was due to hemorrhage.

I am sure that the weight of the patient and his fat abdominal wall influenced materially the results of what otherwise would have been an accident of no moment.

If the abdominal muscles are contracted and rigid in anticipation of a blow, as in athletic contests, the viscera are less likely to be injured than if the violence is unexpected and the abdominal wall is relaxed and soft.

The likelihood of internal injury being caused by external violence is materially influenced by the condition of the viscera themselves. The presence of morbid conditions in any organ greatly increases its liability to injury. An enlarged viscus, by its increase in size and weight, offers, as one might say, a larger target. A congested or softened spleen, or an inflamed and edematous intestine, is much more easily torn than a normal one. Adhesions resulting from previous inflammations, by abnormally fixing any organ, may increase its liability to injury from violence. One of my own cases is illustrative:

Case 4.—D. R., aged 61, male, dairyman, with history of having been gored in the abdomen by a bull twenty years previously, about 4:30 p. m., four hours after last meal, was stooping over to bandage a horse's leg and received a kick on the shin. As he straightened up he was squeezed between the horse's flank and the side of the stall, the abdomen receiving the brunt of the violence. When helped to his house a few minutes later he complained of great pain in the lower abdomen, over and above the bladder. He was nauseated but did not vomit. He looked ashy pale and the skin was cold and clammy. When first seen, about half an hour after the accident, he was lying still with his legs flexed. He complained of intense pain in the lower abdomen and of feeling chilly. There was marked general rigidity of the abdominal walls and the greatest tenderness was in the left lower quadrant. No dulness could be demonstrated. Peristalsis was absent and there was irritability of the bladder. The patient still gave some evidence of shock, but the pulse was of fair quality and its rate only slightly increased. Respirations were short and shallow. A diagnosis of probable visceral injury was made, and immediate exploratory operation was advised but refused. The patient could not pass urine and was catheterized. The urine was negative and contained no blood. Nausea continued, followed after ten or twelve hours by vomiting. Absence of peristalsis persisted and there were no bowel movements. Abdominal distention commenced in four or five hours. The pain over the bladder steadily increased. By 8 o'clock next morning, about sixteen hours after the accident, the pulse was 115 to 120 and thready, and the temperature was over 100 F. The abdomen was much distended, tender and rigid. Death occurred about fifty-six hours after the accident.

Post-mortem examination, made by Dr. Stanley P. Black, disclosed general peritonitis with extravasated intestinal contents. The intestines were more or less adherent from inflammation following the accident of twenty years previous. On the right side an adherent loop of the small intestine had been torn at the point of adhesion, an opening slightly over 1 inch in length being present.

A stomach distended with food, fluid or solid, or with gas, is more easily bruised or torn than an empty one. Therefore the relation of the time of the last meal and stool to the time of the receipt of the violence is of importance.

The part of the body impinged on, when violence is received, materially influences the nature of the resulting injury.

If the blow is delivered on the lower abdomen, injury to the small intestine, sigmoid or caput coli, may be suspected. Blows on the upper abdomen are not apt to injure the intestine unless received in the middle line and so directed as to crush the intestine against the spine, in which case the omentum and mesentery are also frequently involved. Violence received in either loin offers little danger to the intestines, except possibly the colon or duodenum, on account of their more fixed relations.

Force applied to the upper abdomen in the middle or on either side, as well as when delivered in the lumbar region, may injure the liver, spleen or pancreas.

Violence, of a crushing or gliding nature, delivered on the abdomen, too high for the intestines or too low for the liver or spleen, most frequently injures the mesentery.

A blow over a hernial sac, containing an intestinal loop, is often productive of injury to the intestine.

The character and extent of the injury to the viscera will depend on the nature and degree of the force, its application and the condition of the abdominal contents at the time of the accident.

The injury may be in the nature of a contusion, a crushing of the tissues, a tearing or a rupture of any of the viscera or their supports and attachments. It will also vary according as the organ affected is hollow or solid.

The damage may be direct and immediate to the organ itself, or it may be indirectly caused by injury to the blood-supply of the viscera affected.

The extent of the lesion will vary greatly. It may range from a slight bruising or abrasion of the peritoneal covering of the part affected to an extensive laceration of the substance, or even more or less complete disintegration of the whole of the viscera involved.

The state of the abdominal walls and the condition of the abdominal contents materially influences the degree and extent of the injury.

In considering the nature of these abdominal injuries, it is well to take up the different organs separately, dividing them into two main classes, the solid and the hollow viscera.

The solid viscera may be bruised, crushed or torn. A rupture of a solid organ is practically the same as a tear, except as to the mechanism of its production.

According to most authorities, the liver is the most commonly injured of the solid viscera, except, of course, the kidneys, which I am not considering, but in the accompanying series of cases collected from the literature, injuries of the spleen outnumber those of the liver. The liver may be crushed when the compression force is severe and applied directly over the region of this viscus, but this form of injury is not so common as the tears resulting from indirect violence, in which case the rents occur at or near the attachment of the supporting ligaments. Another form of tear is practically a rupture of the liver tissue resulting from extreme jarring or shaking of the organ. This is more apt to occur if the liver is enlarged or softened.

The spleen is subject to the same traumatisms as the liver, except that rupture of the splenic pulp is, by far, the most common form of injury to this organ. The spleen is so much smaller and lighter than the liver that it is less likely to have tears in its substance resulting from traction on its supports. Its small size, deep-seated position, and its surroundings, also afford greater protection against direct crushing.

The enlarged spleen is much more liable to injury than a normal one. Consequently splenic injuries are more common in tropical or malarial countries. According to Cantlie, most of the tears or ruptures of the spleen occur on its inner surface, especially when the organ is enlarged, owing no doubt to the fact that the outer surface is tougher than the inner one. "A spleen can therefore have its inner surface ruptured by a blow on the abdomen over the splenic area, without any evidence of injury on its outer surface." This is due to concussion.

The normal spleen is most likely to rupture at the height of its functional activity, *i. e.*, some hours after eating.

Traumatism of the pancreas seldom occurs and is usually associated with injury of other organs.

The omentum and various mesenteries can be torn, bruised or crushed, but an injury to them is generally associated with corresponding traumatism to the intestine or other organs.

In women it is always well to remember the possibility of rupture of ovarian cysts or ectopic gestation sacs.

The hollow viscera liable to injury are the stomach, intestines, gall-bladder and ducts, the thoracic duct and the large blood-vessels.

The stomach may be torn in any of its parts, but the most common seat of injury is near the pyloric end. The tears may be small or extend completely across the stomach. When the latter occurs, it is always at the pyloric end (Deaver). The stomach is so well protected by its surroundings that it is seldom injured except when distended with food or gas, and in most instances injury of the stomach is associated with trauma of the liver or other viscera.

The intestines may be torn, crushed or ruptured. The injury may be slight or extensive, single or multiple, and may involve any portion from the pylorus to the rectum. The more fixed parts of the small intestine are most frequently affected, the upper end of the jejunum and lower ileum furnishing about 75 per cent. of all intestinal injuries, the duodenum nearly 5 per cent., the large intestine a little over 3 per cent., while 17 per cent. covers other parts of the small intestine. The extent of the rupture or tear is generally in proportion to the degree of violence.

When the intestine is crushed or torn by traction on its fixed points, the tear may be large. When it bursts from localized hyperdistention of one of its loops, resulting from external compression, the perforation in the inner coat is generally small and round, while the peritoneal coat is torn to a much greater extent, just as is seen in a blow-out of an automobile tire, the inner tube showing only a small opening while the outer casing is ripped open for several inches.

Tears and contusions of the intestine generally occur near its mesenteric attachment, while ruptures are usually found opposite the mesentery. When a loop of intestine, contained in a hernial sac, is injured, the lesion is apt to be single and in many instances the damaged intestine, as soon as it is relieved of its distention by leakage of gas and fecal contents, drops back into the abdominal cavity, leaving the hernial sac soiled with the extravasated matter.

Rupture of the gall-bladder or of the bile ducts is rare, occurring most frequently in the presence of stones or some prior pathologic condition of these viscera, and is almost always associated with trauma of the liver. According to Deaver the cystic duct is the part most commonly affected.

As it is an accepted fact that an early diagnosis is absolutely necessary if anything is to be done in these cases, the symptoms of the first few hours are the important ones. The later manifestations, coming on when the patient is beyond relief, are so easily appreciated that a discussion of them is not needed. I shall therefore confine myself, as much as possible, to the consideration of these earlier signs.

The fact that the symptoms vary so much and that none is constant, makes an early diagnosis, in most cases, a matter of extreme difficulty. In many instances it is practically impossible. For these reasons a diagnosis of suspicion or presumption should be adhered to until the element of internal injury can be positively eliminated.

Unfortunately, the severity of the early symptoms does not always correspond to the degree of injury. An extensive trauma may be followed by only slight primary manifestations. On the other hand, injuries of much less degree are often associated with a display of most alarming symptoms.

The train of symptoms is really governed more by the nature than by the degree of the trauma. In injuries of the solid viscera shock and signs of hemorrhage predominate, while a tear of the intestine or stomach is followed, more or less quickly, by the evidences of peritonitis. Where the intestine is simply bruised, without any perforation of its coats, or its mesentery injured the peritonitis may not develop until a necrosis permits leakage of its contents.

Pain is probably the most important symptom; not that it is the most constant or dependable one, but because it is generally the first and because it is the symptom that appeals most to the patient and influences him to apply to a physician for help. Unfortunately, it is often very slight and does not last long. It may be immediate or not appear for hours. Its relation to the degree of trauma is not a constant one, often being present in inverse ratio to the amount of injury. The character and severity of this symptom varies greatly. It may be slight or intense and agonizing. It is not like the pain of the ordinary functional or inflammatory abdominal troubles, but is like the pain that accompanies ruptured extra-uterine pregnancy, sharp and lancinating, as if something had given away or torn loose. It is often described by the patient as deep-seated and radiating. It is the pain of torn peritoneum and not that of inflammation, which appears later. The degree of the initial pain is often much influenced by the amount of shock present. In extreme shock the patient often makes but little complaint of pain, but as reaction sets in and the shock lessens, appreciation of his suffering becomes more evident.

The initial pain is generally localized, either at the site of the injury or at some point more or less distant, even beyond the region of the abdomen. The secondary or inflammatory pain follows the course of the extravasated blood or visceral contents, and as a rule is more generalized. Therefore this initial pain is important only as it calls our attention to the fact that an injury has occurred and that it may, by its location, indicate the probable site of the injury.

Next to pain, shock, varying in degree, is the most common accompaniment of intra-abdominal injuries. Like pain, it does not bear a constant relation to the gravity of the injury, but generally speaking the greater the injury the more profound the shock. The mere presence or the amount of initial shock, *per se*, is of no real diagnostic value and if profound often obscures rather than helps to make a diagnosis. Contrary to this, its progress or course is of the utmost import from a diagnostic and prognostic standpoint.

Rupture of hollow viscera is likely to be associated with early and deep shock, from which the patient rallies, except in the few instances in which the nature and extent of the injury is sufficient to cause death quickly. On the other hand, lacerations of the solid organs, in which hemorrhage is the cause of the symptoms, produce shock, which though slight at first steadily increases as the hemorrhage continues.

Progressively deepening and secondary shock are most serious manifestations.

Nausea and vomiting are often early symptoms, but as a rule do not appear until a short time after the occurrence of the accident. Early vomiting is not of much importance, but persistent or late vomiting is usually indicative of serious injury. The quality of the vomitus will sometimes aid in diagnosis. The presence of blood in it will indicate trauma of the stomach or duodenum, but its absence will not exclude injury of these viscera. In large tears of the stomach vomiting is likely to be absent, or if present may or may not contain any blood.

Tenderness, either local or general, is commonly found. If early it is usually quite marked over the seat of the visceral injury. Later on when peritonitis intervenes, after rupture of the stomach or intestines or following marked hemorrhage, the tenderness, together with the pain, becomes general or may appear at a point quite distant from the site of the injury.

Another symptom closely associated with tenderness is rigidity. This may vary from a slight local stiffness or tenseness of the muscles to a board-like rigidity of the whole abdominal wall. This condition, in degree, bears a more definite relation to the amount or seriousness of the internal injury than any other manifestation. As a rule it occurs early and from that standpoint, although it may last only a short time, is of the utmost importance in helping to a timely diagnosis. When localized it bears a general relation to the site of the injury and often, in the absence of other leading symptoms, indicates the part of the abdomen to approach in operative procedure. Where there is general rigidity close observation may distinguish a greater resistance in some one part than in others. A board-like rigidity of the whole abdominal wall, when associated with shock, vomiting and pain, following any form of external violence, is always to be taken as presumptive testimony of serious injury. According to Deaver the so-called "checkerboard" abdomen is almost pathognomonic of grave intra-abdominal lesions.

Some rigidity may be present with bruising of the abdominal walls, but it does not progressively increase. Usually it is not apparent under light palpation, appearing only when pressure is made on the bruised and tender muscle.

Distention is generally a late accompaniment of trauma of the abdominal viscera. When it appears early, to any extent, it usually means gross injury with extensive extravasation of intestinal contents, both fluid and gas. The distention that appears later and comes on gradually is the result of intestinal paralysis, the earliest sign of which is lessening or cessation of peristalsis. This diminished or absent peristalsis is, to my mind, one of the most important signs that we have, though in the cases reported and in the articles written on this subject it is rarely mentioned, but one or two writers laying any stress on it. I think I place more dependence on it than on any other symptom, not only in the class of cases under consideration, but in the matter of diagnosis of all acute inflammatory and accidental troubles of the abdominal cavity, whether of internal or external origin. I think auscultation is as important as an aid to diagnosis in abdominal diseases as it is in those of the chest, and yet I know of no other means of examination that is so universally neglected. O. C. Gaub of Pittsburg has shown experimentally that peristalsis is obliterated very quickly, after a blow on the abdomen, to return inside of a few hours if the resultant injury is not serious. He reports some cases, in which operation was performed in the presence of peristalsis, other symptoms indicating visceral trauma, in which no injury could be found. Claybrook also emphasizes the importance of this symptom.

Early aperistalsis may only indicate that the abdomen has received some shock or violence, and does not necessarily show that an injury has been done, but if three or four hours after the violence, when reaction has taken place, there is still silence on auscultation and this condition persists, it is almost conclusive proof that the injury is of some moment. When aperistalsis recurs, or when it commences some hours after the receipt of the injury, it is always indicative of serious trouble. It appears more promptly and is more complete and persistent with perforations of the intestines than when associated with other visceral lesions.

Dulness on percussion is not a very dependable sign. If a movable area of dulness can be positively demonstrated, it is good proof that a quantity of fluid, blood or intestinal contents, is free in the peritoneal cavity. But a moderate amount of gaseous distention will obscure it and fresh adhesions will prevent the movement of the fluid when the body position is changed. The absence of liver dulness, asserted by some to be almost pathognomonic of intestinal perforation, is certainly deceptive.

The expression of the patient's face is of prime importance; the so-called facies abdominalis is a frequent accompaniment of serious visceral lesion. It is not a part of the symptom-complex of shock and, as a rule, does not appear until reaction sets in. It is rarely absent, but it may be present to only a slight degree. It is practically always absent when the injury is trivial. The expression is one of distress and anxiety, as if the patient were conscious of impending danger.

Early restlessness is common, especially when the amount of shock is slight. On the other hand, the patient lies quietly if there is profound shock, or, when, later, the peritoneum is inflamed. A reclining posture is generally assumed, the patient lying on his side with the thighs flexed, or he may sit up, leaning forward, with the knees drawn up toward his chin.

Thirst is quite common, especially when there has been much hemorrhage. In a few cases bowel movements occur early, but when the injury is of any extent, especially when the intestine is involved, the paralysis of the intestine precludes all possibility in that direction. A movement containing blood, if it does occur, may be of some value, according to the nature of the blood, in determining the location of the intestinal injury.

Irritability of the bladder is a common and moderately early symptom, commencing as soon as the pelvic peritoneum is irritated by the presence of a quantity of blood or infected by escaped bowel contents. It is in reality one of the earlier manifestations of a commencing general peritonitis, septic or otherwise. The urine in most instances will be negative unless the bladder or kidneys are involved, therefore its examination is useful only in eliminating the question of injury to these organs.

The temperature and pulse are those of shock, internal hemorrhage or peritonitis. The initial temperature is apt to be subnormal, rising as reaction sets in and going above normal with the development of peritonitis. An early, rapid and marked rise of temperature following abdominal injury is suspicious of intestinal rupture and leakage. A secondary fall of the temperature, to below normal, is indicative of serious trouble (Le Conte).

The pulse is variable, rapid, weak and thin if there is much early hemorrhage associated with shock. A pulse, of good quality at first, steadily losing in strength and quality, indicates progressive hemorrhage. According to Le Conte, a steadily rising pulse, after reaction has taken place, is a bad sign, but it must be associated with other symptoms to be alarming.

Dirt marks and tears of the clothing are of value, as are also superficial bruises, in determining the nature of the violence and its point of impingement, and should always be investigated, for, in the absence of a definite history of the accident, either may be the decisive factor.

While an accurate or differential diagnosis is not essential, still it is desirable, to say the least. What is essential, however, is the ability to recognize that certain combinations of symptoms are presumptive of pathologic conditions which, if left to themselves, will jeopardize the life of the patient. It is not necessary to say that the intestine is torn or the spleen ruptured to be justified in advising operative treatment. To know, however, that some viscera has or has not been injured enough to necessitate operation is what is demanded.

A careful study of the initial symptoms, the character of the violence, and the part of the body receiving the force, should indicate the region of the abdomen containing the injured viscera.

A differential diagnosis, other than a presumptive one, is an extremely difficult matter, but certain symptoms when present are of differential value.

As stated before, an early appearance of signs of peritonitis is indicative of injury to a hollow viscus, while symptoms of hemorrhage point to trauma of one of the solid organs. In the latter case peritonitis is generally a late manifestation.

In rupture of the pyloric end of the stomach or of the duodenum the initial pain will be epigastric, but a little later is apt to be referred to the right side in the region of the appendix, as has been pointed out by Moynihan, in duodenal perforation from ulceration.

When the tear is near the cardiac end the pain will be more on the left side, gradually becoming lower as the extravasated stomach contents gravitate along the descending colon. If the tear is in the posterior wall the leakage is into the lesser peritoneal cavity, the resulting peritonitis is limited, and the accompanying pain is also more or less localized. The local pain of a ruptured stomach is often described as gnawing or burning in character.

In ruptures of the intestines the primary pain is usually local, but quickly becomes general. The lower in the intestinal tract the perforation occurs the more intense will be the peritonitis.

An empty condition of the stomach and intestines defers the appearance of peritonitis. When necrosis of the intestine follows injury to its mesentery, the sudden onset of symptoms, accompanying perforation, frequently occurs just after the ingestion of food.

The obliteration of peristalsis is one of the most important signs of perforation of the intestines or stomach. It is a most constant symptom and rarely absent.

The primary symptoms of injury of the mesentery are those of hemorrhage.

The pain of liver injuries is more or less influenced by anything which involves movement of the diaphragm, especially when it is sudden or excessive. It is intensified by hiccoughs and vomiting. Inspiration increases it and accordingly respiration is embarrassed. The pain is often referred to the right shoulder.

In injuries of the spleen precordial pain is often present and sometimes the pain is referred to the left shoulder. Air hunger and shortness of breath are prominent. Ballance's sign, dulness movable on the right side but not on the left, due to the formation of clots near the spleen, may be present when the splenic hemorrhage is slow.

When the pancreas is ruptured, torn or crushed, the hemorrhage or fluid accumulating in the lesser peritoneal cavity may create a cyst-like tumor. The pancreatic secretion induces peritonitis very quickly. The early presence of sugar in the urine is suggestive of pancreatic involvement.

The symptoms of rupture of the diaphragm are those of diaphragmatic hernia, but as the former is ordinarily associated with trauma of other viscera, its manifestations are obscured and it is practically never recognized before operation or autopsy. However, the signs of pneumothorax following an abdominal injury, when the usual causes of air in the pleural cavity can be excluded, point to a possible tear in the diaphragm. Hiccough also suggests injury to the diaphragm.

Rupture of aneurysm of the abdominal aorta or of any of the blood-vessels produces symptoms practically similar to those of rupture of the stomach, but in most instances death follows quickly. If the rupture of the vessel is not complete and a traumatic aneurysm is produced, the symptoms, although intense at first, do not progress as when the stomach or intestine is torn. The signs of peritonitis are lacking.

I have collected reports of some 350 cases of subcutaneous injuries of the abdominal viscera. Of these only 290 were available, as the rest were so lacking in details as to be of no use whatever. I have used those cases only in which actual visceral injury was either verified or disproved by operation or post-mortem examination. Of those tabulated* only a small proportion contained sufficient accurate data on which to base any deductions. Most of them were inaccurate and indefinite. Fully 20 to 25 per cent. did not mention or were indefinite as to the time of operation after the accident. About 2 per cent. left one in doubt as to whether the patient lived or died.

In the following figures I have added, to the 290 tabulated cases, three of my own reported in this paper. The causes of injury were as follows:

Explosion, 1; strain, 4; blows, 86; kicks, 51; run over, 38; falls, 53; thrown, 15; crushed, 42; not stated, 3.

The intestine was affected 181 times; liver, 22; spleen, 45; pancreas, 25; omentum or mesentery, 14; diaphragm, 5; ovarian cyst, 1.

Pre-operative or antemortem diagnosis was stated as made in 101 out of the 293 cases. Of these 101 diagnoses 28 were general, 17 were probable. 38 were accurate and 18 were wrong.

Of the 18 incorrect diagnoses, most were wrong as to the nature or location of the injury and not as to the fact.

In 9 cases the reporters frankly stated that no diagnosis was made, while in 183 cases the matter of diagnosis was not even mentioned. It is to be presumed that a diagnosis was not made in these cases.

In percentages, no diagnosis, 65.5 per cent.; wrong, 6.1 per cent.; probable or general, 15.4 per cent., and accurate or correct, 13 per cent.

One hundred and thirty-two patients died, 155 recovered, and the results were not stated in 6. They were divided as follows:

TABLE 1.—OUTCOME OF CASES

	Intestine.	Liver.	Spleen.	Pancreas.	Omentum and Mesentery.	Diaphragm.	Ovarian Cyst.
Died	94	11	10	10	2	5	0
Recovered ...	82	11	34	15	12	0	1
Not mentioned	5	0	1	0	0	0	0

Of the 293 patients 257 were operated on and 36 were not operated on.

Of the 36 patients not operated on all died.

Of the 257 operated on 96 died, 155 recovered and the results in 6 were not stated.

---

* As stated in the introductory footnote, the table is here omitted.

would number, in the aggregate, at least 50,000, with so small a mortality that it would be a negligible factor. And yet there is a certain risk which should be avoided in advising operation on inadequate study. When a surgeon advises a young girl to have the appendix taken out, and bases that advice on her saying that she has appendicitis, and on a physical examination which consists in leaning across his office table and pressing with his fingers on the right iliac fossa, through the clothing, corsets and all—I call that the extreme of absurd opinion and unjustifiable advice.

In abdominal trauma, whatever the cause, we must not wait until there is muscular rigidity, vomiting and distention. We all know that when these symptoms are present operations succeed only by a miracle. In chronic abdominal disease the benefit of the doubt means conservatism. Study the case with care and deliberation. What you lose in time you gain in prognosis. In acute abdominal emergencies, especially the traumatic, the benefit of the doubt means radicalism. Make the diagnosis with speed and operate immediately. What you gain in time you gain in prognosis. I could give my personal experiences, which have forced me, rather against my natural tendencies, to become extremely radical in the presence of sudden and severe abdominal symptoms, whether traumatic or not. If the surgeon ever needs to be prompt in the application of operative measures for the relief of acute abdominal symptoms, he must be prompt when those symptoms follow violence to the abdominal wall.

THE SECRET COMMISSION EVIL*

J. P. LORD, M.D.
OMAHA

There seems to me to be a greater need to discuss one of the ethical questions agitating the surgical world to-day, than to add another scientific paper. It has seemed to me that specialism, with all the advantages and benefits which it has brought to mankind, enabling specialists to render such distinct service to humanity, and thereby enhancing public confidence and esteem, has not been an unmixed blessing to the professional body. The new conditions, changed relations, variable rewards, and readjustments in the relationships of patient, family physician and specialist, together with new economic conditions, as developed by our numerous public and private hospitals, dispensaries, laboratories, corporation work, indemnity insurance, lodge and society practice, have brought problems for solution by the profession in general, and our specialty in particular. The commercial spirit, with which the present age is now credited, has added another factor, the control of which we, with our somewhat neglected code of ethics, have not kept. The rapid development of specialism, with its special rewards and the keen rivalry incident thereto, has developed a new order of things professional, the ethical adjustments of which have not yet been generally made.

There has been so much said on this subject that it would seem almost puerile to attempt to say more. Indeed, it is not my purpose to try to improve on what has already been so well and so fully presented. Realizing as I do that it is probably true that the practice of fee division, secret division, joint fees, commissions, so-called dichotomy, graft, and possibly obtaining money under false pretenses, is increasing, especially among the younger element, I undertake to arouse our members from their seeming lethargy. We teachers and hospital surgeons, as a rule, are established in our respective communities, and have not felt the force of this evil to so great a degree as to compel action. Those who follow will feel it keenly. Many young men are wrestling with this moral problem and will yield to the general trend of practice unless some aroused moral force within the profession, or the effect of publicity, checkmates this menace to professional honor, dignity and common honesty. I agree with those who favor publicity as the speediest and most effective remedy. Then, too, we need some Roosevelts to keep up a rapid-fire attack on this practice.

We should maintain a sentiment against any countenance of graft. Its devotees should not be given positions of honor. They should learn the penalty for unfair and unmanly competition. The present standards of membership of this society should prevail, and we would do well to revise our membership lists, since we have a considerable number who do business on a commercial basis. Our body is not in a position to reform the other fellows when we, too, are culpable. Scarcely a man among us is in a position to cast the first stone, but there are many who have recoiled from this thing on the discovery that this temptress had assailed their manhood and their integrity, and that they had actually violated their patients' confidences.

In writing on this subject several years ago I made the statement that the division of fees was not itself so bad as that to which it leads. The road is short and direct to the practice of graft. This may be a seemingly harsh term to apply to some of the more respectable forms of secret fee division. Secrecy, however, makes it dishonest and renders possible all forms of abuse. The results of the practice are so manifestly demoralizing as to cause all those who love their profession and cherish its sacred traditions, and who seek to uphold its honor and good name, to array themselves in opposition to those who seem concerned only for the monetary rewards of to-day.

It has been observed that those practitioners who work on a commercial basis are too prone to lose sight of the patient in their efforts better to serve their immediate selfish ends. Their lack of thorough conscientiousness leads them into questionable methods. They handle cases as merchandise instead of treating them as patients. This causes them to hold on too long before advising operation, and then to recommend operation on a moribund patient. Their zeal to have people operated on who are willing, causes them to work up cases, and this working-up process sometimes is so considerable that they claim compensation for it. The service is often times considered by them of monetary value equal to or greater than the skilled and experienced services rendered by the surgeon, who has possibly made or caused to be made various laboratory tests, and exhausted every resource to complete a diagnosis, and who has done the operating and given the after-care.

The specialists with their hospital connections and the valuable facilities for advanced and successful work, and the resulting wealthy and large clientele, cause the envious to consider that these men have the best of it, and they are willing to adopt grafting as their most ready means to easy money.

The practitioners who have for years adhered to an inelastic fee-bill find themselves with their financial wings clipped, and unable to rise above the level of customary fees. The specialist is somewhat of a law to himself and most often gets what he asks. These practitioners, therefore, avail themselves of the specialist's facile faculty of fee-getting, by requesting t[illegible]t

TABLE 2.—LENGTH OF TIME WHICH ELAPSED BETWEEN RECEIPT OF INJURY AND OPERATION

Operation following injury.	Total Cases.	Died.	Recovered.	Result Not Stated.
Within the first 6 hours	64	15	48	1
In the second 6 hours	36	12	24	..
In the third 6 hours	29	14	13	2
Over 13 hours	78	35	42	1
Indefinitely stated but presumably early	13	7	6	..
Time not stated	37	13	22	2

In injuries of the intestines the mortality of the patients operated on in the first six hours was 20 per cent.; the second six hours, 35 per cent.; third six hours, 56 per cent., and over eighteen hours, 66 per cent. Of the liver, first six hours, 71.5 per cent.; second six hours, 50 per cent.; over eighteen hours, the mortality was *nil*. Of the spleen, first six hours, 8.6 per cent.; second six hours, 40 per cent.; over eighteen hours, only 16.6 per cent. Early and late operations for injuries of the pancreas resulted in 29 per cent. and 33.3 per cent. mortality, respectively.

No definite conclusions can be reached as to the frequency of the various symptoms, as the majority of the cases were so indefinitely reported.

In the following figures I refer only to the symptoms of the first few hours:

In the reports of 265 cases pain was mentioned 182 times; as decided pain in 147 cases, slight in 29 and absent in 6; it was not mentioned in 83 cases.

Shock was mentioned 94 times; severe in 46, mild in 31 and absent in 17; not mentioned in 171 cases.

Rigidity was mentioned 159 times; marked in 125 cases, slight in 20 and absent in 14 (in about half of the 14 it appeared as a later manifestation); it was not mentioned in 106 cases.

Peristalsis was only mentioned in 5 instances; absent 3 times and present twice; in the two latter cases operation disclosed no trauma.

A study of these statistics will show the following:

The mortality of injuries to the abdominal viscera, from external violence—over 40 per cent.—is much higher than of corresponding lesions resulting from other causes, and is due no doubt to lack of early diagnosis and to operative hesitancy.

The death-rate of early operations averages less than one-third that of late operations.

The more commonly observed symptoms, pain, shock and rigidity, were present early in a large majority of the cases; pain 97 per cent., shock 82 per cent., and rigidity 90 per cent.

Peristalsis, one of the most important signs, was noticed or mentioned in less than 2 per cent.

SUMMARY

Anyone who has been subjected to external violence of such nature as could, either directly or indirectly, produce injury to any of the abdominal viscera, should be given the most careful examination, and be kept under close observation for several days. Any symptom, no matter how slight, referable to the abdomen, must be considered as a sign of possible visceral injury when it follows the receipt of any violence, regardless of the point of impact or the extent of the external force.

The degree of violence bears no relation to the extent or severity of the resulting injury.

A most thorough investigation as to the exact details of the accident is important as an aid in determining the possibility and the nature of any injury.

Blows, kicks, and crushing violence produce most of the intestinal injuries, compressive force is the most common cause of trauma of the liver, and concussion is responsible for most of the splenic ruptures.

The presence or absence of peristalsis is of the utmost importance from a diagnostic or prognostic standpoint. Its early presence indicates that the abdomen or its contents have received some shock or violence. The persistence of recurrence of this sign is conclusive proof of internal or visceral injury. A decided lessening of peristalsis is a danger-signal if it occurs more than three or four hours after the accident. Active peristalsis is always encouraging in the presence of any abdominal injury.

There are no symptoms that are pathognomonic, most of them being common to all injuries, but, in general, progressively increasing shock indicates trauma of the solid organs, while early symptoms of peritonitis follow tears of the stomach or intestine.

Pain as an initial symptom is important only in that it calls attention to the fact that an injury may have occurred and that it may by its location indicate the possible site of the trauma.

Shock possesses no real diagnostic value except as to its progress or course, which is of the utmost importance.

I also wish to emphasize this fact: that an exact diagnosis is not necessary, though it is highly desirable, and that the early recognition of the probability of visceral injury is absolutely essential to lower the death-rate in these cases.

Appreciation of possibilities, or, as Murphy has aptly expressed it, "a keen surgical sense," is what is needed by the doctor who first sees the patient.

268 South Orange Grove Avenue.

ABSTRACT OF DISCUSSION

Dr. Garry D. Hough, New Bedford, Mass.: There is one diagnostic sign in cases of internal injuries of the abdomen which was not referred to by Dr. Sherk. It is not always present—perhaps in only 30, 40 or 50 per cent. of cases. When present, it tells you exactly where the trouble is located. That sign is the hyperalgesic zone, which corresponds to the injured viscus. In 1893, an Englishman first brought out the fact of a hyperalgesic zone corresponding to disease in an abdominal viscus. When this sign is present, so far as cumulative experience can yet tell us, it is an absolutely certain thing, but unfortunately it is present in only about half of the cases.

Dr. Maurice H. Richardson, Boston: A most important point which is emphasized in this paper is abdominal diagnosis. In an abdominal case, the greater the difficulty of diagnosis the greater the interest, and the greater the satisfaction when exploration shows that diagnosis correct. Except in urgent cases, I take any amount of time necessary to come to a positive conclusion. But there is reason in all things. After violent blows on the abdomen, to wait for symptoms enough for a positive diagnosis is to let pass the only opportunity for successful intervention—so, too, in perforations of the alimentary canal, and in duodenal and gastric ulcer. On the other hand, it may save the patient an unnecessary exploration if the surgeon takes days, or even weeks, to make a diagnosis.

In teaching, I stand for extreme care in diagnosis, especially abdominal—for the exhausting of every symptom in the history, and of every sign in the physical examination, and for the education to the greatest nicety of the powers of observation and deduction, before subjecting a patient to even the slight risks of exploration. But when we come to abdominal emergencies we cannot wait. In large communities, where these acute emergencies are common, we cannot and do not wait for a positive diagnosis. We must feel assured that there is a reasonable certainty that some serious lesion demanding surgical remedy is present. The dangers of the exploratory operation are, of course, slight. I could pick out twenty-five men in this audience whose operations for chronic appendicitis

would number, in the aggregate, at least 50,000, with so small a mortality that it would be a negligible factor. And yet there is a certain risk which should be avoided in advising operation on inadequate study. When a surgeon advises a young girl to have the appendix taken out, and bases that advice on her saying that she has appendicitis, and on a physical examination which consists in leaning across his office table and pressing with his fingers on the right iliac fossa, through the clothing, corsets and all—I call that the extreme of absurd opinion and unjustifiable advice.

In abdominal trauma, whatever the cause, we must not wait until there is muscular rigidity, vomiting and distention. We all know that when these symptoms are present operations succeed only by a miracle. In chronic abdominal disease the benefit of the doubt means conservatism. Study the case with care and deliberation. What you lose in time you gain in prognosis. In acute abdominal emergencies, especially the traumatic, the benefit of the doubt means radicalism. Make the diagnosis with speed and operate immediately. What you gain in time you gain in prognosis. I could give my personal experiences, which have forced me, rather against my natural tendencies, to become extremely radical in the presence of sudden and severe abdominal symptoms, whether traumatic or not. If the surgeon ever needs to be prompt in the application of operative measures for the relief of acute abdominal symptoms, he must be prompt when those symptoms follow violence to the abdominal wall.

ABSTRACT OF DISCUSSION

DR. GARRY D. HOUGH, New Bedford, Mass.: There is one diagnostic sign in cases of internal injuries of the abdomen which was not referred to by Dr. Sherk. It is not always present—perhaps in only 30, 40 or 50 per cent. of cases. When present, it tells you exactly where the trouble is located. That sign is the hyperalgesic zone, which corresponds to the injured viscus. In 1893, an Englishman first brought out the fact of a hyperalgesic zone corresponding to disease in an abdominal viscus. When this sign is present, so far as cumulative experience can yet tell us, it is an absolutely certain thing, but unfortunately it is present in only about half of the cases.

DR. MAURICE H. RICHARDSON, Boston: A most important point which is emphasized in this paper is abdominal diagnosis. In an abdominal case, the greater the difficulty of diagnosis the greater the interest, and the greater the satisfaction when exploration shows that diagnosis correct. Except in urgent cases, I take any amount of time necessary to come to a positive conclusion. But there is reason in all things. After violent blows on the abdomen, to wait for symptoms enough for a positive diagnosis is to let pass the only opportunity for successful intervention—so, too, in perforations of the alimentary canal, and in duodenal and gastric ulcer. On the other hand, it may save the patient an unnecessary exploration if the surgeon takes days, or even weeks, to make a diagnosis.

In teaching, I stand for extreme care in diagnosis, especially abdominal—for the exhausting of every symptom in the history, and of every sign in the physical examination, and for the education to the greatest nicety of the powers of observation and deduction, before subjecting a patient to even the slight risks of exploration. But when we come to abdominal emergencies we cannot wait. In large communities, where these acute emergencies are common, we cannot and do not wait for a positive diagnosis. We must feel assured that there is a reasonable certainty that some serious lesion demanding surgical remedy is present. The dangers of the exploratory operation are, of course, slight. I could pick out twenty-five men in this audience whose operations for chronic appendicitis

would number, in the aggregate, at least 50,000, with so small a mortality that it would be a negligible factor. And yet there is a certain risk which should be avoided in advising operation on inadequate study. When a surgeon advises a young girl to have the appendix taken out, and bases that advice on her saying that she has appendicitis, and on a physical examination which consists in leaning across his office table and pressing with his fingers on the right iliac fossa, through the clothing, corsets and all—I call that the extreme of absurd opinion and unjustifiable advice.

In abdominal trauma, whatever the cause, we must not wait until there is muscular rigidity, vomiting and distention. We all know that when these symptoms are present operations succeed only by a miracle. In chronic abdominal disease the benefit of the doubt means conservatism. Study the case with care and deliberation. What you lose in time you gain in prognosis. In acute abdominal emergencies, especially the traumatic, the benefit of the doubt means radicalism. Make the diagnosis with speed and operate immediately. What you gain in time you gain in prognosis. I could give my personal experiences, which have forced me, rather against my natural tendencies, to become extremely radical in the presence of sudden and severe abdominal symptoms, whether traumatic or not. If the surgeon ever needs to be prompt in the application of operative measures for the relief of acute abdominal symptoms, he must be prompt when those symptoms follow violence to the abdominal wall.

THE SECRET COMMISSION EVIL *

J. P. LORD, M.D.
OMAHA

There seems to me to be a greater need to discuss one of the ethical questions agitating the surgical world to-day, than to add another scientific paper. It has seemed to me that specialism, with all the advantages and benefits which it has brought to mankind, enabling specialists to render such distinct service to humanity, and thereby enhancing public confidence and esteem, has not been an unmixed blessing to the professional body. The new conditions, changed relations, variable rewards, and readjustments in the relationships of patient, family physician and specialist, together with new economic conditions, as developed by our numerous public and private hospitals, dispensaries, laboratories, corporation work, indemnity insurance, lodge and society practice, have brought problems for solution by the profession in general, and our specialty in particular. The commercial spirit, with which the present age is now credited, has added another factor, the control of which we, with our somewhat neglected code of ethics, have not kept. The rapid development of specialism, with its special rewards and the keen rivalry incident thereto, has developed a new order of things professional, the ethical adjustments of which have not yet been generally made.

There has been so much said on this subject that it would seem almost puerile to attempt to say more. Indeed, it is not my purpose to try to improve on what has already been so well and so fully presented. Realizing as I do that it is probably true that the practice of fee division, secret division, joint fees, commissions, so-called dichotomy, graft, and possibly obtaining money under false pretenses, is increasing, especially among the younger element, I undertake to arouse our members from their seeming lethargy. We teachers and hospital surgeons, as a rule, are established in our respective communities, and have not felt the force of this evil to so great a degree as to compel action. Those who follow will feel it keenly. Many young men are wrestling with this moral problem and will yield to the general trend of practice unless some aroused moral force within the profession, or the effect of publicity, checkmates this menace to professional honor, dignity and common honesty. I agree with those who favor publicity as the speediest and most effective remedy. Then, too, we need some Roosevelts to keep up a rapid-fire attack on this practice.

We should maintain a sentiment against any countenance of graft. Its devotees should not be given positions of honor. They should learn the penalty for unfair and unmanly competition. The present standards of membership of this society should prevail, and we would do well to revise our membership lists, since we have a considerable number who do business on a commercial basis. Our body is not in a position to reform the other fellows when we, too, are culpable. Scarcely a man among us is in a position to cast the first stone, but there are many who have recoiled from this thing on the discovery that this temptress had assailed their manhood and their integrity, and that they had actually violated their patients' confidences.

In writing on this subject several years ago I made the statement that the division of fees was not itself so bad as that to which it leads. The road is short and direct to the practice of graft. This may be a seemingly harsh term to apply to some of the more respectable forms of secret fee division. Secrecy, however, makes it dishonest and renders possible all forms of abuse. The results of the practice are so manifestly demoralizing as to cause all those who love their profession and cherish its sacred traditions, and who seek to uphold its honor and good name, to array themselves in opposition to those who seem concerned only for the monetary rewards of to-day.

It has been observed that those practitioners who work on a commercial basis are too prone to lose sight of the patient in their efforts better to serve their immediate selfish ends. Their lack of thorough conscientiousness leads them into questionable methods. They handle cases as merchandise instead of treating them as patients. This causes them to hold on too long before advising operation, and then to recommend operation on a moribund patient. Their zeal to have people operated on who are willing, causes them to work up cases, and this working-up process sometimes is so considerable that they claim compensation for it. The service is often times considered by them of monetary value equal to or greater than the skilled and experienced services rendered by the surgeon, who has possibly made or caused to be made various laboratory tests, and exhausted every resource to complete a diagnosis, and who has done the operating and given the after-care.

The specialists with their hospital connections and the valuable facilities for advanced and successful work, and the resulting wealthy and large clientele, cause the envious to consider that these men have the best of it, and they are willing to adopt grafting as their most ready means to easy money.

The practitioners who have for years adhered to an inelastic fee-bill find themselves with their financial wings clipped, and unable to rise above the level of customary fees. The specialist is somewhat of a law to himself and most often gets what he asks. These practitioners, therefore, avail themselves of the specialist's facile faculty of fee-getting, by requesting the specialist

---

* Read before the Western Surgical Association, Chicago, December, 1910.

to add a sum for them, as the people would object to paying them a proper amount.

The specialists have often been accommodating in this way, and have saved themselves and the family physician the trouble of explaining the matter to the patient. The country doctor often plays "goody-goody," and says that he will not make a charge for accompanying the case if expenses are paid, of course depending on receiving a part of the specialist's fee. The specialist's fee is, therefore, under such circumstances, unnecessarily large. This gives the patient and all his friends an exaggerated idea of the value of the surgeon's services, and the relatively greater importance of the work of the specialist. The poor country doctor's services, therefore, become diminutive, judged by the cheapness of his fees. In other words, he is overshadowed and has cheapened himself.

Physicians of all classes must learn to make charges commensurate with the value of their services. Fee-bills hinder in this. The fee-bill is the union scale. It bolsters up the incompetent and often prevents the high-class, scientific man from getting his deserts. A hidebound fee-bill and an increasing lack of appreciation of the practitioner's value, dwarf him, and compel him to resort to questionable methods for playing even. He must learn to elevate his standing by special fees for his improved methods of diagnosis and treatment. These have been acquired, perhaps, by special post-graduate courses, time abroad, and special equipment, and yet his price per visit or consultation is the same as it was twenty-five years ago.

Surgeon's fees may be no greater, but when we come to consider that it is possible for the surgeon to operate on several patients in the course of one morning, which is rendered possible by having the command of an unlimited hospital force, we can readily understand how the net results may be much greater than in the earlier days of surgery. On the other hand, the practitioner finds his work more exacting and painstaking, requiring more time, trouble and expense.

The rapid development of surgery during the last quarter century, with its greater rewards, has attracted so many to its ranks that competition for business has become so keen as to bring about these trade methods. Too many are now occupying the surgical field to be favored with teaching and hospital positions. Therefore, other means must be resorted to for attracting business. This custom of fee division, however, was probably established by some of the very men holding these places, and now their old weapon is turned against them.

Many of our surgeons throughout the country are ready-made after a few weeks at some of our large clinics, and then after self-styling themselves as surgeons and passing word along the line that they are liberal and fair with the general practitioner, they are soon doing business and are not embarrassed by that period of waiting so well remembered by some of us.

Our medical schools have been remiss in their ethical instruction to students. The subject of fee division has been eschewed in some faculties for fear of engendering feeling, developing strife and endangering the integrity of the organization. The same silence has prevailed in medical societies, because it might cost something to speak. Students are now without the close contact that was enjoyed in the days of the preceptor, whereas they now need more of the moral and ethical side than ever before.

Clearly so gross a violation of honesty and ethics, if continued, will lead to greater violations of fair play. If our tendency is to lower levels of conduct, it will be but a question of time until our noble profession will be out of favor with the people. There has never been a time when full confidence is more needed, because the cooperation and confidence of the people is necessary to secure the legislation needed for conserving the public health. This would aid the people in realizing our dreams of health and resultant happiness from the prevention of disease consequent on a universal crusade against violations of hygiene and health, and for the elimination of all preventable disease. A mercenary profession unworthy of public confidence will retard this movement and the unworthy members must be held to account by us and our standards maintained. A present the profession is becoming demoralized and our standards are being systematically assailed. Not only our standards, but those who stand for them, are attacked and their characters and motives are besmirched.

The graft element is going into medical politics and some county societies are controlled by this element The old guard is discredited and lowered standards set up. The influence of these classes is against the American Medical Association, and their influence is soon to be felt in their organized opposition. The profession of Chicago and some other places do not have to go from home to read the handwriting on the wall.

The demoralization will be more complete when this practice extends to other lines than surgery. The movement has begun, and consultation practice and other specialties are now in the throes of this evil. The practitioner will call a man of sufficient standing to enable him to name a fancy price as the consultant's fee, which he collects and then remits the consultant the minimum fee. Any one of us can verify this by personal experience.

The primary object of fee-splitting is to get business It is unfair competition. It has been my observation that fee-splitters are bad competitors in other ways They will resort to other equally devious or questionable means of getting patients. They are usually underbidders; they lack sincerity; they are dishonest; they do not stop at dividing with physicians; hotel clerks hack-men, news-agents, bar-keepers, ordinary clerks traveling men, medical students, priests and preachers—all are represented, though few of the latter classes stoop to this practice. Those who do this will not sto at wilful *misrepresentation of men of high characte* and standing. Physicians go lower and lower wh become infected with this vice, and their penchant fo easy money becomes their undoing. Their method become known in a community. Then they sell out move to another locality, and immediately proceed t repeat their previous methods. These, of course, ar exaggerated examples of the grafter, but a physician who grafts at all is not only unethical but also dishonest

The graft spirit has developed alarmingly within decade, but a reaction has set in. Encouraging report of progress have come from Chicago, Minneapolis and St. Paul, and I am pleased to report that a stand ha been taken by the faculty of the University of Nebrask and of the Creighton Medical College. Whole state are, however, reported in the grasp of the system. Kansas, Iowa and Missouri, as well as many other states are affected by it. From Kansas specialists report tha division of fees is too mild a term; that the surgeo must now accept what the general practitioner is willing to give him.

Hospital service is now required for graduation by some medical colleges, and considerable numbers who have had hospital training and are qualified to do surgery go to our smaller cities and larger towns. To gain a foothold, notwithstanding the prestige of college professors and the large denominational city hospitals to meet competition, a resort to fee division and ultimate graft is the easiest course. The wail is going up in every quarter from our less enterprising but more conscientious confrères, and we are now hearing from some of our city brethren, who are beginning to observe the rather alarming prevalence of these methods of finance, exploitation of cases, and the merchandising of patients.

After all of this lugubrious, pessimistic and despairing talk of conditions in our profession I am still hopeful. Physicians as a class are the best people on earth, made so by their education, environment, every-day training in charity and human sympathy.

This evil thing had a very innocent and insidious start. The surgeon wanted to be fair and divided fees that the physician had in part actually earned. Nobody was harmed, for the patient had not been wronged. This seemed innocent enough. Then came the time when the physician collected the fee and told the surgeon that the patient could pay nothing, or could pay but little, and either kept the whole or an undue portion, or took the divided fee and then rendered a separate bill. After this he became money-mad and sought subjects on which to satiate his sordid desires for easy gain. If the honest surgeon turned him down he sought those who would not and he has been busy ever since.

The surgeon who follows the lines of least resistance in these moral matters soon finds himself in the grasp of the system. Many very good, but quasi-respectable, men follow this practice, persuading themselves that the doctor cannot be paid too much, and uphold the practice because it suits their convenience and is more profitable. Then, too, they say, "What's the difference?" The difference is most keenly realized when you have to tell your son, as I have mine, that our profession is becoming commercialized.

The prospects, therefore, are not encouraging for the profession, and we are compelled to admit that it is not what it once was. Its ideals are lowered. Its ethics may not be maintained and the best men under these conditions will not be eager to enter it.

Such courses, if pursued, will cost the profession its influence, cause loss of respect and confidence on the part of the people. Overcrowding and commercial competition will cheapen services and with the increase of endowed hospitals, dispensaries and laboratories, rewards for scientific medicine will be reduced. The general profession, which is already overshadowed by specialism will then be in hard lines. Every time a physician fails to make a proper and independent, self-respecting charge for the services rendered by him in the making of a diagnosis, recommending an operation, accompanying a patient to a hospital, being present, or assisting in an operation, he belittles himself, unduly aggrandizes the surgeon and discounts his own future usefulness, making it that much harder for those who follow him.

To be respected the physician must be self-respecting and respectable. He is the surgeon's friend and the surgeon will help him, if he wishes, to be independently, adequately, and respectably paid for his valuable services to the patient and to the surgeon as well. Division of fees is wrong, dishonest, and must be stopped for the good of all concerned. It has been my settled conviction for a long time that the physician is the ultimate loser by this practice, no matter how immediately profitable it may be to him. He is becoming dwarfed by his own short-sightedness and asphyxiated by a noose which was cast about him by a crafty specialist, perhaps, but which he himself is now tightening about his own throat.

There has been more harm done than can be overcome in a generation. Delayed action means more sacrifice. The organized profession should busy itself in reformation and take its stand in medical colleges, hospitals, and societies, and as individuals and organizations, educate the public and reform our own members. The most hopeful view may be taken of the result. Any practice which even smacks of graft, or of obtaining money under false pretenses, cannot endure before a righteous public opinion. Nor will it continue in a profession which has cherished ideals from Hippocrates and the whole line of medical saints, religiously followed by the vast majority, during all the ages of the history of medicine.

THE TREATMENT OF ANTEFLEXION OF THE UTERUS*

HENRY T. BYFORD, M.D.
CHICAGO

I have nothing new to offer in the treatment of anteflexion of the uterus, except the resolution not to offer anything new. The great and original Solomon knew of nothing new. In surgery most of the new things are nuisances because it takes so much writing of papers and mutilation of patients to demonstrate that the new usually eventuates in nothing, and should not be written about.

My experience with anteflexion is that somehow or other we have always been able to relieve our patients. Yet, judging from the new things that have been advocated from decade to decade, one would infer that up to the present time, or at least up to the last new thing that is offered for trial, the real thing had not been discovered. It is "off" with the old and on with the new." There are many great operators, yet few great surgeons. The fact is that those who make real advances in surgery, as in other arts, do not look into the future but into the past. They take the good they find in old things and adapt it to the needs of the present, and thus advance our knowledge by giving us, not something new, but only the appearance of something new. But I am not going to offer even the appearance of something new. I am content, with Solomon, not to pretend to know anything new.

Instead therefore of looking toward the future which, until it comes, can have nothing reliable to teach us, let us review what the past has taught us. In mild cases of anteflexion with dysmenorrhea and sterility a few moderate dilatations by the sound have been followed by pregnancy and cure. In other cases divulsion and temporary packing of the cervix have sufficed. But we have not infrequently encountered cases in which congenital and developmental deficiencies were such that these methods only temporarily relieved the dysmenorrhea, and the sterility not at all. In some of them the monthly crises have led to hyperplasia of the uterus and ovaries and chronic invalidism, and last, but not least, to a loss of the ovaries by operation. The uterine body is apt to be well developed, or to become so as the result of the excessive monthly hyperemia connected with its distention by the menstrual fluid and its efforts at expulsion; but in the cases of which I am speaking, the uterine ligaments remain short, the cervix and vaginal fornices poorly developed, and more or less pressure atrophy of the anterior cervical wall takes place.

---

* Read at the twenty-third meeting of the Southern Surgical and Gynecological Association, Dec. 13, 1910.

A few dilatations with sounds, or divulsion and packing, unless followed by pregnancy, cannot rectify the last-mentioned conditions. Discission of the cervix, whether by the Simpson or Sims methods, or by the Dudley or Pozzi modifications, does not rectify them. These operations often cure the dysmenorrhea and establish uterine drainage, but they mutilate and tend to throw the cervix out of function, and thus favor atrophy rather than development. The relief from suffering is frequently, although not always, immediate, yet in quite a proportion of cases is not permanent. When it is permanent the mutilation is apt to be such that the uterus cannot retain the fecundated ovum. In short, such operations benefit the surgeon rather than the patient or posterity.

What is lacking in all of these procedures is the development of the cervix and vaginal vaults. The uterine cavity is not even made straight; its lower or cervical portion is destroyed, and thus a portion of the curve eliminated. But anteflexion is normal, and the cavity of the uterus does not have to be made straight. The entire uterine cavity can be made large enough to allow of a normal outflow of the secretions without destroying the lower or cervical portion. Such a condition we sometimes observe in multiparæ with extreme anteflexion. And just as we can obtain this result temporarily by an adequate dilatation, so we can secure it permanently by keeping the cavity adequately dilated. But there is only one way of keeping it dilated and that is by developing the cervix. Pregnancy does this and takes months to do it. We can also do it, but we must also take months, many months. Goodell tried to do it by the extent of the dilatation. Gill Wylie succeeded by a persistent use of a stem after the divulsion, and Davenport still uses the stem method quite successfully. The Outerbridge stem has, I think, been successfully used, but it is not a safe instrument. Vulliet kept the uterus packed with cotton balls for variable lengths of time with success. Experience and reason have taught us that almost any foreign body that cannot be accommodated in the uterine cavity without some enlargement or stretching of that cavity, will, if kept in it, cause some development of the uterus and its cavity in size. If the foreign body project down into the cervical cavity it will act similarly on the cervix. But any foreign body left in the uterus is liable to cause abrasions and infection, and, with the supervision that can ordinarily be given, invites disaster.

Since none of these methods has found general favor, and it is no longer considered an evidence of fogyism not to perform a radical operation, I shall venture to present the claims of the method I have always employed. It consists in introducing a body large enough to overdilate the cervix, and often enough to keep it overdilated. I have treated puerile cervices on this principle and feel that I am very far within bounds in saying that if we can keep the entire cervix dilated sufficiently for the passage through it of a number 20 (Am. scale) male urethral sound from one to two years the cervix will then continue to functionate normally. And this treatment is not so strenuous and tedious as the words "two years" would suggest.

Without the recital of individual cases I will say in a general way, that I have sometimes commenced by dilating biweekly with a small block-tin sound and have progressively dilated to about the size indicated. I have then maintained it by means of weekly dilatations for a time, then bimonthly, then monthly until the year was up. As a rule I have had the patients come back in six months or a year for a few weekly dilatations in order to be sure of permanency of results. In most cases I have preferred beginning with divulsion under general anesthesia and have then prevented contraction by the periodical passage of the sound. But the important and indispensable part of the treatment is its continuance for many months. In the event of a return of the dysmenorrhea an immediate resort to the treatment gives prompt relief. A few biweekly dilatations followed by a few monthly ones usually suffice to render the cure permanent.

The greatest objection to the treatment is that it is painful. I reduce this objection somewhat by passing the sound frequently at first, *i. e.*, by not giving the cervix time to contract too firmly between times. As the tendency to rapid, firm contraction diminishes, the dilatations can be made at longer intervals without increase of pain. I like, however, to dilate as widely each time as the patient will tolerate because the greater each dilatation and stimulation the greater the effect on development. As I have already said the tedium of the treatment is not as great as one might suppose, because, after the dilatations are a month apart, they occupy but little of the patient's time and attention, and can then be continued as long as desirable. The temporary pain of one or two treatments each month is more easily and willingly borne than the monthly dysmenorrhea, the more so as the patient knows that they will soon become less frequent. The pain ceases the moment the sound is withdrawn, and the patient may go out from the office to do her shopping.

With regard to the technic, the patient takes a copious normal salt douche before leaving home for the office. After the introduction and adjustment of a sterile bivalve speculum, the vaginal fornices and cervix are swabbed out thoroughly with a 5 per cent. solution of phenol, and the sound, after having been curved to suit the case, is dipped into the same solution immediately before being passed. Sometimes it is necessary to steady the cervix with vulsellum forceps, but the vaginal fornices are often so small that the expanded speculum puts them on the stretch and keeps the cervix from receding too far. Before removing the speculum I disinfect the uterine cavity, and introduce a dry sterile wool tampon under the cervix and leave the latter for twelve or twenty-four hours for its dilating effect on the vaginal fornices. The patient withdraws it by means of an attached thread and uses a copious normal salt vaginal douche.

I have thought it worth while to go into the details of this old, well-known treatment for the following reasons:

1. I know of no book or monograph in which its efficacy is given proper appreciation.

2. I know of none in which the necessity of such persistence in overdilatation is sufficiently emphasized.

3. I know of no method that will give better results if persisted in to the extent I have recommended.

4. I know of no cure that is as safe in the hands of the average practitioner.

5. I know of no book in which a sufficiently definite detailed technic is given.

6. The cutting methods are all objectionable and irrational in cases of arrested development.

I might add that, in patients who are hyperesthetic or intolerant of pain, this treatment can be combined with other treatment. For instance, if the patient will not allow a sound of the same size to be passed each time, and the cervix gradually contracts, divulsion under anesthesia can be performed two or three or four times at intervals of two or three or four months and the dilatation kept approximately at the same degree by the sound between times.

100 State Street.

THE IMPORTANCE OF THE AUTOPSY AND OTHER PATHOLOGIC-ANATOMIC EXAMINATIONS[*]

HANS CHIARI, M.D.
Professor of Pathology, University of Strasburg
STRASBURG, GERMANY

In 1761 Giovanni Battista Morgagni (1682-1771, Professor of Anatomy in Padua) published his famous work: "De Sedibus et Causis Morborum per Anatomen Indagatis," and thereby became the real founder of human pathology. He attempted to give a very complete picture of morbid processes by carefully comparing the clinical aspects of disease with the anatomic findings in a large number of cases. In the title of his work Morgagni summed up the chief problems of pathologic anatomy and in recognition of this fact Rokitansky (1844-1875 professor of pathology in Vienna) used the title in the following somewhat modified form, for the inscription on the pathologic-anatomic institute in Vienna: "Sedibus et Causis Morborum per Anatomen Indagandis."

As the sphere of pathologic anatomy has broadened since it became an independent science seeking to solve its own problems, not only by the examination of the cadaver, but also in other ways, for instance, by the experimental method, the position of the pathologist has correspondingly increased in importance. In the autopsy room the pathologist must take due cognizance of the ever-broadening and more exacting demands of the clinician; he must endeavor at each autopsy to give the physician a satisfactory explanation, and he must examine each case most minutely with the aid of modern methods of histology and bacteriology. By means of such elucidation, he will materially assist the clinician, and he will also develop new ideas in his own scientific field. In this way he can advance toward the goal of all the medical sciences, namely, the relief of human suffering.

Therefore there can be no doubt of the need of pathologic investigation. All the medical schools and hospitals are wise in striving for a large amount of autopsy material in order that the students may be instructed, that physicians may gain experience, and that the interests of science may be advanced. Naturally the autopsies must all be done with the strictest adherence to the principles of humanity, with careful consideration for the wishes of the relatives, and with the greatest precautions to avoid any mutilation of the body. To this end pathology has at its disposal a well-developed technic which is constantly being improved.

In order to give a graphic picture of the importance of post-mortem examinations, I should like to select a series of cases from the eighty-seven autopsies performed at the Pathological Institute in Strasburg during the month of June, 1910, and to discuss them somewhat in detail:

ILLUSTRATIVE CASES: CLINICAL AND PATHOLOGIC-ANATOMIC DIAGNOSIS

Eleven cases of fatal nutritional disturbances in infants between the ages of 2 and 6 months: six cases of enteritis; five cases of general atrophy.

Two cases of status lymphaticus:

Patient, male, aged 16. Otitis media with meningitis and chronic general tuberculosis. Death while under chloroform narcosis at the beginning of the operation.

Patient, female, aged 27. Ruptured tubal pregnancy in second month. Salpingectomy seven hours after rupture. Death three and one-half hours later. Moderate anemia.

Four cases of fatal embolism of the pulmonary artery:

Patient, female, aged 38. Death from thrombosis of the right femoral vein, four days after salpingectomy for gonorrheal salpingitis.

Patient, female, aged 53. Death from thrombosis of the ovarian vein of the left side, six days after double ovariotomy for carcinoma.

Patient, female, aged 58. Death from thrombosis of the left external saphenous vein, six days after operation for femoral hernia.

Patient, female, aged 63. Death from thrombosis of the right external saphenous vein, twenty-two days after encephalomalacia.

Two cases of auto-intoxication from incarcerated hernia:

Patient, male, aged 73. Incarcerated inguinal hernia for five days. Death one day after operation for hernia. Epithelial necrosis of the kidneys.

Patient, female, aged 58. Incarcerated femoral hernia for four days. Death three days after operation for hernia.

Two cases of latent septicemia:

Patient, female, aged 40. Clinical diagnosis: ileus from carcinoma of the sigmoid flexure. Pathologic-anatomic diagnosis: streptomycotic peritonitis caused by suppurative salpingitis.

Patient, female, aged 56. Clinical diagnosis: chloroform narcosis after hysterectomy for ulcerating carcinoma of the cervix. Death one day later. Pathologic-anatomic diagnosis: streptomycotic septicemia.

Two cases of birth injuries:

Fetus of 9 months. Breach extraction. Compression of skull and rupture of the spinal column between the fifth and sixth dorsal vertebræ.

Patient, female, aged 25. Transverse position. Laceration of the vagina following attempted version outside of the hospital.

One case of criminal abortion:

Patient, female, aged 24. Pyemia after abortion. Laceration of the vagina, posterior labium of the external os and of the cervix.

One case of injury due to enema:

Patient, female, aged 38. Peritonitis from perforation of the rectum.

Two cases of latent carcinoma of the stomach:

Patient, male, aged 43. Clinical diagnosis: carcinoma of the sigmoid flexure. Pathologic-anatomic diagnosis: carcinoma of the pylorus and secondary carcinoma of the peritoneum, with stricture of the sigmoid and of the descending colon.

Patient, female, aged 27. Clinical diagnosis: carcinoma of the ovaries. Pathologic-anatomic diagnosis: carcinoma of the posterior gastric wall and secondary carcinoma of the ovaries.

---

[*] Address delivered before the Harvey Society, New York, October 15, 1910.

One case of latent pericarditis:

Patient, female, aged 71. Clinical diagnosis: lobular pneumonia. Pathologic-anatomic diagnosis: lobular pneumonia, tuberculous pericarditis with effusion, latent tuberculosis of the apex of the lung.

One case of late recurrence of carcinoma:

Patient, male, aged 47. Recurrence of carcinoma in the cicatrix four years after excision of the carcinomatous rectum.

One case of puerperal eclampsia:

Patient, female, aged 37. Multiple necrosis of the liver.

One case of Hodgkin's disease:

Patient, male, aged 27. Swelling of the left lymphatic glands and left tonsil. Nodes in the spleen, lungs and pleuræ. (The same diagnosis was made nine months previously from an extirpated axillary gland.)

One case of nephrolithiasis:

Patient, female, aged 67. Right hydronephrosis and uratic calculi. Left uratic nephrolithiasis. (Calculi in left kidney stained with methylene blue.)

COMMENT

The cases of nutritional disturbances in infants confirm the frequently expressed opinion that serious digestive disturbances occur without even microscopic changes in the intestines, which depend entirely on chemical alterations in the intestinal contents. These chemical changes are being carefully studied of late by pediatrists and thereby a real basis for a correct therapy is being established.

The cases of status lymphaticus show the great significance of this constitutional anomaly. Patients of this class stand chloroform anesthesia and loss of blood very poorly.

The four cases of fatal embolism of the pulmonary artery are good illustrations of the frequency of this lesion, which so often interferes with the success of operations. Such an embolism is not a rare occurrence, and it is easy to realize that surgeons take every precaution to avoid such a complication. This condition cannot always be diagnosed clinically with certainty, and therefore the autopsy is necessary to confirm the diagnosis.

The cases of incarcerated hernia serve to show how much danger attends the retention of the intestinal contents. Very commonly this decomposition of the intestinal contents causes an auto-intoxication to which the patients succumb in spite of a successfully performed herniotomy. In order to prove this point of view, I have but to refer to the first of the two cases in which the microscope showed diffuse necrosis of the renal epithelium. In other cases, on the contrary, the necrosis of the liver parenchyma is of special interest.

The two cases of septicemia emphasize the importance of bacteriologic examinations at the post-mortem table. In the first case, no positive clinical diagnosis could be made. The autopsy showed a streptococcic peritonitis due to a purulent streptococcic salpingitis, which in turn, judging from the nature of the bacteria, was of puerperal origin. In the second case, streptococci were cultivated from the heart's blood and from the various tissues of the body, and the case therefore had to be diagnosed as a streptococcus septicemia. Later, on talking the matter over, the clinician thought, and rightly, I believe, that the infection was due to the deep ulceration of the carcinoma of the cervix, which had been curetted.

The cases of birth injuries are of great importance because they can easily result in severe injury to mother and child. In the first case, the delivery was certainly difficult, and in spite of the fact that it was performed by a very competent obstetrician, it resulted in a fracture of the spinal column. In the second case, a physician not in the hospital had made several attempts to correct a complex presentation by means of version and had thereby lacerated the vagina so severely that there remained only a strip of its anterior wall behind the urethra. The patient was subsequently brought to the hospital and died of acute anemia.

The case of criminal abortion shows the typical lesions which we find in this class of cases. Frequently there occur punctured wounds of the posterior wall of the vagina, perforations of the cul-de-sac of Douglas, injuries of the posterior lip of the cervix and of the adjoining portion of the uterus. As these injuries are for the most part done with unclean instruments, the women so treated are very often victims of fatal puerperal infections.

The case of injury due to enema, which happened to a 38-year-old woman outside of the hospital, may serve as a warning. Pathologic anatomy teaches that such injuries from enemas are due to the use of hard cannulas, and are, especially in children, much more frequent than is generally believed.

The cases of latent carcinoma of the stomach are very important from a diagnostic point of view. In the first case, the secondary carcinoma of the peritoneum, which had invaded the sigmoid flexure and caused a stricture, was diagnosed as a primary lesion, and in the second case we were dealing with a condition frequently described of late, a primary carcinoma of the stomach with typical secondary implantation lesions in both ovaries in which the secondary metastases had been regarded as primary lesions.

In the same way, the case of latent pericarditis demonstrates the difficulty of many a clinical diagnosis.

The case of recurrent carcinoma in the scar four years after extirpation of the rectum for carcinoma, is instructive because this recurrence was a very late one. We now have, however, definite knowledge of much later relapses.

The case of puerperal eclampsia was typical. It showed perfectly the characteristic areas of necrosis and hemorrhage of the liver, which were first described by Schmorl.

In the case of Hodgkin's disease there was found the well-known histologic condition of granulation tissue with fibrous connective tissue and polynuclear giant cells in all the diseased areas; these lesions had also been found in the axillary glands, which had previously been extirpated for diagnostic purposes.

The last case had the significance of an experiment. The 67-year-old woman had been given methylene blue on account of symptoms of cystitis. At the autopsy the uratic calculi in the left kidney, which secreted urine, were stained with methylene blue, whereas those in the right kidney, which had ceased to functionate as a result of atrophy following hydronephrosis, were entirely free from any stain.

These cases, selected from the records of one month, well demonstrate the importance of the careful routine autopsy and indicate how much the student and physician can learn both from a scientific aspect and from the point of view of the welfare of the patient. Every autopsy adds to our store of knowledge and justifies the old adage which we often see inscribed in the autopsy room: "Hic est locus ubi mors gaudet succurrere vitæ."

A pathologic institute can be of service to the physician and of benefit to the sick in other ways. I refer to the microscopic diagnosis of tissue removed by the surgeon. I may here mention the results of the microscopic examination of curettings from the uterus. How often the examination does not determine whether we are dealing with an abortion, an endometritis or a carcinoma!

Furthermore, I may refer to the microscopic examinations for carcinoma of excised tissue, a recourse which so often saves the patient from the sacrifice of important organs, e. g., the tongue, the larynx, the penis, the cervix. On the other hand, if the carcinoma or other neoplasm is diagnosed, it may lead to an immediate life-saving operation. Finally, I wish to emphasize the importance of a careful examination of excised tumors, for this not infrequently, to the gratification of the pathologist, demonstrates that a condition which has been considered malign is in reality benign and permits of a favorable prognosis. These investigations are indeed very difficult and the pathologist cannot be too careful in his reports; otherwise there is danger that he will bring undeserved discredit on the value of diagnoses made from excised tissue. He must never hesitate to acknowledge that he is unable to render a definite diagnosis. Then he will rightly fulfil his duty and the clinician will appreciate the weight of his opinions.

Thus it is seen how important is the function of the pathologist in performing autopsies, and how his calling is not only didactic but humanitarian. His work, therefore, deserves support and encouragement from all sides, and especially from the laity. The public must be made to appreciate to an ever-increasing extent the importance of pathologic anatomy. That this hope may soon be realized is my earnest wish, especially for the American universities.

A METHOD OF TREATING THE PROSTATIC UTRICLE *

J. T. GERAGHTY, M.D.

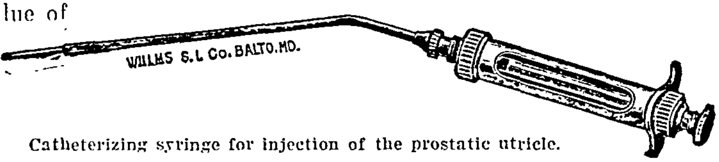
Associate in Genito-Urinary Surgery, Johns Hopkins Hospital
BALTIMORE

Urethroscopy of the posterior urethra has been comparatively slow in developing, and not until the last few years has sufficient attention been directed to this important field. One result of this increased study has been the recognition of the important part which diseases of the verumontanum play in the production of severe and often distressing symptoms, generally classed as prostatic neuroses. In the milder cases remedial results were obtained by massage of the prostate, dilatations, instillations, etc. In others only temporary relief could be obtained by these measures, while in the aggravated cases frequently no amelioration was obtained.

Wossidlo was the first to call attention to the manifold symptoms which resulted from inflamed conditions of the verumontanum. He found that various symptoms usually ascribed to chronic prostatitis were not infrequently encountered in individuals in whom no prostatitis could be demonstrated. Sexual disorders such as precocious ejaculation, painful ejaculation, frequent seminal emissions, neuralgic pains in the perineum, groin and testicles, suprapubic region, sciatic pains, backache, etc., were associated commonly with the pathologic condition of the verumontanum. In the milder cases he recommended painting with tincture of iodin; in the severe cases he employed 10 to 20 per cent. silver nitrate or even a caustic stick, making direct applications through the urethroscope.

Young, for a considerable time, has practiced curettage of the verumontanum, following this by direct application of a pure stick of nitrate of silver.

The edematous condition of the verumontanum in many cases, with a normal appearance of the mucous membrane covering it, and the frequency with which one finds the orifice of the utricle intensely red and congested, suggested that in many of these cases the seat of the trouble lay in the utricle itself. In normal cases the verumontanum is seen through the open urethroscopic tube as a small, rather rounded, elevation; the mucous membrane covering it is distinctly pale and in marked contrast to the rather deep red of the surrounding urethral mucosa. In the midline and directly anterior, in the majority of the cases, can be seen the orifice of the prostatic utricle. The shape and size of the orifice varies; in some it appears as a minute, rounded depression, in others the orifice is a distinct slit, occasionally several millimeters in length. The ejaculatory ducts are usually not visible, but are situated laterally and generally lower on the wall of the verumontanum than the opening of the utricle. The cavity of the utricle varies some in size and shape. In most cases it is 0.5 to 1 cm. long. It may, however, be several centimeters long and extend up beneath the urethra as far as the bladder. I have found that the capacity of the utricle varies from 5 to 10 minims in the average case, but in an exceptional case it may be as much as 30 minims.



Catheterizing syringe for injection of the prostatic utricle.

The utricle is to be considered as a rudimentary organ representing the terminal portion of the Müllerian ducts, and for this reason it has been called the *male* uterus, although it is more correctly the analogue of the vagina.

It seems very probable that the utricle, on account of its size, can readily be the lurking-place for infection and as a result of the diseased condition in this cavity give rise to the pathologic picture so frequently seen in the diseased verumontanum. Although the literature is replete with references to the inflamed appearance of the utricular orifice, and numerous observations of pus exuding from the utricle have been made, no practical method of treating this sinus has, so far as I am aware, been suggested. The ease with which the orifice of the utricle can be observed in most cases, and the considerable size of the outlet, suggested the possibility of catheterizing through a straight urethroscopic tube and making injections directly into the cavity. By means of a syringe, shown in the figure, it has been found not only feasible, but surprisingly simple, to make injections directly into the utricular cavity.

Technic: A straight Number 24 (French) urethroscopic tube with an external light is passed into the prostatic urethra beyond the verumontanum. Introduction of the straight tube to this point is practically always readily performed without the production of any trauma. The introduction of the tube beyond this point in occasional cases is accomplished with some difficulty, owing to the rather acute ascent of the posterior part of the prostatic urethra to the vesical orifice. When the tube, after passing some distance through the prostatic urethra, encounters resistance, one is practically always beyond the verumontanum. On moving the obturator one readily recognizes from the Y-shape of the urethral orifice that the end of the tube lies towards the vesical end of the verumontanum. The tube is then gradually withdrawn until the readily recognized verumontanum bobs into view. The tube is withdrawn until the anterior face of the verumontanum projects into the open portion of the tube. The mucous membrane is carefully and gently sponged with cotton swabs. The above position of the tube causes a tilting forward of the verumontanum so that the utricular orifice, which lies rather on the upper surface, comes directly facing the open end of the tube. The tip of the syringe can now be readily introduced into the orifice of the utricle, the contents of the utricle aspirated for microscopic examination, and injection readily made into its cavity. Not infrequently, owing to the edematous condition of the mucous membrane, the utricular orifice is not visible, but with gentle probing with the tip of the syringe in the middle towards the upper surface one will rarely have difficulty in accomplishing catheterization.

---

* From the genito-urinary clinic of the Johns Hopkins Hospital.

Silver nitrate has been the drug employed almost entirely, and it seems to give the most satisfactory results. While one can employ for external applications to the verumontanum silver nitrate in very concentrated solution, or the actual caustic, without the production, as a rule, of severe reactions, these strong injections are not well tolerated when given into the utricle. In patients with numerous neuralgic pains, the result of utricular disease, it is well to begin with injections of 1 per cent. and gradually increase the strength to 2 or 3 per cent. The employment of too strong a solution may cause intense pain lasting over several days. The injection should be given slowly, as forcible distention may be quite painful.

The reaction produced by too strong injections frequently reproduces in a striking manner the different neuralgic pains of which the patient has complained. When 1 to 3 per cent. solutions of silver nitrate are employed the injections may be repeated at intervals of from five to seven days, but when stronger injections are employed they should not be repeated more frequently than every two to three weeks.

Painful ejaculation, according to Wossidlo, is due to a sclerosed condition of the lower end of the ejaculatory ducts leading to more or less contracture. The forceful emptying of the seminal fluid through these narrowed inflamed ducts produces the pain which occurs, and in many cases the pain is so severe that the patient is forced to refrain from coitus. It seems probable, however, on account of the frequency with which one or both of the ejaculatory ducts open on the floor of the prostatic utricle, that when the seminal fluid is thrown into this cavity the sudden distention of the inflamed utricular wall may produce the sudden sharp pain occurring at the moment of ejaculation.

Hematospermia, which is seen in the absence of disease of the seminal vesicles, may result from congestion of the utricular wall. In one case of hematospermia aspiration of the utricular contents showed a considerable amount of bloody fluid.

The benefits ascribed to irrigation and injection of the vasa deferentia by some authors are probably explained in many cases by the flushing out of the prostatic utricle, which occurs owing to the fact of the ejaculatory ducts opening so commonly on the floor of the utricle. The good effects in these cases cannot result from the washing out of the seminal vesicles, as it is questionable whether the fluid injected into the vas finds its way to any extent into the cavity of the seminal vesicles, owing to their anatomic structure.

Dribbling of urine following the act of urination I have seen in many cases without any explainable cause. No stricture, sclerosed condition of the posterior urethra, pathologic conditions of the prostate or spinal cord trouble, could be demonstrated. In many cases observed, the dribbling has been a great annoyance to the patient and rebellious in responding to the usual forms of treatment. In four such cases in whom no improvement was obtained, as a result of dilatations electric applications, massage, etc., the dribbling has been entirely relieved by applications to the verumontanum and utricle injections. In two of these cases only slight improvement followed treatment of the verumontanum, but they responded rapidly and promptly to treatment of the utricle. The explanation of this does not seem clear. Infection of the utricle not infrequently is the cause of persistent recurring posterior urethritis. One case of persistent posterior urethritis, due to the colon bacillus, which had resisted during several years all efforts to dislodge the infection, on careful urethroscopy of the posterior urethra, showed pus oozing from the prostatic utricle. Injections of 1 to 2 per cent. silver nitrate into the utricle was very soon followed by a complete disappearance of the infection. Another patient with persistent posterior gonorrheal urethritis, who had been under treatment many months, was finally cured by the same procedure Infection in the prostatic utricle is probably the cause of many cases resistant to ordinary forms of treatment In some cases, particularly when the orifice of the utricle is small, it is well to snip out a wedge-shaped piece of the utricular roof, thus affording better drainage. This can be done by means of scissors devised by Young for excision of portions of the verumontanum.

AN IMPROVED GRAVITY APPARATUS FOR THE INTRAVENOUS INJECTION OF SALVARSAN

JOSEPH L. BOEHM, M.D.
ST. LOUIS

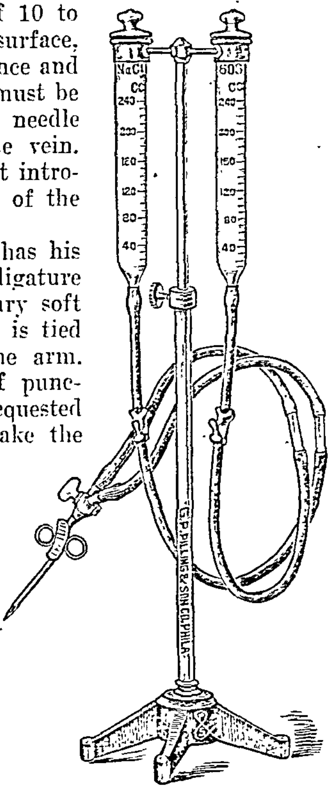
My improved gravity apparatus for the intravenou injection of salvarsan seems to overcome and solve many of the difficulties which, as reports have shown, are connected with this method. The aim is to avoid getting any of the solution into the subcutaneous tissues befor the needle enters the lumen of the vein. The severa syringes and forms of air-pressure apparatus already on the market have proved far from satisfactory, and leav much to be desired in the way of a perfect technic. My apparatus is portable, can be disconnected in all part of the stand, and by a thumb-screw allows of lowering and elevating the containers to any desired level, so a to control the rapidity of the flow of the solution into the vein. No solution which is not absolutely clear and sterile should be introduced into a vein. Clearness i to be obtained only by filtration through sterile filter paper. In my experience very commonly the salvarsan solution contains some foreign flocculent particles; and there is also danger of small particles of glass being chipped off, if glass beads are used in the mixing cylinder; even if a mortar and pestle are used to triturate the salvarsan, such flocculency commonly exists

Two graduated glass containers of 250 c.c. capacity are used. Into one is poured 150 to 200 c.c. of sterile salvarsan solution. The other is filled with a like volume of sterile saline solution (made with sterile distilled water and chemically pure sodium chlorid).

The saline solution is allowed to flow out of the needle so as to expel all air from the tube. The stop-cock is now reversed, allowing the salvarsan solution to flow out of the needle, thereby expelling all air from its respective tubing. The stop-cock is now reversed to its former position, until the saline solution is running in a slow even stream from the needle. The desired site of puncture is selected on the arm or at the elbow, and the needle is gently pushed or thrust through the skin into the vein. Meanwhile the saline solution is continuously running from it. The needle is held at about an angle of 10 to 15 degrees to the skin surface, depending on the prominence and caliber of the vein. Care must be exercised not to push the needle through both walls of the vein. This can be avoided by not introducing too long a surface of the needle into the tissues.

The patient previously has his arm carefully cleansed, a ligature in the form of an ordinary soft rubber catheter or tubing is tied around the middle of the arm, above the selected site of puncture, and the patient is requested to tighten the fist, to make the superficial veins more prominent.

As soon as the needle has entered the vein, the rubber ligature is released by an assistant, the stop-cock of the needle is reversed, and the salvarsan solution flows through the needle into the vein. Hence, there is no danger of any salvarsan solution getting into the subcutaneous tissues. No injection should be given intravenously in less than about ten minutes, and the solution must be quite warm when poured into the container so as to allow for its cooling when poured into the apparatus; when it enters the vein, the solution should be about the temperature of the blood. An ideal intravenous injection is painless.



Improved gravity apparatus for intravenous injection of salvarsan.

The needle will not produce cramping of the hand of the operator, as the thumb and middle fingers pass through the rings, and the index-finger rests on the corrugated plate on its superior surface, thus affording firm support and preventing the needle from changing position after it has entered the vein, which may occur if the patient coughs or sneezes. It affords a firm and comfortable hold, even if the operator wears rubber gloves, as I have invariably done in all my work in this line.

Another advantage of this needle is that the stop-cock is readily adjusted. While the needle is being introduced into the vein, blood must not be allowed to flow out of the vein and enter the tube containing the salvarsan solution. *Blood entering the needle at any time except* when the saline solution is constantly flowing out of the needle would have a *tendency to clot in it quickly* and block its lumen.

715 North Eighth Street.

THE SANITARY INSPECTION OF OYSTER-GROUNDS IN THE UNITED STATES[*]

C. A. FULLER, Ph.D.
Assistant Professor of Bacteriology, University of Wisconsin
MADISON, WIS.

The oyster industry forms a very important part of the marine fisheries of the United States. The market value of the products of the fisheries of this country (exclusive of Alaska) for the year 1908 was estimated by the Bureau of the Census[1] at $54,030,630. The income derived from the oyster trade alone, for the same year, amounted to $15,713,000, or nearly one-third the value of the total fishery products of the country.

The American oyster, *Ostrea virginia*, is found along the entire Atlantic coast from Maine to Texas. Two local varieties of oysters are also found on the Pacific coast. But the center of the oyster trade in America is confined to the Atlantic and Gulf states. The value of the product from these latter states amounted to $15,019,360 for 1908, while the output from the Pacific states for the same period marketed $695,640. Twenty-one states are interested in oyster production to a greater or less extent, the larger producers being Maryland, Virginia, Connecticut, Louisiana, New York and New Jersey. In 1908, Maryland marketed 6,231,967 bushels of oysters; Virginia, 5,075,014 bushels; Connecticut, 3,948,070 bushels; Louisiana, 3,650,456 bushels; and New Jersey and New York about two and a half million bushels each. South Carolina, Georgia, Rhode Island, Mississippi and Florida produced over 1,000,000 bushels each. The ten other oyster-growing states, with the exception of Maine and Oregon, marketed over 100,000 bushels each. In 1908 the oyster crop of the United States amounted to 33,329,925 bushels in market and seed oysters.

No very recent statistics on the extent of the oyster industry in other countries than the United States have been obtained, and in this connection reference is made to the data published by G. W. Fuller,[2] in 1905. This writer estimates the annual production of the United States at 28,138,434 bushels; of Great Britain at 2,760,000 bushels; of France at 2,000,000 bushels; of Holland at 70,000 bushels; and of the other oyster-producing countries at 610,580 bushels. From the above figures it would appear that the United States is by far the largest producer, and supplies the market annually with more than five times as many of these shell-fish as all the other oyster-producing countries combined. But, as is pointed out by Fuller, "these figures are not strictly comparable, as they refer in various instances to different years, beginning about 1890, and extending down to the present time (1905). But they serve to convey a general impression as to the relative extent of this important industry."

[2] Fuller, G. W.: Jour. Franklin Inst., August, 1905.

A considerable proportion of the oyster-grounds in the United States, especially in the southern part of the country, is found in open water, quite remote from any possible source of sewage pollution. The sanitary condition of these grounds is, of course, above suspicion. A large number of oyster-beds, however, are located in inland tidal waters, many of them in the vicinity of large cities and towns which discharge their sewage directly into tidal water or into streams flowing into tidal water. Thus, oyster-beds exposed to gross sewage pollution are found in Boston Harbor, in the Providence River, in New York and Long Island waters, in Chesapeake Bay and numerous other places famous for the quality of their oysters. The federal government has no jurisdiction over these areas and under the existing laws, cannot control the pollution of tidal waters or prevent the taking of oysters from polluted localities. Very recently, however, the government has taken a step in the right direction by prohibiting the sale of polluted shell-fish in interstate commerce.[3] This law went into effect May 1, 1910, and is in substance as follows:

> It is unlawful to ship or sell in interstate commerce oysters or other shell-fish which have been taken from insanitary or polluted beds, or which have become polluted by packing under insanitary conditions or by the use of unclean receptacles.

A second federal act,[4] in effect June 4, 1910, prohibits the shipment or sale of oysters "floated" in polluted waters. By the enforcement of these two measures the government hopes to control the shipment and sale in interstate commerce of polluted shell-fish, but places no restrictions on the sale of such shell-fish within the states in which they are grown.

The ultimate control of the oyster products in the United States, however, rests with the different state boards of health and shell-fish commissions, which should be vested with proper authority by their respective legislatures to act in cases of shell-fish pollution. Very carefully formulated and well-enforced laws protecting the natural oyster grounds and cultivated beds and regulating the sale or lease of land for oyster culture have been in effect in many of the principal oyster-growing states for some time. But it is only within the last few years that any measures have been taken to regulate the catch of oysters from polluted areas, or to prevent the sale of infected shell-fish in the local markets. Nearly all the more important oyster-growing states have caused their shell-fish grounds to be inspected by various authorities, but in most instances these inspections have been in the nature of hydrographic rather than sanitary surveys.

In 1901 the legislature of Massachusetts passed acts directing the State Board of Health to make annual examinations of the conditions about the main sewer outlets of cities and towns and to prohibit the sale of oysters and other shell-fish taken from polluted areas. The board was also empowered to examine all complaints relative to the contamination of tidal waters, and if necessary to fix the boundaries of such pollution, and prohibit the taking of shell-fish from areas thus defined. The Board of Health has made several extensive surveys of the productive localities, covering practically all of the shell-fish grounds of the state. These surveys include careful inspections of the shell-fish areas and the bacteriologic examination of several thousand oysters and many samples of sea-water. As a result of these investigations[5] approximately 1,500 acres of shell-fish grounds in Boston Harbor and 700 acres in New Bedford Harbor have been condemned, and the taking of oysters and other shell-fish from these localities prohibited by the fish and game commission acting under the direction of the board of health. A number of convictions have followed the violation of the above restrictions, and fines prescribed by law imposed. The situation in Massachusetts has been somewhat complicated by the passage of a bill in 1907, "permitting the taking of polluted shell-fish for bait on securing permits from the board of health, and providing heavy penalties for both buying and selling. As a matter of fact, it is well-nigh impossible to enforce this law . . . and complete prevention from the taking of such shell-fish is the only method by which the public health can be properly safeguarded."

A careful and thorough investigation of the whole problem of shell-fish pollution has been carried out by the Massachusetts Health Department during the last ten years, with the result that much of the very best work in this country along these lines has been done in the bacteriologic laboratories of the Lawrence Experiment Station. Up to the present year Massachusetts has been the only state to recognize the importance of this question sufficiently to legislate against the taking of oysters and other shell-fish from badly polluted areas, and to enforce its legislation.

In 1908 the State Board of Health of New York made an extensive survey of the more important oyster-grounds of the state. The outlets of sewers and all other possible sources of pollution as far as the oyster-beds were concerned were located; the effect of tides, currents and winds were studied in so far as the time at the disposal of the department permitted; and bacteriologic analyses of oysters and water samples from various localities along the New York and Long Island coast were made. The time at the disposal of the board for these investigations was somewhat limited, and[6] "while the results of the field and laboratory work are in close harmony, the studies can only be considered as preliminary, and as such the department is not warranted in passing final judgment on the results, for the purpose of administrative action." Yet a large percentage of the oysters examined bacteriologically would be considered polluted, if judged by the usual standards, on the strength of the figures published in the report of the board. The department of health has, however, been endeavoring to control the evident pollution of tidal waters under its jurisdiction and its "policy since 1905 has been that further and unrestricted pollution of the waters of the state should cease, and in so far as the department has the power, the existing discharge of raw and ineffectively treated sewage should as rapidly as possible be prohibited."

The sanitary aspect of the oyster industry in Virginia was investigated in 1909 by the state board of health in conjunction with the state board of fisheries. This investigation included a careful sanitary survey of all the oyster-growing districts of the state with the bacteriologic examination of representative samples of oysters and sea-water from all localities; also an examination of the method of handling oysters for shipment, shucking and packing, and of the alleged practice of "floating" of "drinking" oysters for the purpose of increasing the bulk of the product. The results of these investigations[7] show that the majority of the oyster-grounds of Virginia are "perfectly safe from a sanitary point of view. The streams condemned are small and constitute only a small percentage of the oyster-grounds of the state. Steps have already been taken to prevent the sale of oysters from these areas, and their sale will not be permitted in the future under any circumstances." In addition to the general survey of the oyster-grounds of the state, frequent inspections of the suspected localities are made by the department of health and the dairy and food commission, and planting in areas found to be polluted is prohibited by the local authorities acting on the advice of the inspecting boards.[8] Certificates of inspection are also issued by the department of health to approved grounds, stating that the grounds in question have been inspected by the department and found free from dangerous pollution; and that oysters taken from these grounds are safe for human consumption. The department of health has been very active during the past few years in controlling the hygienic condition of the oyster-grounds of the state, and has the problem well in hand. At the present time the sale of oysters taken from any territory known to be polluted is prohibited by law.

[4] U. S. Dept. of Agri., Food Insp. Doc. No. 121, May, 1910.

[5] Report Fish and Game Commission on Mollusk Fisheries of Mass., 1909.

[6] Twenty-Ninth Ann. Rep. N. Y. Dept. Health, 1908, p. 833.

An act of the New Jersey legislature, in effect April 6, 1910, directs the board of health[9] "annually or oftener if the board considers it necessary, to inspect the oyster and clam beds within the state for the purpose of ascertaining the sanitary condition of the same." Official records of each inspection are kept and certificates setting forth the results of inspection are issued to the parties concerned. The taking of shell-fish from areas condemned by the board of health, with the intent to sell for food, is an offense punishable by a fine of $100.

The Dairy and Food Commission of Texas[10] makes annual inspection of the oyster-beds along the Texas coast, but there are no specific regulations applying to cases of shell-fish pollution.[11] The Texas pure food and drug law, passed by the legislature March 20, 1909, which is in the main a copy of the federal act, might possibly be construed to regulate the sanitary condition of the oyster industry of the state, but contains no specific reference to polluted oysters.

A sanitary survey of the oyster-grounds of Rhode Island was made by Fuller[12] in 1901-02. These investigations showed that the beds in the Providence River and upper portion of Narragansett Bay were badly polluted with sewage. There are, however, no state laws prohibiting the planting or dredging of oysters from polluted sources or their sale for food.

The surveys of the oyster-grounds which have been made in other states were mainly in charge of hydrographic engineers or biologists studying the problem of oyster-culture, so that little or nothing in the nature of systematic sanitary inspections has been accomplished. Various state laboratories have been called on from time to time to examine bacteriologically samples of oysters and other shell-fish for suspected sewage pollution, but up to the present year no systematic sanitary surveys of oyster-grounds, including the bacteriologic examination of oysters and other samples have been made except in the waters of Massachusetts, New York, Virginia and Rhode Island.

One of the most perplexing problems which has been brought up by the investigation of the pollution of shell-fish by sewage is the determination of accurate or safe standards of pollution. At the present time several state boards of health are independently making special efforts to formulate a series of tests by the application of which the analyst can determine with a fair degree of accuracy the amount of pollution of shell-fish and water and report correctly whether or not oysters taken from any given locality are safe for human consumption. In the main, these tests consist in bacteriologic analyses of samples of oysters and water from suspected grounds, with the purpose of determining the presence or absence of the colon bacillus, the characteristic organism of sewage.

Early investigations have shown that this organism is not normally found in unpolluted sea water or in shell-fish taken from unpolluted sources. In their report on the investigation of the pollution of shell-fish by sewage, the Massachusetts Board of Health[13] states that "the evidence gathered in this work is fairly conclusive that *B. coli communis* and the streptococcus are not normal inhabitants of the shell water or body of either oysters or clams, and that their presence there must be considered proof of pollution." At a later date, Gage[14] states that "*B. coli* and sewage streptococci are absent or present in only a small proportion of samples [of shell-fish] collected from sources remote from pollution. On the other hand, the test organisms are always present in a majority of samples from sources whose pollution is evident."

Fuller[12] in his study of the oyster-beds of Rhode Island, found that *B. coli* was not normally present in oysters or sea-water collected from localities remote from sewage pollution.

The results of the bacteriologic analyses of market oysters obtained by the Connecticut Board of Health are similar to the above.

After the examination of a considerable number of oysters from presumably unpolluted sources, the Virginia Health Department[7] concludes "that the colon bacillus is not found as a normal inhabitant of the oyster either of the natural fluid of the shell or of the intestine."

The investigations of Hewlett,[15] Klein[16] and Houston,[17] point toward the same general conclusions. Dr. Houston says, "As regards deep-sea oysters, results are not quite decisive, but point strongly to the conclusion that not only typical *B. coli* but as well coli-like microbes are absent from them."

Evidently the weight of opinion leans toward the view that the colon bacillus is not found in shell-fish under normal conditions, and that mollusks containing this organism must be contaminated. But it is obvious that longshore oyster-grounds, particularly those in the neighborhood of cities and towns, are rarely if ever free from sewage pollution to some extent, so that in the majority of cases in which the sanitary condition of oyster-beds is under investigation, the question of standards of pollution becomes rather a problem of determining the amount of pollution permissible without danger to health, than one of determining merely the presence or absence of characteristic sewage bacteria in oysters and the water in which they grow.

[17] Fourth Rep. Royal. Comm. on Sewage Disposal, 1904, iii.

Fuller[12] has regarded as polluted all shell-fish which were found to contain *B. coli*, but in the work in Rhode Island in 1901, he did not attempt to fix an arbitrary standard for the condemnation of oyster-grounds, beyond the determination of the presence or absence of sewage pollution as indicated by the bacteriologic analysis of these shell-fish for *B. coli*.

Conn[18] has regarded "all oysters contaminated which have shown the presence of *B. coli*." This "work has been on market oysters and not on oyster-beds" so that "no rule as to the proportion of contaminated oysters necessary to condemn an oyster-bed has been formulated" by him.

The New York Board of Health[19] did "not attempt to fix standards of pollution" deduced from their own experiments, merely "tabulating their results on the basis of the relative conditions as found" and using the "*assumed standards*" of other bacteriologists.

The federal government[3] has recognized the possibility of fixing a standard of shell-fish pollution by the food inspection decision of Oct. 14, 1909, in which it is stated that "the pollution of oysters with sewage can be readily detected by bacteriologic examination."

The Massachusetts State Board of Health has made a more thorough and systematic investigation of the whole problem of shell-fish pollution than the other health departments in this country, and for this reason the opinion of the Massachusetts authorities on this question is frequently sought by outside laboratories. And up to the present time standards for judging the sanitary condition of shell-fish which have been worked out by the Massachusetts board have been used in many of the bacteriologic laboratories in the United States. The position of the Massachusetts Department of Health on this question has been stated by Gage[14] as follows:

> With a sufficient number of samples the absence of *B. coli* or of positive fermentations followed by an overgrowth of streptococcus can be safely taken to indicate freedom from pollution, and when ten individuals are tested, a negative test in eight out of ten or 80 per cent. of the samples, can be assumed to be an indication of reasonable safety. Under the same conditions, a positive test in 50 per cent. or more of the samples must indicate pollution of a more or less dangerous character. Between these extremes, the interpretation is a question of individual judgment for which no hard and fast rules can be made.

In these tests the water within the shells and the intestinal content of suspected specimens are tested by the usual methods of water analysis.

The above statements unquestionably represent the fairest grounds that can be taken on this important question with the present knowledge of the subject. The examination of single specimens of shell-fish can have no more value than the bacteriologic analysis of isolated samples of water from unfamiliar sources. Sanitary inspection of the grounds themselves is often of greatest service in interpreting the results of laboratory analyses, and sometimes absolutely necessary in order to form a correct judgment when the bacteriologic examinations are of a doubtful character.

The period is distinctly constructive in tendency. Much work on the problem of shell-fish pollution is now in progress in American laboratories. Massachusetts and Virginia have been most active and apparently have the problem well in hand. New York has made a preliminary survey of its oyster-grounds, but the department of health does not feel that it has done sufficient work to warrant the fixing of definite standards of shell-fish pollution. New Jersey[20] is now taking active measures to control the hygienic condition of its large shell-fish areas. The shell-fish commission of Rhode Island is now making a very comprehensive survey of the waters of the state. Connecticut[18] is about to commence a sanitary survey which will cover all the tidal waters of the state. The Maryland Health Department[21] is examining bacteriologically various samples of market oysters but have formulated no standards of pollution. The present year will unquestionably be productive of important results which will add to the knowledge of the problem of shell-fish pollution and aid in formulating a more accurate and safer standard of pollution.

Note: Since the preparation of the above paper, the results of several laboratories, which have been engaged on oyster work during the past year, have been presented at the meeting of the American Public Health Association. The situation was carefully gone over and proposed standards of purity discussed. Among the more prominent of these was that recommended by the United States Bureau of Chemistry which has in charge the bacteriologic examination of oysters and other shell-fish for pollution under the food and drug acts of 1909-1910. This standard condemns all oysters in the shell which "show the presence of *B. coli* types of organisms when present in three out of five oysters in 0.1 c.c. of the shell liquor. These examinations are supplemented by an inspection of the beds from which the oysters were obtained, also by the bacteriologic examination of the water bathing the oysters from these localities.[22] The government has prevented the shipment and sale of several lots of these shell-fish which have not come up to the standard.

The survey of the oyster-grounds of Rhode Island has also been completed. The state shell-fish commission has used the federal standard of purity in interpreting the results of bacteriologic analysis and has condemned and refused certificates of inspection to more than half the oyster-grounds of the state, comprising an area of over 3,000 acres of cultivated oyster-grounds. About 25 per cent. of the beds were passed conditionally, subject to later inspection. Official certificates of inspection were issued by the commission only to grounds which came up to the federal standard of purity.

While a number of bacteriologists have employed the standard of the federal government in judging the sanitary condition of oysters, the general opinion of the American Public Health Association seems to be that it is too high. The committee on standard methods of analysis failed to recommend a definite standard of purity for shell-fish analysis since they felt that further investigation of the problem must be carried on before they were warranted in adapting any definite standard. The federal standard is a tentative one and "as yet there are no established standards for the bacteriologic examination of shell-fish."[22]

Acid Intoxication in Cholera.—During the stage of reaction in cholera it is not uncommon to see an almost abnormally bright color of the mucous membranes associated with a type of dyspnea approaching air-hunger. Such patients usually have either a partial or complete suppression of urine and an increase in the blood-pressure, which is sometimes as high as 200 millimeters of mercury. In cholera the symptoms of acid intoxication become so intimately related to those of uremia that differentiation is hardly possible. Indeed, it has been suggested by Senator that uremia from any cause whatsoever is only an acid intoxication.—A. Watson Sellards, in *Philippine Journal of Science*.

THE PLAGUE IN NORTH CHINA

J. J. MULLOWNEY, M.D.
PEKIN, CHINA

The plague is very properly divided into three types: the bubonic, or that from affecting the lymphatic system which is usually the most common type; the septicemic, or that affecting the blood-system; and the pneumonic type, or that affecting the lungs more especially. The latter two types are usually most fatal.

The epidemic which was, in January, 1911, overrunning North China was of this last type—the pneumonic type—largely and of excessive virulence; although there were, as in all epidemics of this disease, some cases of the other two types, and more of the septicemic type than of the bubonic type. So far as our experience here is concerned—and that experience is confirmed by reports coming from other infected regions—scarcely any who have taken the disease have recovered.

The disease, so reports have it, has been found in sporadic cases, and even in small epidemics in southern Russia for several months, but the Russian authorities took strenuous methods to eradicate it and they had got it fairly well under control in Russia when in November, 1910, it was found to have come to Harbin. Harbin is in Manchuria, which, as is well known, is under the control of the Chinese government. Harbin is moreover on the Trans-Siberian railroad.

It is interesting to know how the disease got to Harbin. It is now believed that the disease was brought to Harbin through the infected hides which hunters and trappers brought to Harbin for market. It is known now that there was an epidemic among a certain fur-bearing animal, an animal something like the American muskrat, which the hunters of the north kill for the hides and sell in large quantities at Harbin. It has been found that the disease among these animals was due to plague; and the furs brought to Harbin for sale are believed to have brought the infection. Whether this be absolutely true, or whether the disease was brought to Mukden, Shanhaikwan, Tientsin, and Pekin through persons traveling on the railroad cannot be stated definitely. The fact is that Harbin was the original hotbed of the disease. It spread from there in all directions, usually following the lines of traffic, the principal of which is, of course, the railroad. The city of Harbin is divided into a Russian, a Japanese, and a Chinese part. The Russians and the Japanese took strenuous measures at once to stamp out the disease in their quarters, and they have it well under control, in their respective parts of the town; but the Chinese problem was a much more complex one, and their people much more numerous and perhaps less enlightened; consequently, the disease got beyond their control and it was from the Chinese native city of Harbin that the disease spread. The thing to do would have been to stop all railroad traffic from that city early in the epidemic, but that meant, of course, great loss of money and much inconvenience; so it was allowed to go on until, I fear, it was too late, for this disease in January was found as far south as Chefu, and had got to several towns some distance away from the line of the railroads. This meant that it would spread inland, for the Chinese villages and towns are numerous and usually not far apart in this region, so that people traveling by cart and on horseback would spread it to other inland villages.

If the disease gets to Central China, where the climate is warm and damp, it will find a soil excellently adapted for the spread of the disease. It may die out here in the North with the coming of the warm dry season, but with the coming of the wet season again it will be, doubtless, brought up from the south and central provinces again and practically become endemic unless the Chinese authorities employ most stringent methods to check the spread of the disease at once. It is due to them to say that they were in January rushing both foreign and Chinese doctors and assistants to the cities of Harbin, Mukden, Shanhaikwan and Tientsin, which are the largest cities on the line of the Imperial Chinese and the Manchurian railroads, but I fear that they waited too long. January is a most advantageous time of the year for the spread of the disease, for thousands of coolies at that time are returning from Manchuria to the provinces of Chili, Shantung, etc., after having spent a summer and fall in earning their bread in the wheat fields or lumber forests of Manchuria, and also because it is just about the time of the Chinese New Year, when every Chinaman who can returns to his home for the festive season.

But to get down to a few more specific data about this epidemic: 1. The disease started at Harbin. Up to January 24, 1911, about 1,500 Chinese and twenty-seven Europeans had died, of whom two were physicians and one an assistant. 2. The disease is met with, mostly, in the pneumonic and septicemic types. 3. Inoculation with Haffkine's antibubonic vaccines seems to be of considerable value as a prophylactic measure. 4. The administration of Yersin's serum in treatment does not seem to be of much value, although it should be said that it has not been given a full trial. If it were possible to take, say, forty or fifty cases and administer the serum to the patients and compare them with a like number that had not had the serum, we could say something more definite, but so far as I am able to learn this has not been done in this epidemic. 5. It has been conclusively shown that the disease, in the pneumonic form, is transmitted by the sputum and by contact with persons sick of the disease, and that the wearing of respirators is good prophylaxis. 6. The rat, or the rat flea, does not seem to have nearly as much to do with the spread of the pneumonic type of the disease as it has in epidemics of the bubonic type. 7. So far as I am aware this is the first definite epidemic of the pneumonic type of the bubonic plague. 8. The disease spread along the line of railway traffic from Harbin to Mukden, to Shanhaikwan, to Tientsin and to Pekin and to several smaller places. It also got to Chefu, which is a seacoast town, probably through some Chinese coolies returning from the North in a Chinese junk or fishing boat.

Hopkins Hospital, Methodist Mission.

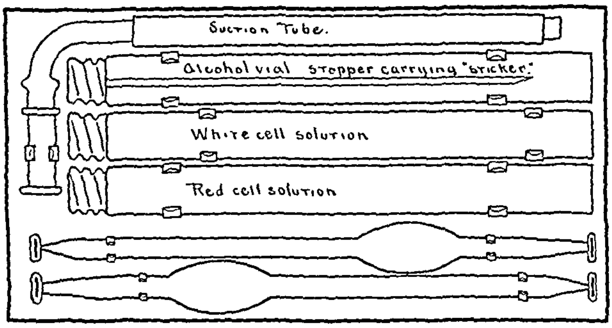
A HANDY POCKET CASE FOR BLOOD PIPETTES AND SOLUTIONS

WALTER S. SUTTON, M.D.
KANSAS CITY, MO.

The inconvenience of carrying about the usual blood-pipette case and separate solution bottles has resulted in many efforts on the part of pathologists, hospital interns and others to devise a convenient means of collecting and carrying pipettes and smears of blood. The device herewith figured meets all the requirements in perhaps the smallest possible space, since the entire outfit may be comfortably carried in the vest pocket. As is easily seen from the illustration, the set contains two pipettes, a 2-dram bottle of alcohol in the stopper of which is mounted a long cutting-edge needle, two

2-dram bottles containing diluting fluid for red and white cells respectively, and the usual rubber suction-tube. These are held in place on a thin metal plate by appropriate clips. The pipettes have in addition end-clips, each shod with a piece of soft rubber tubing, which, by pressing against the ends, prevent leakage from the filled pipettes. These, however, may be omitted in favor of short rubber caps for the pipette-ends, or of the time-honored rubber band stretched over the pipette from end to end. The straight portion of the suction-tube lies in a short piece of brass or copper tubing soldered to the metal plate.

I use two 1 to 100 pipettes, making either red or white counts with either pipette. Thus, the case will provide for two red-cell counts, two white-cell counts or one of each. Slides or cover-glasses for blood-smears are carried in the case simply wrapped in tissue-paper. The metal plate which carries the outfit is preferably fastened to the cover of the case, since the fastening prevents breakage and the low edges of the cover do not interfere with the removal of the pipettes or bottles from their places. The advantage of the clean needle continuously immersed in alcohol over the usual unclean pocket "sticker" need scarcely be mentioned. The actual size of the case is 4¾ by 2½ inches and the depth ⅝ inches.



Handy pocket case for blood pipettes and solutions.

Dr. F. Hecker has made the useful suggestion that if the depth of the case were slightly increased a Sahli hemoglobinometer might be added to the outfit.

PNEUMOCOCCEMIA; BILATERAL EMPYEMA; RECOVERY [*]

EDWARD A. ARONSON, M.D.
AND
HARRY OLSAN, M.D.
Adjunct Attending Physician at Mount Sinai Hospital;
Intern at Mount Sinai Hospital
NEW YORK

Patient.—M. D., a boy aged 4½ years, was admitted to Mount Sinai Hospital June 14, 1910. He was the second of four children. The mother had had no abortions; father denied syphilis; the other children were all healthy. The delivery of this child was normal; it was breast-fed, and always well up to time of its present illness.

Present Illness.—This began with an eruption four weeks before admission. This eruption was described by the father as a "red shine." At the onset there was fever but no vomiting. The duration of the fever was not noted, but the child appeared well enough two weeks later to be taken out and exposed to cold, which was followed by elevation of temperature, slight cough, generalized edema of the face and body and bloody urine. A physician, called in for the first time on the latter occasion, diagnosed the condition as postscarlatinal. The child did not improve and was admitted to the hospital two weeks later, June 14.

Examination.—On admission physical examination showed that the general condition of the child was very poor; there was marked apathy, and extreme dyspnea and cyanosis. In short, the child looked almost moribund. The throat showed slight reddening. The chest showed marked inspiratory retraction of the lower ribs.

Lungs: The lungs anteriorly were negative; posteriorly the right lung showed flatness over the entire chest almost to the apex; breathing was diminished above, absent below. On the left side there was dulness from the angle of the scapula to the base, where it became flatness; no breathing at the base.

Heart: The apex beat could not be made out; right border, mid-sternum; left border, one finger-breadth outside of nipple line; action was regular, rapid, and of small force, and the pulse was of correspondingly poor quality.

Abdomen: Slightly distended and tympanitic; no tenderness anywhere.

Liver: Fifth space above and felt three finger-breadths below the free border of the ribs; edge sharp and not tender.

Spleen: Palpable one finger-breadth below free border of ribs.

Skin: A few small pustules over the chest, and the abdomen was covered by a number of dry crusts. Desquamation was noted on palms of hands and soles of feet.

There was some glandular enlargement.

Urine: Normal, grossly and microscopically.

Blood-Count: Leukocytes 23,800; polynuclears 82 per cent.; large lymphocytes 5 per cent.; small lymphocytes 11 per cent.; large mononuclears 2 per cent.

At the time of admission the pulse was 128; respiration 58; and temperature 101.4 F.

A bilateral *empyema was suspected and then confirmed* by aspiration.

Treatment and Course of Disease.—On account of the patient's poor condition, it was decided to relieve him at once, at least temporarily, by aspirating the left chest; ten ounces of pus were withdrawn. This afforded him some relief but *four hours later, under local anesthesia, an intercostal incision* was *made by Dr. Leo B. Meyer*, the surgeon in charge of the service, and pus was evacuated; a drainage-tube was inserted, and the patient reacted well after the operation. The child's condition precluded any more radical procedure than simple incision.

June 17, two days later, the patient's condition became very poor again; the dyspnea increased and the temperature ran up to 104.2 F.; respiration 60 and pulse 160. The left side was discharging freely, but owing to his poor condition, we decided to resect a rib on the right side two fingers below the angle of the scapula. This was done without anesthesia, by Dr. Meyer. Drainage was introduced and the wound dressed.

June 18: Patient's condition improved; respirations less labored, and pulse still rapid. The patient did fairly well for the following ten days when the temperature began to rise again, although both sides were discharging freely.

June 1: General condition *poor; patient* complained of some pain in the right hypochondrium and some tenderness in this area. Wounds look clean and are discharging quite freely.

July 4: Temperature 103.6 F.; pulse 140; tenderness over the whole liver area, some bulging in the lateral aspect of the upper right abdomen.

July 6: On the fifth the temperature dropped from 103.8 to 97.4 F.; general condition very poor; heart irregular at times; quality of pulse fairly good; liver area remained about the same. There was a swelling in the right cheek directly over the superior maxilla, showing slight fluctuation.

July 8: The face swelling increased in size, and was incised through the mouth. A large amount of very foul pus was evacuated. This pus contained a large number of saprophytic bacteria. A blood-culture made showed the presence of pneumococci.

---

[*] From the Isolation Service, Mount Sinai Hospital.

July 11: Owing to the frequent variation in temperature and the persistent tenderness in the right hypochondrium, the right subphrenic space was repeatedly aspirated, but no pus was found.

July 13: General condition somewhat worse; marked cyanosis and dyspnea noted; wound of the right cheek drained well. The lung signs showed dull tympany over the front of both lungs, some dulness and even flatness behind with numerous fine crepitant râles over the whole lung area. The heart was negative. The child was unable to sit up without apparent pain and difficulty in breathing. Lying on the right side caused the child to cry out and become markedly dyspneic and cyanotic. The liver was enlarged and tender, though somewhat less so than formerly. The bulging over the liver area was unchanged; spleen still palpable.

July 19: Until this time the child was in fair condition, but on this day the temperature rose again to 104 F.; this rise was due to retention of pus on the right side. The pus was evacuated and the wound drained.

July 27: A second blood-culture showed the absence of pneumococci.

July 29: Temperature rose on this date, due to retention of discharge.

August 1: Condition better; liver tenderness less marked; heart action rapid, regular, and fair. Dr. A. V. Moschcowitz was asked to see the patient on account of suspected subphrenic abscess. His opinion was that there was retention above the diaphragm, and he advised more complete drainage. This was done and the signs rapidly cleared up.

August 10: The condition of the wound on the right side was very much improved; probe could still be introduced for several inches; discharge was slight and of a serous character.

August 13: Discharge had entirely ceased; wounds closed; liver tenderness had disappeared and the child was discharged cured.

A study of the case shows the following facts: 1. The child had scarlet fever. 2. Two weeks after the onset of the first symptoms he was probably exposed to a pneumococcus infection. 3. On admission there was no evidence of pneumonia, but of a bilateral empyema. 4. A pneumococcemia was shown by a blood-culture taken on July 8. 5. There was a possible metastasis in the cheek. Recovery ensued.

We find that the presence of scarlet fever was shown by the history of a rash, and of a general edema, and by the desquamation of the hands and the soles of the feet on admission. Many authors make but casual mention of the occurrence of empyema after scarlet fever, although we do know that it may occur after any of the infectious diseases. While empyema is of frequent occurrence, bilateral empyema is rather rare and varies according to different authors. We can say, however, that it occurs in from 1 per cent. to 3 per cent. of all cases of empyema. The pus in empyema following scarlet fever most frequently contains the streptococcus or the staphylococcus, and less often the pneumococcus, which, if present, may follow as a result of a pneumonia complicating the scarlet fever. As to the pneumococcus infection, we have a history of probable exposure to the pneumococcus two weeks after the onset of the first symptoms. The patient may, at that time, have had a pneumococcus infection of the lung, of which on admission, two weeks later, there were absolutely no signs.

Endeavoring to account for the pneumococcus infection, we find that our patient was exposed two weeks after the onset of the scarlatinal symptoms. We know that the pneumococcus inhabits the normal throat. Taking into consideration the diminished resistance of the child following scarlet fever, plus these pneumococci, (which, as Arnold and Grawitz have shown, can pass through the lung tissue and into the pleural cavity without infecting the lungs), plus a hydrothorax accompanying the general edema, we can perhaps conclude that the pneumococcus empyema possibly followed such an infection.

Desguin, in his excellent monograph,[1] says that a pneumococcus infection of whatever part of the body is always accompanied by a pneumococcemia. He states further that the pneumococcemia may precede the appearance of a local lesion. As the presence of the pneumococcus in the blood is not a normal condition, in our case the micro-organism may have entered the blood from the congested throat usually seen in scarlet fever. From this it may also be possible that the empyema was secondary to the pneumococcemia. We must not lose sight, however, of the fact that there may have been a preceding pneumococcus pneumonia followed by empyema, although from the history and the signs on admission this could not be positively determined. The empyema was confirmed by the aspiration of pus from both sides of the chest, each of which showed the presence of pneumococci as reported by the pathologic department: Pus from left chest: pneumococcus, polynuclears 100 per cent.; pus from right chest: pneumococcus, polynuclears 97 per cent., lymphocytes 3 per cent.

The first blood-culture also showed the pneumococcus as seen from the following report: Culture made by Dr. Olsan July 8, 1910, 5 c.c. of blood being used. This blood was incubated partly in glucose-bouillon, partly in agar, and partly in 2 per cent. glucose-agar. In all the media pneumococci were found, there being on solid media seven colonies to the cubic centimeter of blood. The organism was typical in every respect. This culture was found positive six weeks after probable infection, which is an unusually long time for a pneumococcemia to persist, according to Desguin. A second blood-culture was made by Dr. Celler July 22, 1910, 5 c.c. of blood being used. This was incubated in glucose-bouillon, in agar, and in glucose-agar. All the media remained sterile, the time of observation being six days.

At the time the face induration appeared pneumococci were still probably present in the blood, and although pneumococci were not recovered from the pus evacuated from the swelling, owing to exuberant growth of saprophytic bacteria, there is a strong likelihood that this focus can be considered a metastasis. Two weeks after the first culture was made, a second was taken and found to be negative. At the time the general condition of the boy improved considerably, and although at times there was a tendency for the temperature to rise again it was always found to be due to slight retention of pus. Dr. Meyer in his comment on the case says, that from the surgical standpoint the method of treating a bilateral empyema is of interest, especially if the patient is in as bad a condition as this one was. To have opened the two sides of the chest at the same time would probably have been fatal. Incision and drainage of one side so as to give the child some lung with which to breathe, and to permit some lung expansion on one side before opening the other, seems to be the best method of procedure. If the child's condition had not been so desperate, rib resection would have been performed at the first operation, but the first consideration was to get the chest opened and drained and the child removed alive from the operating-table.

As a matter of fact, in young infants, intercostal incision is frequently sufficient and is certainly worthy of a trial as being the simpler operation. In this case drainage was as satisfactory from simple incision as from the site where the resection was done. Up to this time, three months after discharge from the hospital, the boy has remained entirely well.

FRACTURE OF THE CLAVICLE

ITS DIAGNOSIS BY TRANSMISSION OF RESPIRATORY SOUNDS *

SEWARD ERDMAN, M.D.
Adjunct Assistant Surgeon to Bellevue Hospital; Assistant Attending Surgeon to Lincoln Hospital
NEW YORK

In a paper, read before The Society of Practical Medicine in May, 1907, entitled, "Diagnosis of Fracture of the Clavicle by Auscultation of Voice and Breath Sounds," I called attention to the fact that in normal individuals there is distinct transmission of both voice and breath sounds probably from the trachea, outward along the shaft of the clavicle to its outer extremity.

When a small-belled stethoscope is accurately applied to the outer extremity of the clavicle, breath sounds and voice sounds of a distinctly bronchial or tracheal quality are to be heard.

In a series of over 300 normal persons thus tested, it appeared that the whispered voice was the most reliable test and that in over 95 per cent. of all the cases a more or less intensely bronchial whisper could be heard over the acromial end of the clavicle.

In over two-thirds of the cases the spoken voice as well as the whisper was of this quality, and audible. In about one-third of the cases the respiratory murmur was distinctly audible and of this bronchial character, in addition to the spoken and whispered voice.

It was also noted that the transmission of these sounds was limited very strictly to the area over the shaft and outer extremity of the clavicle, and that if the stethoscope were moved even one-half inch forward, or outward, or backward, away from the clavicle, the sound transmissions were lost or so completely modified as to offer a clear demarcation.

Conclusions: Granted that there exists normally a transmission of voice sounds from the trachea outward along the clavicle, a fracture of the bone should cause a break in sound propagation; and such is found to be the case.

In the series of fifteen cases reported at that time, the results were most striking, for, in all these cases of fracture, there was complete loss of these auscultatory signs on the injured side, in contrast to their presence on the normal clavicle. In one case of green-stick fracture, the intensity of the sounds was very much diminished although they were not entirely lost.

As bony union takes place, there is a gradual return of these signs, but this does not seem to occur until after the fourth week from the time of fracture.

In cases of prominence of the inner fragment of the clavicle, it is often very easy to place the stethoscope over this fragment and to recognize clearly the sounds which no longer are audible over the outer fragment.

TRANSMISSION OF FREMITUS

Since writing the above-cited paper, I have made use of a still simpler method, based on the same principles, but dependent on the fact that vocal "fremitus" is likewise transmitted along the clavicle unless there be a break in the continuity of the bone.

Whereas the diagnosis with the stethoscope as above mentioned can usually be made, nevertheless there are a number of patients, especially children, who apparently cannot whisper and thus the test is rendered unsatisfactory; or there is difficulty in applying the stethoscope.

On the other hand, the recognition of vocal fremitus by the palpating finger is more easily attained and even the cries of the youngest child afford means for this test.

METHOD

The examiner stands directly behind the patient, who should best be seated on a plain stool or chair. Place the thumb or index-finger of each hand on the corresponding clavicle of the patient, and without pressure.

Commencing near the sternal end of the shaft of the clavicle gradually move the examining fingers symmetrically outward along the clavicles while the patient repeats some sonorous words, e. g.: "ninety-nine, ninety-nine, etc."

In the absence of a fracture the palpable fremitus will be easily detected and of equal intensity on the two sides, all the way out to the extreme end of the bone.

If there be a complete fracture, the fremitus is suddenly lost or very greatly lessened at the point of fracture and beyond. So delicately may this sign be elicited that it is often possible to follow accurately the obliquity of the line across the shaft at the point of fracture.

The normal fremitus of the whole scapular region and chest is very different in intensity and is easily distinguishable.

VALUE OF THE METHOD

In many cases of fracture of the clavicle, inspection alone, or the most superficial palpation, reveals without difficulty the presence and the site of the break, and no further examination is necessary; but for the above method I claim the ease with which the signs are to be elicited, the freedom from painful palpation of the fractured bone, and its great value as an aid in the diagnosis of the cases in which the fracture is in the outer end or in the shaft without deformity, and in all doubtful cases.

LITERATURE

Auscultation to elicit crepitus at the site of fracture has long been in use, especially for fracture of the ribs; but in 1893, Vajana[1] of Palermo described a method for diagnosis of fractures of many of the long bones and bones of the skull by combined percussion and auscultation.

The stethoscope is placed on a subcutaneous portion of the bone and, with the plexor and pleximeter, percussion is now made at points along the bone in all directions from the stethoscope, and when a line of fracture is crossed there is loss of the sound transmission.

In 1902, J. Plesch[2] of Budapest, described the same method as original, having doubtless overlooked Vajana's communication.

A. H. Andrews[3] suggests the use of the tuning-fork instead of the plexor and pleximeter.

---

* Comunication received July, 1910, for publication.

[1] Riforma med., June, 1893, ix, part 2, p. 651.
[2] Ungar. med. Presse, August, 1902, vii, 497.
[3] Chicago Med. Recorder, 1903, xxiv, 182, 185.

However, in the case of the clavicle, neither percussion nor tuning-fork is necessary, for the vocal and respiratory organs by way of the trachea, which is so close to the inner end of the clavicle, furnish all needed vibrations for our test, and, moreover, these are transmitted in a uniform direction, outward.

TUMOR IMPLANTATIONS IN THE DEVELOPING EMBRYO

EXPERIMENTS WITH A TRANSMISSIBLE SARCOMA OF THE FOWL*

PEYTON ROUS, M.D., AND JAMES B. MURPHY, M.D.
NEW YORK

The fate of tumor cells implanted in the developing embryo has from several points of view a considerable interest. The superficial similarity between neoplastic cells and the cells of embryonic tissue is striking; and it has given rise in part to a widely discussed theory of tumor origin. While this theory well explains a certain class of congenital growths, its more general applicability is questionable. But there is no doubt that the parallel study of embryonic and neoplastic cells can throw much light on important problems of growth.

MATERIAL USED

The implantation of tumor in developing embryos does not seem to have been accomplished heretofore, despite the evident bearing of such an experiment on the supposition that all tumors are of congenital origin. Indeed, it is most difficult with mammalian material, although we have found it not impossible. After laparotomy of the pregnant rat under ether, a fine, hollow needle is run for some distance in the uterine wall, and thence into the amniotic sac and embryo. When the needle is withdrawn after the injection, there is usually little loss of amniotic fluid. But the percentage of failures from one cause and another is high, and since it is necessary for the survival of the injected embryo that it be large, birth takes place before the tumor has opportunity to grow.

The difficulties are less with developing hen's eggs and a transmissible avian sarcoma.[1] But before describing our results mention should be made of a unique and significant finding recently obtained with this tumor, and now repeatedly observed. It is transmissible to new hosts by means of a filtrate free of the tumor cells.[2] The tumor has also been successfully transmitted in adult fowls by means of dried material kept at room temperature for three days. Nevertheless the growth metastasizes by the proliferation of transported cells and its tissue is in the strict sense transplantable.[3] Indeed, it exhibits to a special degree, not merely a few, but all those features by which the malignant neoplasms are characterized.

METHOD

For the inoculation of the sarcoma into developing chick-embryos, we have slightly modified a method devised by Peebles[4] for another purpose. A small window is cut in the egg-shell, a smaller one torn in the shell membrane, and through a needle a minute portion of the finely divided tumor is injected into the chick, now plainly visible. The window in the shell is then closed, preferably with the piece first cut out, and is sealed with strips of moist shell membrane.

When the operation is conducted carefully and with sterile instruments, many of the embryos continue to develop. The eggs used were laid by pure-bred fowls of the variety most susceptible as hosts for the tumor, namely, barred Plymouth Rocks. At the time of inoculation, the embryos were from six to sixteen days old. Most of our observations thus far have been on tumors in the embryonic membranes, because here even small growths are sharply defined and easily accessible. Furthermore, it is difficult to inoculate the embryo without at the same time inoculating the membranes pierced by the needle.

GROWTH IN THE EMBRYO

When an egg is opened on the sixteenth day of incubation, and a week after a successful tumor inoculation, one observes a slight puckering and opacity where the needle was thrust through the outermost embryonic membrane (fused chorion and allantois). From without no tumor is visible, but on cutting and turning over the membrane, there is usually found on its inner surface at the scarred spot, a sessile nodule like a flattened sphere, of which practically the whole bulk projects into the allantoid cavity. The mass is firm, yellowish or grayish white, nearly opaque, with extremely well-defined contour. Dilated blood-vessels converge to, and course over it. The tumor, after only seven days' growth, may measure 1.2 cm. in diameter, and it is extremely striking to see so large a mass dependent on a filmy membrane for support and vascularization. Scattered near by are perhaps a few small nodules, 0.1 to 0.2 cm. broad, and sometimes others lie in the deeper membranes. In the embryo tumor masses are found along the track of the needle. Our observations on them have been few as yet. In the best instance found thus far—that of a nineteen-day embryo inoculated a week previously—a large mass lay in the chest wall and projected inward toward the heart. Sessile on this organ was another mass, and two smaller ones were embedded in the liver substance. All were invading the surrounding tissue.

We have once found a "rice-body" free in the fluid between the membranes. It was made up entirely of living and dividing tumor-cells, was unprovided with blood-vessels, and was quite bare of endodermal or ectodermal covering.

GROWTH CAUSED BY A CELL-FREE FILTRATE

Some Ringer's solution in which ground tumor had been suspended and shaken, was passed through a Berkefeld filter impermeable, under the same conditions, to *Bacillus prodigiosus*, and of the resulting fluid, small portions were injected into developing eggs. In one, after the lapse of thirteen days, small, discrete tumor nodules were found on the membranes. A microscopic examination of these well demonstrated the specific action on connective tissue of the agent causing the growth. The fluid had been injected into an extra-embryonic body cavity at a time when it was lined by mesoderm, and the tumors occurred as localized growths in this mesodermal lining. Some of them, like the mesoderm about them, were still bare of any covering on one side. During our experiments the ectoderm and endoderm have been often injured and presumably brought into association with the agent causing the growth, but they have never undergone a neoplastic change.

HISTOLOGY OF THE GROWTHS

The tumors obtained on implantation resemble microscopically those in adult fowls except that the cells lie in a loose reticulum and are often of most attenuated spindle form. Slight variations occur in the morphology of the different growths, owing presumably to variations in the implanted material. But the cells are of one type, growing in a diffuse mass; and a cellular reaction is quite absent from the normal tissue round about. In general appearance the tumor cells are markedly different from those of the normal embryonic connective tissue next to them.

SUSCEPTIBILITY OF THE EMBRYO

Some embryos are naturally resistant, as are some adult fowls, and tumor implantation in them fails of success; but in most, the growth greatly surpasses that seen in adult hosts. This refers only to tumors in the embryo's membranes, since the implantations in the embryo's body have been as yet too few for a generalization. But there the findings will probably be the same. It is well known that young animals form more favorable hosts for transmissible tumors than do old. One of us has recently investigated the point further by inoculating with tumor many new-born rats and mice. These showed themselves much more susceptible than control animals three-fourths grown.

PRIMARY ORCHITIS WITH SECONDARY PAROTITIS

THE REVERSE OF METASTATIC MUMPS

J. F. TORPEY, M.D.
NEW HAMPTON, IA.

The case in question is that of a young man, aged 18, in high school.

Dec. 3, 1910, the patient was found in bed with temperature 101 F., pulse 90, complaining of pain and tenderness in the left testicle. I questioned him as to his having had mumps recently, the disease being prevalent at this time. He denied ever having had mumps, lues, gonorrhea, tuberculosis or having received any injury, and could not in any way account for his present trouble.

On examination, I found the left testicle very tender, quite tense, and swollen to about twice its normal size, with no evidence of the usual causes of this condition. My opinion at the time was that the patient must have had a mild attack of mumps, and that his present condition was the sequel. On the usual line of treatment he seemed to improve. Six days afterward the right testicle became swollen, much the same as the left one had been. This condition lasted for seven days, and the patient was feeling pretty well when he noticed a slight swelling below each ear, in the angle of the jaws, accompanied by considerable pain. The parotid glands became very much swollen, and the patient developed a classical case of mumps.

When I last saw him sixty days after the first symptom of orchitis appeared the testicles were nearly normal. Although he wore a suspensory, he felt that he could dispense with it.

Having excluded, so far as I knew, the ordinary causes of orchitis, with one testicle involved at a time, and the parotid glands becoming involved so soon after the orchitis, I arrived at the conclusion that the order of metastasis in mumps had been reversed in this case.

I have not been able to find a parallel case.

THE STIMULATION OF ADRENAL SECRETION BY EMOTIONAL EXCITEMENT*

W. B. CANNON, M.D., and D. DE LA PAZ
BOSTON

Dreyer's demonstration that splanchnic stimulation increased the content of epinephrin in blood from the adrenal veins has been confirmed by several observers Adrenal secretion therefore is under control of the sympathetic system.

Major emotional disturbances indicate the dominance of sympathetic impulses. In the cat, for example, fright causes dilatation of the pupils, inhibition of the stomach and intestines, rapid heart, and erection of the hairs of the back and tail. Do not the adrenal glands share in this wide-spread subjugation of the viscera to sympathetic control?

To try this suggestion the inhibition of contraction in strips of longitudinal intestinal muscle, sensitive to epinephrin 1 to 20,000,000, was used as a biologic test Blood was obtained from the cat when quiet, and *again* after the animal was excited by the presence of a barking dog, by introducing, through the femoral vein, into the inferior vena cava to the region of the liver, a small catheter lubricated with petrolatum. The blood thus obtained was defibrinated and applied to the intestinal strip at body temperature.

After an initial shortening the strip contracted rhythmically in blood from a quiet animal. In no instance did such blood produce inhibition. On the other hand, blood taken from animals after the emotional disturbance showed more or less promptly the typical relaxing effect. As the emotional period was prolonged, the effect became prompter and more profound.

The view that inhibition of the contracting intestinal strip is due to an increased epinephrin content is justified for the following reasons: 1. The effect was obtained in blood from the vena cava near the liver when that from the femoral vein taken simultaneously produced no inhibition. 2. Removal of the adrenal glands after tying the adrenal vessels resulted in a failure of excitement to produce the effect. 3. Adding varying amounts of adrenalin to inactive blood evoked all the degrees of relaxation that have been observed in excited blood. 4. Excited blood which produced prompt inhibition lost that power on standing or on being agitated by bubbling oxygen. These conditions, together with the evidence that sympathetic impulses increase the secretion of the adrenal glands, and that during such emotional excitement as was here employed signs of sympathetic discharges were observable in the animal from the eye to the tip of the tail, prove that the epinephrin effect was due to epinephrin.

Injected epinephrin is capable of inducing an atheromatous condition of the arterial wall in rabbits, especially in elderly individuals, and is also capable of evoking hyperglycemia with glycosuria. As Ascher has shown, by prolonged stimulation of the splanchnic nerves, prolonged secretion of epinephrin with maintained high blood-pressure can be produced. In the light of the results here reported the temptation is strong to suggest that some phases of these pathologic states are associated with the strenuous and exciting character of modern life acting through the adrenal glands. This suggestion, however, must be put to experimental test.

REPORT OF A CASE OF PARALYSIS OF THE BLADDER

ILLUSTRATING THE IMPORTANCE OF CATHETERIZATION BEFORE OPERATION

H. J. RELIHAN, M.D., AND J. SIMON, M.D.
SANBORN, IOWA

In this case of paralysis of the bladder the patient was operated on under the diagnosis of ovarian cyst with twisted pedicle complicated by pelvic infection. The condition followed normal labor and delivery, and shows the importance of catheterization before operation.

Patient.—Married woman, aged 30, mother of three normal children; previous history negative; in the second stage of labor when first seen. A normal living child was delivered without the use of forceps and without laceration of the mother's tissues. Delivery of the placenta was normal. For the first six days after delivery the patient's condition was normal. On the sixth day, the uterus was six finger's-breadths above the pubis. The urine was examined and found normal. The patient felt well. On the seventh day, the temperature was 102 F., and pulse was 120. The patient complained of great abdominal pain, more especially on the right side. The abdomen at this time began to distend rapidly and in size simulated a six-months' pregnancy. The bowels were regular and a normal amount of urine was being passed though there was some irritability of the bladder. On the eighth day, the temperature was 103 F. and the pulse 140 and poor in quality. All the symptoms pointed to puerperal sepsis except the distention of the abdomen, especially the lower part. Pain at this time was only controlled by administration of ¼ grain of morphin sulphate as necessary. By this time the size of the abdomen resembled a full term pregnancy.

Examination.—This showed great abdominal distention, especially in the lower portion. Percussion showed a cyst or watery tumor in the median line, especially in the pelvis. It seemed to be of great size and a diagnosis was made of ovarian cyst with twisted pedicle accompanied by pelvic infection, and immediate operation was advised.

Blood Examination: White cells, 18,000; red cells, 5,000,000; hemoglobin, 90 per cent. Differential count showed: small mononuclears, 18 per cent.; large mononuclears, 6 per cent.; eosinophils 2 per cent.; polymorphonuclears, 74 per cent.

Urine Examination: The urine was being passed every two to four hours in quantities of from 4 to 6 ounces. The reaction was alkaline. Otherwise it was normal.

Operation.—As the patient had been passing urine at regular intervals and had passed eight ounces just before the operation it was not thought necessary to catheterize her. An incision about 4 inches long was made in the median line. A large blue, thin-walled tumor presented which resembled in every way a cyst of ordinary character. A trocar was inserted and 3 gallons of urine were withdrawn. The fact that the tumor was not a cyst but the bladder was not recognized til lthe urine escaped through the trocar. The viscus was closed with No. 2 Chromic catgut, great care being exercised not to injure the mucosa. The abdominal incision was closed in the usual way and both wounds healed by primary union.

Postoperative History.—The ordinary treatment in any postoperative case was carried out, plus, of course, treatment of bladder symptoms. There was no complaint of pain. The patient was catheterized three hours after the operation and three times a day thereafter, the strictest antiseptic precautions being observed each time. After the fourth day, after the last catheterization of the day, a few drops of silver nitrate solution were left in the urethra. Hexamethylenamin (urotropin) was given regularly. On the fifth day as often happens after repeated catheterization, the bladder became infected. The patient had chills and the temperature rose from normal to 103 F.; the pulse was 138. The kidneys also became infected. Analysis of the urine showed: color, dark cloudy; specific gravity, 1026; sugar, negative; albumin, negative; indican, present; bile, negative. Microscopic examination showed many motile bacteria, numerous crystals (calcium oxalate), granular casts and blood-cells. There was also excess of mucous and triple phosphates. By the twelfth day the patient was in excellent condition and she was discharged well on the eighteenth day.

A CASE OF ENTERITIS FROM TRICHOCEPHALUS DISPAR

B. N. WADE, M.D.
CHICAGO

Patient.—An Austrian woman, aged 22, entered the Cook County hospital suffering from an intractable anemia and it was not until after her stools had been examined that the etiologic factor was discovered. She had lived in Boston until four months prior to admission. She had worked as a laundress; never used alcoholics; food was of poor quality; she ate in cheap restaurants. Fourteen months prior to admission the patient began to lose strength, and finally had to quit work; suffered with severe headaches, which were always in the occipital region. Her appetite was poor, and eating would nauseate her, and often caused vomiting, but she never vomited blood; had not vomited or even been nauseated for several months; the bowels had always been regular. The patient had had a slight bronchitis ever since the trouble began; had never been troubled with fainting spells or palpitation, although at times she became very weak and dizzy; on exertion, she would become short of breath. The patient had lost 50 pounds in weight. When the trouble first came on, the patient suffered a great deal from epistaxis, but had never lost any great amount of blood from this source; had complete amenorrhea since the beginning of the illness and during the time of the menstrual periods would often have nose-bleed. Previous to this the menstruation was normal. The patient stated that the muscles in her arms had pained ever since she took sick, and they were somewhat tender, and became stiff on exercising them. This myalgia was most severe at night. The patient also complained of a dull aching pain in the abdomen, especially in the splenic region, and said that it was always present; there was a drowsy feeling all the time. The patient had never felt this way until this trouble came on.

Physical Examination.—The patient appeared languid and apathetic; was pale and anemic; pulse and temperature were normal. The tongue was coated white, and the breath exceedingly foul. The chest and cardiovascular system were negative. There was some tenderness in the left epigastric region and over the descending colon; liver and spleen normal. On vaginal examination, there was extreme tenderness in the posterior fornix; rectum was somewhat tender. The stools were foul-smelling, greenish in color and watery in consistency. They contained many ova of the *Trichocephalus dispar*, which were of the characteristic brown oval forms with clear polar bodies. Each field contained four or five ova. After repeated examinations, the parasites themselves were found but once. There was no occult blood in the stools; small particles of undigested foods were present and mucus was also present to some extent.

Blood Examination.—Red cells, 3,100,000 per c.mm.; leukocytes, 8,300 per c.mm.; hemoglobin, 80 per cent. The differential count showed an eosinophilia of 10 per cent.; the other cells were present in about normal percentage.

The urine showed the presence of indican; otherwise it was normal. The stomach contents were also normal.

Treatment.—Two weeks after the patient was put on thymol, gr. 2, t. i. d., the ova completely disappeared from the stools. The bowels were kept open with calomel and Epsom salts, and an occasional colonic flushing was also given. The anemia was disappearing under the use of Fowler's solution and elixir, iron, quinin and strychnin.

My reasons for reporting this case are, first, to emphasize the importance of examination of the stools as a routine procedure, and especially in cases of anemia when no cause is evident; and second, because this is a disease which is either infrequent in this section, or one which is commonly overlooked.

Therapeutics

THE PROPHYLAXIS OF MEASLES

It is difficult to find either a physician or a layman to-day who has the temerity to expose a healthy child to contact with one who is suffering from scarlet fever, with the avowed object of infecting the healthy child. With measles it is different. Not a few non-professional people are inclined to advise, and even take pains to expose healthy children to infection from patients suffering from measles with the hope that the healthy children may contract the disease.

The circumstances connected with the two diseases are somewhat different. Scarlet fever, as has been pointed out in THE JOURNAL, is a disease to which not all persons are susceptible, a considerable number enjoying either an absolute immunity because they never contract the disease, or an immunity because they have already passed through the disease in so mild a form that it has not been recognized. Measles, on the other hand, is a disease to which practically every individual who has not already suffered an attack is susceptible. It is one of the most contagious of all diseases, ranking in this respect with small-pox and typhus (the genuine typhus, not typhoid) or ship fever.

It seems almost invariably true that one attack of the disease protects against subsequent attacks, though most writers teach that a second, third, and even fourth attack are not uncommon. It is probable that when these repeated attacks are alleged to have occurred, some of them at least were other cutaneous infectious diseases, especially so-called German measles, or some eruptive but non-contagious disease.

Many cases might be cited illustrative of these points, but only two or three will be mentioned here. The famous epidemic reported by Dr. Panum, the Danish physician, in the *Archives générales de médecine,* April, 1851, has been mentioned by numerous writers from Watson to Osler. This epidemic occurred in the Faröe Islands, in 1846. No measles had been known in this group of seventeen small islands since 1781 until on March 28, 1846, the disease was introduced by a man who had come from Copenhagen. In October of the same year the disease had entirely disappeared, and during the interval which had elapsed, of 7,782 inhabitants of the islands, 6,000 had had the disease; 1,500 persons who had established quarantine against the disease escaped.

In 1875, it is reported that measles was carried by a ship of the British navy from Sydney to the Fiji Islands, and in the succeeding epidemic 40,000 out of the 150,000 inhabitants died in four months. This shows the terrible severity of the disease in people who have no hereditary partial immunity.

In the Civil War, a large number of soldiers had measles, and many died from it. This disease occurred more frequently in the regiments which were recruited in the country towns than in those which were recruited in the large cities, this being explained by the fact that in country towns epidemics occur at longer intervals, so that a large number of boys reach manhood without having had the disease, while in the large cities epidemics are frequent and few boys grow to manhood without having experienced it.

These instances show that practically everyone is susceptible to measles until he has had it, and that an attack in adult life is generally more severe than in childhood.

Taking these facts into account one may well question first, whether it is possible entirely to prevent epidemics of measles; and second, whether, if it is possible to prevent them, it is desirable to do so?

On the other hand, it has been observed that children under six months of age are less likely to take this disease than older children, and that extremely old people are also less susceptible. Also, it seems to be a fact that the disease is most disastrous in its effects on infants, on children who have scrofulous glands, on persons who are tuberculous, or who have any tendency to tuberculosis, on individuals who are debilitated from any cause, and on women who are pregnant or who have recently been confined.

The above being true, it certainly can be reasonably asserted that the effort should be made to isolate children who are suffering from measles in order to prevent the spread of the disease, at least to people in whom an attack of the disease is likely to be followed by disastrous results. The details which should be carried out in order to accomplish this are not very different from those applicable to the prevention of scarlet fever, as given in THE JOURNAL, March 4, p. 667.

The contagious element of measles appears to have less vitality and to resist the ordinary measures of disinfection, including sunlight and fresh air, much less strongly than does the contagium of scarlet fever. The contagion of measles seems to exist very extensively in the secretions from the nose, throat and mouth, and the disease seems to be especially contagious during the period when the catarrhal symptoms are manifest, but before the cutaneous eruption appears. This increases the difficulty of enforcing efficient quarantine, for ordinarily, before the eruption appears, the child is believed to be suffering merely from a cold, and by the time the eruption appears and the quarantine is enforced many children have been exposed to the disease. When the disease is prevalent, children who show symptoms of a cold in the head should be suspected of perhaps having measles and should be promptly quarantined, but at the beginning of an epidemic it is rare that a child will be placed in quarantine before the eruption has appeared.

The general rule that well children should be kept apart from sick children is not usually followed with reference to children who are suffering from catarrhal affections of the nose and throat. When the rule is extended so as to apply to these patients, both whooping-cough and measles will be less rapidly passed around among the children.

The measures enumerated as applicable to scarlet fever and which are also applicable in cases of measles may be briefly summarized as follows:

The isolation of the patient in a remote room of the house.

The selection of a single immune person to care for the patient.

The wearing by the physician of a linen or rubber coat, when he visits the patient, which is removed outside of the patient's door.

The destruction of books and toys, which have been used by the patient, at the end of the period of quarantine.

The disinfection of dishes and clothing before they are removed from the sickroom.

At the end of the period of quarantine, which in the case of measles unattended by complications should be three weeks, the bathing and shampooing of the patient, and dressing him in fresh clothes.

The disinfection of the room, after it has been vacated, by the vapor of formaldehyd and by exposure of the room so far as possible to fresh air and sunshine.

The carrying out of these rules is a duty which every head of a family owes to the community, and especially to his neighbors who are at either extreme of life, or who are in delicate health. Such preventive measures should be enforced not only by the physician, but also by the sanitary authorities of the town.

As has just been said, sunshine and light are essential to the killing of the germs of all disease, and especially of measles; hence the room of a patient suffering from measles *should only rarely be kept dark during the day.* The patient's eyes may be efficiently protected from light by blue or smoked glasses.

The prolonged cough of measles after the period of quarantine is over should be treated as though the patient had incipient tuberculosis, and then the number of secondary deaths from measles will be cut in half.

OXYURIS VERMICULARIS: PIN-WORMS

The pin-worm, thread-worm, or seat-worm, as it is commonly known, is the most frequent intestinal parasite of man. It occurs frequently in children, but is also found in adults, in whom it may continue to cause the most annoying symptoms for a prolonged period.

The most common symptom is itching about the anus, which is due to the presence of the worm in this locality. It may, however, migrate to adjacent parts, causing also pruritus vulvæ which in turn may lead to masturbation. This itching comes on in the evening or at night after the patient has retired. It frequently causes restlessness and disturbance of sleep. It may interfere with the appetite and nutrition of the patient, causing anemia and emaciation. Less often it produces more serious nervous disturbances, and rarely even convulsions.

The male worm is smaller in size than the female, the latter being about three-quarters of an inch in length, and the male about one-fifth of an inch.

The eggs are taken into the mouth with the food or from the fingers which may become infected during the scratching caused by the itching. Passing into the stomach, the eggs hatch out and the worms develop and pass into the small intestine, and from there into the large intestine and rectum, where the female deposits its eggs in immense numbers, frequently passing out from the rectum to the anus for this purpose.

The treatment should be internal, local, and general. The internal treatment should be directed toward removing the parasite from the intestinal canal as rapidly as possible. For this purpose magnesium sulphate is perhaps the simplest remedy, and it is usually efficient. Calomel is preferred by some, and should be given in a good sized dose, as, for instance, 5 grains for an adult. Santonin has been recommended, but on account of its toxic effects should not be employed, except in obstinate cases.

The local treatment consists of rectal injections of various sorts. Water is very destructive to both the worms and the eggs, and in many cases copious injections of water are all that is necessary to effect a cure. Commonly recommended are infusions or decoctions of quassia, made by steeping one ounce of quassia, powdered or in chips, in one pint of hot water. When this has become cooled to the temperature of the body, a portion of it may be injected into the rectum and retained, if possible, for from ten minutes to half an hour. In many cases injections of warm soapsuds have proved efficacious. In cases which resist these remedies, a solution of the corrosive chlorid of mercury of the strength of 1 to 10,000 may be used. In using these injections it is necessary to inject as large an amount as can be retained with comfort. Young children cannot usually be expected to retain more than from 2 to 4 ounces. Adults can frequently readily retain from half a pint to a pint, especially if the hips are raised; or the patient may be given a colon wash. The larger injections are desirable in order to distend the rectum thoroughly and to remove the mucus in which the worms find an agreeable habitat.

If the itching and scratching about the anus have resulted in congestion and thickening of the skin, the subsequent itching may be irrespective of the presence of the parasite. For this condition the official unguentum phenolis (a 3-per cent. ointment of phenol) may be employed with benefit.

As the persistence of the parasite in the intestine is favored by an unhealthy condition of the mucous membrane, general treatment should be directed toward restoring the intestinal canal to a healthy condition.

The prophylactic treatment, which is of considerable importance, embraces frequent bathing of the parts with soap and water, thorough washing of the hands after they have been used in scratching or other manipulations, and boiling of the clothing and bed-clothing to destroy any eggs which may be deposited on them. The treatment with enemata should be repeated daily until the trouble is thoroughly removed. This can be definitely determined by microscopic examination of the feces, which should show entire absence of the ova.

Before the treatment of the individual patient is complete, inquiry should be made in regard to the presence of the parasites in other members of the family, including not only the children and parents, but also nurses and other attendants.

Essentials of the Campaign Against Tuberculosis.—Stating that tuberculosis is "a disgrace to our civilization," in a recent address Ex-Governor Charles E. Hughes of New York, now a justice of the Supreme Court of the United States, outlined the essentials of the work against tuberculosis. He said: "Here is a chance for the cooperation of all, no matter what their political views may be, no matter what their theories of government may be. I recognize the necessary limitations of governmental action. And here, not only must we have the action of government within its proper sphere, but this must be supplemented by the cooperation of those voluntary agencies which work outside the domain of government. Necessary information can be brought home to those who are in unfortunate circumstances which are remediable, so that they may know that the conditions may be a little less unfortunate by attention to a few simple rules with regard to hygiene and the proper ordering of life and its surroundings. Those who house other people and profess to have some patriotic pride in our institutions, can more clearly realize what they should do in the interest of the entire community in providing decent abodes for those from whom they take rent. Local authorities in our cities must appreciate the importance of securing prompt and full information in regard to cases and the faithful execution of our health laws so that this shall not be a paper program, but a realized advancement. In our counties the boards of supervisors are having opportunity, and should realize the necessity of improving conditions. This work must find its support in the sentiment of our communities. You cannot carry it by main strength against the will of the people. The people must be brought to realize what can be done, what is practicable, and support it because they understand it. Every man and every woman who knows the situation can be a conductor of electrical energy and give this movement its needed power."

SATURDAY, MARCH 11, 1911

INFECTION AND ANAPHYLAXIS

As a result of work on anaphylaxis, the belief is gaining ground that many of the toxic processes of infections are to be explained on this basis. Rosenau and Anderson,[1] among others, have shown that true anaphylaxis can be produced to bacteria as well as to other proteid-containing substances, and von Pirquet and Schick[2] some time since went so far as to conclude that "the pathogenic substance has *in itself no disease-producing effect*; but rather, the symptoms of disease appear only when changes effected in the pathogenic substance, by the host, have attained a certain degree." Needless to say, such infections as produce true toxins, as diphtheria and tetanus, do not come under consideration, and the theory is particularly applicable to those diseases in which we were formerly accustomed to assume the existence of bacterial endotoxins as the cause of the process. The essential difference from this latter view is the belief that the bacteria in themselves have little or no toxic effect; that this results from an interaction of bacterial proteid (antigen), antibody and complement, the two latter being contained in the serum of the host. In this way the assumption of specific bacterial toxins with every infection becomes unnecessary; and the failure to obtain antitoxins with so many microorganisms is readily explicable.

It is evident that the phenomena of an acute anaphylactic reaction—convulsions associated with air hunger—are rarely, if ever, those of an infection. But the much more gradual addition of the foreign material in the latter case affords a satisfactory explanation for this difference. Indeed, Friedberger,[3] by injecting sensitized animals with repeated small doses of the foreign proteid, was able to produce continuous and remittent and intermittent fevers, and he concludes that "anaphylaxis is an extreme and acute form of infection, and infection a milder, more protracted form of anaphylaxis."

Neufeld and Dold[4] *have taken up the problem of the* possible identity of bacteriolytic antibodies with those associated with the process of bacterial hypersensitization. In the case of the cholera vibrio, anaphylaxis occurred only when lysis of the organism by the immune serum was prevented by keeping the mixture of organism and sensitized serum at freezing temperature. When lysis was allowed to take place, the resulting mixture produced no acute toxic effects. With the pneumococcus, *on the other hand, there was no* bacteriolysis to be guarded against, and the anaphylactic reaction was obtained regardless of the temperature at which the mixture was kept. Solution of this organism by autolysis, or by chemical means, gave inactive mixtures. Hence it would appear not only that the antibodies associated with bacteriolysis and with anaphylaxis are distinct from each other, but that the one process places itself in direct opposition to the other. So that bacteriolysis acts to some extent as a protective measure against anaphylaxis; and in the case of a disease like *cholera, the clinical picture becomes the resultant* of two opposing forces—the bacteriolysis in part preventing acute anaphylactic intoxication, but meanwhile liberat*ing a noxious, but less acute endotoxin.*

It is of course obvious that diverse bacteria can produce similar clinical conditions depending largely on *the localization* of the infection. And the present theory, departing largely from the assumption of specific toxins for the different organisms, gives this an adequate explanation. The theory also explains nicely the incubation period of disease, as being the interval elapsing between the actual invasion by microorganisms and the formation of a sufficient quantity of antibody to produce the toxic effects resulting from the combination of antigen plus antibody.

SEX AND THE INSTRUCTION OF THE YOUNG

The attitude of the modern world toward the problem of sex, and especially of education in the hygiene and ethics of sex, seems an anomalous one. The subject has always been surrounded with mystery; but simpler and more primitive peoples find life full of mysteries, which they confront smiling and unabashed. We have few mysteries left to us; and the antiquated taboos which overshadow this one *appear scarcely sufficient to account* for the feeling, curiously compounded of dread, aversion and curiosity, which any discussion of the subject seems to arouse in most people to-day. The pagan world of antiquity frankly glorified sex, even in its sensual aspect; the asceticism of the middle ages rigorously condemned all aspects as sinful. The modern world professes to repudiate both doctrines; but the two seem to mingle in the ill-balanced and feverish sensitiveness on the subject often betrayed to-day, both in silence and in speech.

For a long time the outwardly predominating factor of asceticism has conspired with a host of shadowy, undefined motives to keep all enlightenment on the subject from the young with the same fearful zeal that guards a powder-magazine from sparks. Experience and observation have taught, however, that the dreaded explosive force in humanity is not, like the powder, dead until awakened by a spark from outside; rather it is like live steam, dangerous only if not provided with the proper outlet. The ban of silence has, therefore, been lifted, and organized effort has set unflinchingly about the task of revealing the consequences, frightful or loathsome though they may be, of transgressions against the hygiene and ethics of sex.

[2] Wiener klin. Wchnschr., 1903, xvi, 758.
[3] Berl. klin. Wchnschr., 1910, xlvii, 1922.
[4] Berl. klin. Wchnschr., 1911, xlviii, 55

Even yet, however, the ascetic view predominates; the destructive aspects of this ever-present natural force are the ones emphasized. That impulse which the Greek saw as a part of the vivifying forces of an august yet genial Nature, typified by the fertile earth and the quickening rain and sunshine—that impulse which has directly inspired much, if not most, of the greatest efforts in all forms of art, and which in subtler ways has entered into the greatest achievements of humanity—that impulse which, after all, not only perpetuates, but forever binds together the race with ties growing out of family, kinship and friendship—that impulse is presented to the impressionable mind of youth chiefly in its perverted aspects—aspects which shock and repel. Is there danger of permanently distorting the point of view—of infecting the susceptible youthful mind with suspicion and pessimism and, indeed, of actually degrading its ideals and possibilities?

This question has been stated clearly, forcibly and thoughtfully by W. D. Parkinson.[1] "The merit of truth," he says, "is not in its nakedness. To depict in startling colors the awful consequences of vice and to dwell on its equally appalling prevalence have never been found effective in advancing the standards of virtue. Indeed, these are the very measures oftenest employed by the two most active promoters of vice—the quack who deals in startling consequences and the evil companion who is always ready with the assurance, 'They all do it.' . . . Fear of consequences is not the ultimate appeal to a robust nature. No degree of danger will deter a youth from venturing into experiences which he believes he is to share with those who constitute the real world: and vice always claims to be the real side of human life. . . . Society is so permeated with this tone of patronage toward the poor fellow who has not sown and reaped wild oats that no threatened consequences can avail much with a youth who would rather be penalized than patronized. The half-contemptuous attitude toward innocence, maintained so conspicuously by the more outspoken portion of the public, is more impressive to the average youth than all the scareheads that benevolence may display in his path. For every man desires to be a sharer with other men. Unless he can be assured that reality reaches as far upward as it does downward, that the upper world is as rich to the explorer as the nether and affords at least equal manly companionship, he will cast in his lot with the underworld and take his chances with his fellows in spite of all warnings."

This touches the root of the matter. The negative sanctity of the ascetic—the insulated safety of the anchorite—make no appeal to most young people, and especially to boys, who look forward to living in a "man's world." Warning alone is not likely to save any but the weaklings, if indeed it saves them. The salvation of more robust natures must be positive. There is much wisdom, therefore, in Mr. Parkinson's assertion that the sex relationship should not be presented either as a menace in itself or as a mere matter of personal or social hygiene, but as "one of the fundamental—perhaps the most fundamental—of all the factors of social and spiritual progress." His article is worth reading, and his conclusions are worth pondering over.

THE LENTICULAR ZONE AND ANARTHRIA

The aphasia storm which had its origin in the "Revision" paper of Marie in 1906, and which broke with such violence in the discussion before the French neurologic society in 1908, has now almost passed, leaving the situation somewhat clearer, but still possessing most of its ancient landmarks.

It will be recalled that Marie maintains that Broca's convolution plays no rôle whatever in the zone of language; that aphasia is always due to a lesion of Wernicke's zone, and is always the "sensory aphasia" of the classical adherents; and that a lesion of the lenticular zone, of which he makes a tentative description, produces an anarthria—which anarthria plus the sensory aphasia equals the classical Broca's aphasia.

Thus: An isolated lesion of the zone of Wernicke=aphasia of Wernicke; an isolated lesion of the lenticular zone=anarthria; a lesion of the two zones=aphasia of Broca.

Dejerine stood by the classical conceptions, as did also Liepmann, Ziehen, Bianchi, Grasset and a host of others; v. Monakow took a median position, while Marie, Souques, Moutier and others defended the new theses in whole or in part.

It soon became evident that Marie's first contention was false. It has been proved without doubt that Broca's convolutions do play an important rôle in the function of language. The second contention never contained anything particularly new, save the added claim made by Marie that there was always an intelligence defect involved in Wernicke's aphasia; this has been effectually disproved by a number of recent studies. Now Mahaim[1] and Van Gehuchten[2] enter the lists and show that lesions of the left lenticular zone in right-handed individuals may occur without anarthria—in fact, without any trouble with speech whatever.

---

[1] Parkinson, William D.: Sex and Education, Educational Rev., January, 1911, p. 42.

[1] Mahaim: Un cas d'aphasie motrice et sensorielle sans hémiplégie, avec intégrité de l'opercule, de l'insula, et du noyau lenticulaire, Bull. de l'Acad. roy. de méd. de Belgique, December, 1909, and Feb 27, 1910.

[2] Van Gehuchten: Lésion de la zone lenticulaire gauche sans troubles de la parole, Le Névraxe, Dec. 20, 1910.

Both Mahaim and Van Gehuchten have studied cases by means of serial microscopic sections in which the "lenticular zone," as described by Marie, has suffered almost total destruction, and yet there have been no speech disturbances of any kind. Furthermore, Van Gehuchten analyzes in detail the proofs advanced by Moutier in his thesis on which Marie bases his contentions, reproducing all his pictures, and shows that Marie's anarthria is really an anarthria of projection.

Thus, while aphasias still need more extended study by serial microscopic sections in order to clear up many vexed points regarding the rôle played by a number of projection and association paths in the function of language, it would appear that the final *coup de grâce* has been given to the last of Marie's primary contentions in his initial famous "Revision."

THE CIRCULAR AROUND THE BOTTLE

The Council on Pharmacy and Chemistry has certain rules governing the admission of proprietary and other medicinal products to New and Nonofficial Remedies (N. N. R.). A large number of preparations are ineligible to N. N. R. because they are exploited in nonconformity with Rule 4, which reads:

> "*Indirect Advertising.*—No article will be admitted whose label, package or circular accompanying the package contains the names of diseases, in the treatment of which the article is said to be indicated. The therapeutic indications, properties and doses may be stated. (This rule does not apply to circulars, etc., when distributed solely to physicians, to advertising in medical journals, or to vaccines and antitoxins.)"

In other words it is held that circulars describing the diseases in which the remedy is useful are distinctly detrimental to public health; the tendency always is to exaggeration, not only as to their value, but also as to the variety of diseases in which the remedy is indicated.

A considerable proportion of the medical profession may still be charged with heedlessly playing into the hands of the "patent-medicine" man. The "circular around the bottle" is a striking instance of this. The patient has placed in his hands a preparation in the "original bottle" wrapped around which is a circular containing a comprehensive list of all the ills and pains and various derangements for which that product is supposed to be valuable. He is also given with the same package a supplementary list of a dozen or so of other prescriptions, and what diseases they will cure. He is at once advised how he may at all times and of his own initiative obtain these wonderful remedies. And all this with the (presumed) full endorsement of the family physician! Could anyone devise or imagine a more effective way of starting a patient on the road to self-drugging? And is not this the nature and purpose of the fanciful "circular around the bottle?" There are dozens, probably scores, of preparations which have never been advertised directly to the public and yet which are bought by that public, over the drug store counter, like the rankest of "patent medicines." These self-druggers have been made such by the carelessness of physicians who have prescribed "original packages" of such proprietaries as those under discussion. It is necessary only to call to mind such preparations as Antikamnia, Micajah's Wafers and Glycothymoline as some of the most flagrant examples, to realize the evil of prescribing a product having a "*circular around the bottle.*"

Nevertheless, the Council has been assured by several manufacturers that their preparations would be unsalable if they omitted this circular; that physicians would not use or prescribe these preparations without the circular, and—the saddest part of it all—these manufacturers appear to be serious and honest in their contention. What is the *meaning?* Do physicians really need the circular around the package or bottle to tell them why they are using this or that drug? Or does the circular confer some peculiar potency on the drug which would be lost if the circular were omitted? Or is the circular one of those bad but seductive habits which we would rather suffer than do without? Or, finally, are these manufacturers mistaken in their estimate of what physicians really want?

THE SECRET COMMISSION EVIL

The giving and receiving of secret commissions has been discussed with increasing frequency for several years. Although the existence of this practice has long been recognized, we have always believed that it has been confined to a comparatively small number of physicians. Condemnation of this evil by the Association, by THE JOURNAL and by various medical societies, as well as occasional local investigations and exposures, have apparently failed to abolish it. Recent discussion shows that the better men in the profession appreciate the importance of the problem and the need of its solution by physicians. In this issue appear two articles on the subject, one the president's address before the Western Surgical Association,[1] and the other an editorial from *Colorado Medicine*.[2] Both of these articles are severe and carry the impression that the practice is widespread. We are loath to believe that conditions are as bad as represented. Yet this evil, if existent to any extent, should be freely discussed and unsparingly condemned. Its correction is of vital importance to the public as well as to physicians. While it has long been recognized as existent by the profession, the rapidly growing interest of the public in professional matters and the increasing disposition of physicians to take the people into their confidence, have apprised the public, apparently for the first time, of the existence of this condition. Now that the people are informed, the evil must be speedily corrected by the profession, for if it is not, the people themselves will demand the right to suppress it.

---

[1] THE JOURNAL A. M. A., this issue, page 725.

[2] Colorado Medicine, February, 1911; see THE JOURNAL, this issue, page 770.

It is significant that, in spite of the specious arguments brought forward in defense of this practice in professional circles, nö one has attempted to defend it before the public. The misleading excuses of "paying the attending physician for his time," "recognizing the diagnosis as of equal value with the operation," and other fallacious arguments which have been advanced in extenuation of this practice, will count for nothing with the public. Logically, they belong in the same category as the "poor boy" excuse for cheap medical colleges and night schools. Popularly, they will have much less weight, since the layman does not recognize, as yet, the importance of medical education to him and to his family, but does see, in the secret payment of commissions, that the patient, instead of being a sacred trust, is made an article of merchandise, whose money is divided without his knowledge.

The issue is so plain that it needs only to be stated to carry conviction to the unprofessional mind. It has been condemned and denounced repeatedly by medical organs and organizations and by high-minded medical men everywhere. Yet, we are told, the evil exists and is becoming more prevalent. If this be true, there is but one remedy, the remedy which in recent years has corrected many other pernicious and secret practices: Graft in the medical profession must receive the same treatment as graft in politics or in business—publicity. If the people and the profession are given the names of surgeons and specialists who offer secret commissions and of physicians who accept them, this wretched business will soon come to an end.

Apparently there is one community in which this remedy is to be applied. The Denver *Times*, an evening paper, which has for a long time excluded all objectionable medical advertisements, says editorially in a recent issue:

> . . . It is disquieting to learn from the organ of the Medical Society of Colorado that many physicians and surgeons are commercializing their practice through that system of secret rebates known as "fee-splitting." The method is about as follows: A patient consults a physician. The physician discovers that the case calls for the knowledge of a specialist or operation by a surgeon. Ethically it is the duty of the physician to seek the services of the most highly qualified man. But the sight of some possible dollars blinds the vision to ethical considerations and the patient is sent to the specialist or surgeon who agrees to pay to the physician the largest percentage of his fee. It is a debasing custom of course; it admits of neither extenuation nor excuse; but it seems to be a custom to which numerous physicians and surgeons of repute are addicted, and we believe that it can only be abolished by the publication of the names of the men practicing it. Some of those names we have obtained and authenticated already; we are investigating others now; and when the list is tolerably complete we will print it and gladly face the libel suits that such publication may involve. The men who do this kind of thing are well known already to the men who do not; in professional circles their names are a matter of common gossip; but they should be known equally well by the lay public, and we hope, shortly, to be able to give them the kind of advertising they merit.

And yet in this question, as in other complicated social problems, the public itself is to a certain extent to blame for existing conditions. In the majority of communities, the family physician is to-day receiving the same compensation which was paid his professional forefathers two or three generations ago; and this in spite of the enormous increase of the cost of professional education and of the standard of living, as well as of the quality of medical services. Whether wisely or not, the physician fears in many cases to raise the price of his services or to charge on any other basis than the time-honored, but economically absurd, basis of the number of calls made on the patient. The result is that in many cases the patient pays willingly and promptly the large fee demanded by the surgeon, but settles his bill with his family physician grudgingly and after long delay. The family physician often gives far more in time and services to the patient than he can expect to receive compensation for; and he has consequently turned to the surgeon to receive as a gift what he should have received from the patient as a right. If the public will compensate the family physician fairly and promptly for his services and will insist that all transactions between the physician and the consultant be carried on with the full knowledge of the patient, the cause and the possibility of this evil will speedily disappear. Physicians and surgeons must recognize the existence of this evil, must admit the rights of the public in the matter and must lead the way in abolishing it, but the public, on its part, must recognize the conditions which have given rise to this problem, must do its share to help the profession to solve it; and must support the family physician, both financially and morally, so that he may be able to deal honestly and fairly with his patients.

Current Comment

THE COST OF CLEAN MILK

On the principle that one cannot get something for nothing, it must be conceded that one result of the requirements for a cleaner, purer milk-supply will be an increase in its cost to the consumer. Official recognition of this fact is found in the report of the Philadelphia Milk Commission which recently investigated the matter of the milk-supply of that city. This report seems to cover fully the production and distribution of milk in all their phases, as relates to Philadelphia. The commission believes that milk can be produced and distributed under proper regulations with fair profit to all concerned at an advance of one cent a quart over present prices, making the price nine cents. They say that "the public is fully awakened to the danger of milk as received to-day, and will accept a proper increase in price to secure the protection that proper regulations will give them." They believe that though this might seem to be hard on the poorer consumers, really they will be most benefited, as at present they receive much milk that is unfit for consumption, and the amount which they will save by decreased illness on account of having a healthful milk-supply will more than compensate for the increased cost. They recommend that this increase should go to the farmers, who should receive not less than five cents a quart for milk produced under proper conditions. To this allotment, of course, the milk distributors demur. It is probable that the objection of the consumer to an increase in the price of milk has hitherto been because it benefited only the distributor, who already received the larger share of the selling price, for the smaller share of the labor and expense. The findings of the Philadelphia commission will no doubt apply, with modifications, to the milk question elsewhere, and their conclusions that the farmer should get more, and that the consumer will be willing to pay more, for clean, safe milk, will be generally accepted.

PLAGUE IN CHINA

Dr. Mullowney's account in this issue of the plague in North China illustrates one disadvantage of western civilization superimposed on a somewhat unprepared eastern population. The spread of plague would probably have been much less rapid in that section, as has been the case in the Hunan province in the south, had it not been for the existence of railroad communication. This, together with the insanitary conditions existing in the Chinese cities, and the unreadiness of the government to cope with the epidemic, make the condition there a very serious one. An infection like plague may readily spread along the main arteries of communication that have been opened up in such a country as China. The disease has continued to spread in many provinces, according to reports later than that of Dr. Mullowney, and probably will die out only after it has exhausted the susceptible material. Famine and rioting are adding to the horror of the situation and the extent of the devastation cannot be predicted. The "yellow peril" with this complication is a very real one and may be a matter of international concern at any time.

EASY WRITING VERSUS EASY READING: A HINT TO AUTHORS

The considerable amount of work required of the editor in preparing manuscripts for publication has led the editor of the *Journal of the Indiana State Medical Association* to voice a protest against the carelessness of authors in sending in their papers. The indictment is a true one. Writers could relieve the editor of much unnecessary work by a little care; and since, after all, no one should be so competent to set forth a man's own ideas and experiences as himself, such care would result in a better presentation of the subject than can be given by the most careful reviser. We refer particularly to case-reports, which are often presented in varying degrees of unprintable condition, sometimes being sprinkled with abbreviations devised by and intelligible only to the author, and sometimes merely defiant of grammar and syntax, but frequently requiring what amounts practically to rewriting. It would seem that the reports usually consist of disjointed, fragmentary notes jotted down at the time of examination, without revision, with verbs omitted from sentences, words, clauses and phrases separated by periods, the whole sounding like a telegram, with every rule of construction and punctuation violated. It would be no more difficult to make case-report a plain, consecutive narrative, conformin to the rules of good style, than to write the remainin text of the article in the same manner. The little tim required would be well spent, for the "easy writing which, as Byron said, "makes d—d hard reading, might almost as well not be done at all. We endors the sentiments of the editor from Indiana.

Medical News

ALABAMA

Tuberculosis Ward Equipped.—W. E. Colwell, Birminghan has donated equipment for a ward in the new sanatoriun established at Red Mountain by the Birmingham Antituberculosis Society. Ten of the twelve rooms have already bee furnished and the patients were removed to the institutio last week.

Society Elections.—Dale County Medical Society held it annual meeting in Ozark, January 11, and elected the following officers: president, Dr. Robert D. Reynolds, Jr., Ozark vice-president and censor, Dr. Andrew J. Morris, Newton; secretary-treasurer, Dr. M. O. Grace, Ozark; censors, Drs. Erastu B. Ard, Ozark; Samuel M. C. Howell, Midland City; Williar D. Mixson, Ozark, and Henderson L. Holman, Ozark; count health officer for four years, Dr. Erastus B. Ard, Ozark health officer for Ozark, Dr. M. O. Grace; for Midland City Dr. Samuel M. C. Howell; for Pinckard, Dr. R. G. Cary; fc Newton, Dr. James E. Stokes, and for Ariton, Dr. C. R. Athey ——At the annual meeting of the *Barbour County Medic* Society held in Eufaula, the following officers were elected president, Dr. John S. Tillman, Clio; vice-president, Dr Benjamin F. Jackson, Clayton; secretary-treasurer, Dr. William P. McDowell, Eufaula; county health officer, Dr. Clarenc Long, Comer; county physician, Dr. James J. Winn, Clayto and councilor, Dr. Benjamin F. Bennett, Louisville.——Coos County Medical Society has elected the following officers president, Dr. Julius Jones, Rockford; vice-president, Dr. S. I Jones, Rockford; health officer for five years, Dr. William I Moon, Goodwater, and censor, Dr. Eugene Argo, Goodwater.

CALIFORNIA

Additional Gift to Hospital.—Mrs. Whitelaw Reid has give an additional $60,000 to the Red Cross Guild Hospital, Sa Mateo, which was erected as a memorial to her parents, M and Mrs. D. O. Mills.

Election.—At the annual meeting of the Humboldt Count Medical Society, held at Sequoia, the following officers wer elected: president, Dr. John N. Chain, Eureka; secretary, Dr John M. Mill, Arcata; and treasurer, Dr. Francis R. Hore Arcata.

Dr. Royer is Not Dead.—In the *Southern California Practitioner*, December, 1910, appeared the death notice of Dr Daniel Franklin Royer of Orange, and on this authority hi name was included among the dead in this journal. Dr. Id B. Parker of Orange informs us that the notice was incorrect and that Dr. Royer is alive.

COLORADO

Commissioners Approve Dr. Cassidy's Plan.—The board c commissioners of Denver County, on February 9, placed itse on record as favoring Dr. Elizabeth Cassidy's move for mor careful selection of the medical staff of the city and count hospital, by adopting resolutions endorsing the provisions o the bill now in the hands of committees in the house an senate, which place the appointive power in the faculty of th state university, medical department.

Personal.—Dr. Leonard Freeman, Denver, who was recentl operated on for appendicitis at *St. Joseph's Hospital*, i reported to be convalescent.——Drs. Henry W. Hoagland, P Oliver Hanford and Gerald B. Webb, Colorado Springs, hav been appointed to the medical staff of Sunny Rest Sanatorium.——Dr. James C. Todd, Denver, has been appointed professor of pathology and secretary of the first and second year divisions of the University of Colorado Medical School, Boulder.

GEORGIA

New Officers for Medical Board.—At the February meeting of the medical board of Grady Hospital, Atlanta, the following officers were elected: president, Dr. John C. Olmstead; vice-president, Dr. F. Phinizy Calhoun; and treasurer, Dr. L. Benjamin Clarke.

Long Memorial Infirmary.—Crawford W. Long Infirmary banks were opened at various places in Athens, March 2. These take the place of a personal canvass for the establishment and endowment of a Memorial Infirmary for the University of Georgia in honor of the late Dr. Crawford W. Long.

District Society Election.—At the fourth annual meeting of the Tenth District Medical Society, held in Augusta, February 14, the following officers were elected: president, Dr. Joshua R. Beall, Blythe; vice-president, Dr. William W. Beattey, Jr., Augusta; and secretary-treasurer, Dr. George A. Taylor, Augusta (reelected). The society was entertained at a banquet by the Richmond County Medical Society in the evening, when addresses were made by Dr. Joseph N. McCormack, Bowling Green, Ky.; Dr. Albert Vanderveer, Albany N. Y., and others. The society adopted a resolution highly commending the faculty of the medical college for its efforts in behalf and in connection with the college-hospital movement.——The annual meeting of the Fourth District Medical Society was held in Carrollton, February 21. Addresses were made by Dr. Joseph N. McCormack, Bowling Green, Ky., and Dr. Eduard C. Davis, Atlanta, president of the Medical Association of Georgia. The following officers were elected: president, Dr. Charles A. Dexter, Columbus; vice-president, Dr H. J Goodwyn, Roopville; and secretary-treasurer, Dr. Homer Boatright, Carrollton. The next meeting of the society will be held in Greenville, September 19.

ILLINOIS

Maternity Hospital for Aurora.—The Sisters of Mercy announce that they have purchased the Ryburn Flats, with the surrounding property, for $18,000, and will establish a maternity hospital to be known as St. Joseph's Infirmary.

Hospital Staff Resigns.—Fifteen of the eighteen members of the medical staff of Oak Park Hospital resigned March 3, the cause assigned being the interference with the duties of the staff, by the Sisters of Misericordia, who are in charge of the hospital.

Personal.—Dr. Jesse M. Threadgill, New Douglas, was recently operated on in Rebecca Hospital, St. Louis, for a ununited fracture of the arm, due to a runaway accident, January 30.——Dr. Paschall N. Bowman, Springfield, charged with manslaughter, is said to have been freed from that charge, February 27, and committed to the Jacksonville State Hospital.——Dr. Lucinda H. Corr, Carlinville, was awarded $1,000 in her suit for damages against the Chicago and Alton Railway, for injuries received in a wreck.

Commend Association for Education Work.—The Williamson County Medical Society, at a special meeting held for the purpose, February 28, passed resolutions commending the American Medical Association for its services in elevating American medical standards and urging further effort until standards of preliminary education and of medical practice in the United States shall be fully equal to those of Europe. The preambles recite that there are many unnecessary medical colleges which are run for commercial purposes, and that, because of competition between these colleges, many incompetent and even illiterate physicians are graduated; and that these factors together with commercialism in professorships and lack of stringency in examinations are causing harm to the general practitioner, without any benefit to the public.

Chicago

Money for Sanatorium.—In the state tax levy for 1911 is included an item of $442,184.64 for the Municipal Tuberculosis Sanatorium.

Many Appointments to Medical Reserve Corps.—The President has sent to the Senate the nominations of sixty-seven more physicians of Chicago as first lieutenants of the Medical Reserve Corps.

Site for Tuberculosis Sanatorium.—The city of Chicago has taken title to the remaining 60 acres of the 160-acre tract purchased for the Municipal Tuberculosis Sanatorium at North Fortieth and Bryn Mawr avenues.

Trouble at Hospital.—As a result, it is said, of disloyalty and insubordination on the part of members of the staff of Mary Thompson Hospital, seven members have been dismissed. The physicians in question claim that the trouble lies in the appointment of a lay superintendent, and in the overbearing treatment of the physicians by the superintendent.

Personal.—Dr. David J. Davis of the Memorial Institute for Infectious Diseases has been appointed pathologist to St. Luke's Hospital.——Dr. Katherine B. Rich has been appointed assistant city physician, and began her duties February 24.——Dr. B. Brindley Eads, who was operated on at the Presbyterian Hospital, March 6, is making satisfactory progress toward recovery.

Society to Support State Institution.—The council of the Chicago Medical Society, at a meeting February 14, unanimously adopted resolutions endorsing the request of the trustees of the University of Illinois for an annual appropriation of $100,000 for the equipment, maintenance and extension of the medical school, and appointed a committee to assist in presenting the matter to the legislature and the governor.

Contagious Disease Hospital.—The common council has decided to add the fund of $75,000 bequeathed to the city by the late Mrs. Annie C. Durand for the establishment of a public bathhouse, to another fund, the combined fund amounting to about $200,000, to be used for the construction of a hospital for the treatment of contagious diseases, and an arrangement has been made with the trustees of the McCormick Memorial Institute for Infectious Diseases, whereby that institution will meet any expense of maintenance not covered by the Durand endowment fund.

To Avoid Undesirable Newspaper Publicity.—At its last meeting, the Council of the Chicago Medical Society adopted certain preambles and resolutions relative to newspaper publicity. The Council expressed the opinion that reporters should be excluded from all meetings of medical societies during the consideration of all strictly scientific matters, except those bearing on sanitation, public policy, hygiene or sociology; also that abstracts of such papers that come within the range of subjects considered as proper for publication in the public press be handed to the secretary, before or at the meeting, to be given by him to the press.

INDIANA

Contract for Hospital Let.—The contract for the erection of the new St. Vincent's Hospital, Indianapolis, was let March 2. The main building will be five stories in height and of steel, fire-proof construction. There will be two diet kitchens on each floor, and there will be fourteen operating rooms in the building, the entire top floor being given up to surgical purposes.

Leaves Estate to Hospital.—Hon. David Darwin Dykeman has left the bulk of his estate for the establishment of a city hospital in Logansport, to be known as the Mary Dykeman Memorial Hospital, to be in charge of a hospital commission to be composed of three members, one to be elected by the city council, one by the commissioners of Cass County, and one by the circuit court judge.

Twin City Physicians Meet.—A meeting was called in Indiana Harbor, February 21, which was attended by most of the physicians of that place and East Chicago. The object of the organization, which is to meet semi-monthly, is to establish a schedule of fees and to promote a more friendly feeling among physicians of the twin cities. Dr. George Orf, Indiana Harbor, was elected president of the new organization.

Personal.—Dr. Edward J. McOscar, Fort Wayne, has returned from a trip to Panama and Central America.——Dr. Matthias Muhlhausen, Evansville, is reported to be critically ill.——Dr. Orange G. Pfaff, Indianapolis, who has been seriously ill with septicemia due to an operation wound, is convalescent.——Dr. William H. Williams, Dale, has retired from the practice of medicine.——Dr. Walter M. McGaughey, Greencastle, sustained a fracture of the arm, February 16, by back-fire of his automobile.——Dr. Charles W. Corey, Hartford City, dislocated his left arm in an automobile accident, February 14.——Dr. Alfred Henry has been appointed chief of the Free Tuberculosis Clinic, Indianapolis, vice Dr. William T. S. Dodds.——Dr. Walter H. Peters, Lafayette, who was operated on recently in Rochester, Minn., is reported to be convalescent.——Dr. Abraham G. Shortle, formerly of Indianapolis, has been appointed medical director of the Albuquerque (N. Mex.) Sanatorium.——Dr. William H. McClurg, Kokomo, while crossing a railroad track recently, was struck by a passing train but was not seriously injured.

KENTUCKY

Sanitary School Incorporated.—The Louisville School of Sanitary Instruction has been incorporated by Drs. W. E. Grant, Ezra O. Witherspoon and William E. Gary.

Gift to Hospital.—The Jewish Hospital Association, Louisville, has received as a gift from Mr. Bernard Bernheim 70 feet of ground on Kentucky Street, adjacent to the hospital, which is valued at more than $10,000. The property includes a new two-story brick residence. The house is to be used as a nurses' home, and is to be called the Bernard Bernheim *Annex.*

Want Public Abattoir.—Dr. W. Ed Grant, city health officer of Louisville, has called a conference of all the butchers in the city to discuss the establishment of a public abattoir to cost in the neighborhood of $150,000. A joint investigation by the City Health Office and the State Pure Food Department has shown the slaughterhouses in the city of Louisville to be in a very insanitary condition.

Care of the Insane.—At the recent meeting of the State Board of Control of Charitable Institutions, a special committee of the State Federation of Women's Clubs advocated training school for nurses and attendants in state asylums for the insane, shorter hours of work and living rooms apart from those of the patients. At this meeting it was pointed out that there is no great need for an increased per capita allowance for the care of the insane, and it was also suggested that the names of the state asylums be changed to "state hospitals."

MAINE

Appeal for Bowdoin.—The president of Bowdoin College has issued an appeal to the alumni association for $140,000 for the use of the medical department. The most pressing needs of the institution are new laboratories and improvements and hospital facilities for the establishment of a dispensary in Portland.

Society Meetings.—York County Medical Society, at its annual meeting, held in Biddeford, elected Dr. Fritz E. Small, Biddeford, president; Dr. Eduard C. Cook, York Village, vice-president; Dr. David E. Dolloff, Biddeford, secretary; Dr. Lawrence E. Willard, Saco, treasurer; Dr. Frank H. Hobbs, Waterboro, censor.——Kennebec County Medical Association, at its annual meeting in Bangor elected Dr. Richard H. Stubbs, Augusta, president; Dr. Donald B. Cragin, Waterville, vice-president; and Dr. Wellington Johnson, Augusta, secretary-treasurer.——At the annual meeting of Androscoggin County Medical Association, held in Lewiston, the following officers were elected: president, Dr. Alonzo M. Gracelon, Lewiston; vice-president, Dr. Louis C. Baribault, Lewiston; secretary-treasurer, Dr. Joseph W. Scannell, Lewiston; and censors, Drs. Laureat P. Ducharme, Ernest V. Call, and Harold E. E. Stevens, all of Lewiston.——Portland Medical Club, at its annual meeting, elected the following officers: president, Dr. Ambrose H. Weeks; vice-presidents, Drs. Daniel Driscoll and Harold A. Pingree; secretary-treasurer Dr. Harold J. Everett; and censors, Drs. Bertrand F. Dunn, and Thomas J. Burrage.

MARYLAND

State Society Meeting.—The annual meeting of the Medical and Chirurgical Faculty of Maryland will be held in Baltimore, April 26-28, inclusive.

Personal.—Dr. Henry P. Fahrney has been appointed physician of Montevue Hospital, Frederick.——Dr. Daniel S. Jenifer, formerly of Atlantic City, N. J., has begun practice in Towson.

Increase Capacity of Sanatorium.—A new administration building and two additional hospital wings will be erected at the Maryland Tuberculosis Sanatorium, Sabillasville, this spring, increasing the accommodation for patients from 200 to 400. The new building will be about 500 feet in length and two stories in height.

Baltimore

Enlarge Dispensary.—The directors of the Baltimore General Dispensary have purchased a site 25 by 61 feet and will erect on it a two-story and basement building.

Personal.—Dr. Arthur Marriott was seriously injured by the bite of a baboon which escaped from its cage at the Custom House, February 28.——Dr. Covington has resigned as a member of the staff of the Presbyterian Eye, Ear, Nose and Throat Hospital.

Gift to Children's Hospital.—Dr. James Lawrence Kernan has given to the Kernan Hospital and Industrial School for Children a further gift of $10,000, which will be applied to the building fund. The previous gift included a large colonial house and 60 acres of land.

Fined Under Drug Law.—Dr. John F. Lang, is reported t have pleaded guilty in the criminal court, March 2, to fou indictments, charging him with unlawfully issuing prescriptions for morphin and cocain to habitual users of these drug and to have been fined $50 and costs in each case, making total of more than $300.

The Diphtheria Situation.—*As the result of the conferenc between the health department and medical staff of John* Hopkins Hospital, a canvas of boarding houses in whic students of the medical school live, was begun February 2 to determine the presence or absence of diphtheria. The cit was divided into four groups and eight employees of th health department and four members of the hospital sta were detailed on this work. About 175 homes were visite and 1,700 cultures made. The total number of cases c diphtheria in the hospital up to March 4, was fifty-nin including three physicians. There are also five cases of diphtheria at the Church Home. The dispensary has been close to all cases except those of throat trouble. The office o the medical school and postoffice have been moved to the hous adjoining the hospital. The Hebrew Hospital and Dispensar nearly opposite Johns Hopkins Hospital was closed to visitor and new patients, February 28, on account of the prevalanc of the disease in that section. For the same reason all visitors have been forbidden entrance to St. Joseph's Home fo Incurables, the Maryland Home and Hospital, and St. Agnes Hospital. Visitors are also prohibited at Mercy Hospita Maryland General and University Hospital. Dr. J. Whitridg Williams, dean of Johns Hopkins Medical School, has announce the resumption of first and second year work, March 8, bu throat cultures are made before admission of students.

MASSACHUSETTS

Illegal Practitioner Fined.—Edward E. Hosmer, Lynn, wh burned several children with a powerful acid in an effort t cure infantile paralysis, is said to have been found guilty o practicing medicine without a license, and to have been fine $250, February 25.

Society Meeting.—The Eastern Hampden Medical Societ at its thirty-first annual meeting, February 9, in Springfiel elected Dr. Albert M. Belden, Northampton, president; D Arthur L. Damon, North Wilbraham, vice-president, and D Raymond A. Kinloch, Springfield, secretary-treasurer.

Money for Hospitals.—By the will of the late Mrs. Ros Cobb Cole, Plymouth, $100,000 is devised to the Jordan Hospital in that city.——By the will of ex-mayor George W Fifield, Lowell, $20,000 is devised to St. John's Hospital Lowell, and a similar amount to the Lowell General Hospital

NEBRASKA

Personal.—Dr. Adolph Sachs, Omaha, has returned from Europe.——Dr. Frank M. Barnes, Omaha, was struck by a automobile, February 21, spraining his ankle.

Change of Staff of State Hospital.—On February 2, Dr William B. Kern succeeded Dr. Mark W. Baxter as superintendent of Ingleside Asylum, Hastings. The new superintendent announces the following appointments: first assistant Dr. F. H. Juegle; second assistant, Dr. C. A. Oaks; thir assistant, Dr. M. J. Gilfillan, and fourth assistant, Dr. Merce B. Croll.

Annual Meeting of Casualty Company.—At the annua meeting of the Physicians' Casualty Association of America the proposal to remove the home office from Omaha to Chicag is said not to have been favorably received. Dr. DeWitt C Bryant was reelected president; Dr. Dellizon A. Foote, vice-president, and Drs. LeRoy Crummer, Robert A. Gilmore an Charles C. Allison were reelected directors, all of Omaha.

County Medical Society Meetings.—At the annual meeting of Boyd County Medical Society, held in Lynch, February 10 Dr. George W. Ira, Lynch, was elected president; Dr. George E. Darrow, Butte, secretary-treasurer; and Dr. John R Beatty, Butte, delegate to the state society.——Nuckolls County Medical Association, at its recent meeting in Nelson elected Dr. John W. Mitchell, Superior, president; Dr. Edwin M. McGee, Nelson, vice-president; Dr. Frank Mitchell, secretary.——York County Medical Society has elected the following officers: president, Dr. Orville M. Moore; vice-president, Dr. Frank G. Snyder; secretary-treasurer, Dr. James N. Plumb; delegate to the state society, Dr. Walter F. Reynolds, all of York; and alternate, Dr. George A. Morrison, Bradshaw.——Physicians of Stanton County met January 31, and organized a county medical society and elected Dr. William R. Peters, president; Dr. Emil C. Underberg, secretary, and Dr. William H. Person, treasurer, all of Stanton.

NEW HAMPSHIRE

Bequest.—By the will of the late Dr. George F. Wilbur, Nashua, about $60,000 is devised to the Nashua Emergency Hospital.

Personal.—After a continuous service of twenty-one years, as executive officer of the Dover Board of Health, Mr. Charles M. Jones has retired.——At the annual banquet of the Manchester Medical Association, held February 14, and at which Dr. Wellington A. Thompson presided, the addresses of the evening were given by Dr. Edward W. Taylor, Boston, on "Infantile Paralysis," and by Dr. Harvey P. Towle, Boston.

NEW JERSEY

Wall Paper Regulation.—The Bayonne Board of Health has added to the sanitary code of the city rules prohibiting the placing of new wall paper on the walls of any dwelling until the old paper has been removed and the wall thoroughly cleansed.

Personal.—Dr. Ervin C. Towne, resident physician at Cooper Hospital, Canton, is reported to be seriously ill with septicemia.——Dr. Wells P. Eagleton has succeeded Dr. Charles J. Kipp as medical director of the Newark Charitable Eye and Ear Hospital.——Dr. Edward S. Sharpe, Salem, is reported to be ill at his home.

Societies May Unite.—At a meeting of the Passaic Medical Society, February 9, a motion to unite with the Passaic County Medical Society, was adopted, contingent to the granting of certain conditions, and Drs. George T. Welch, William H. Carroll and Gilbert Van Vranken were appointed a committee to treat with the county society.

Academy of Medicine Organized.—Formal organization of the Academy of Medicine of Northern New Jersey was effected at a meeting held in Newark, February 25. A constitution and by-laws were adopted and the following officers were elected: president, Dr. Edward J. Ill, Newark; vice-presidents, Drs. Thomas N. Gray, East Orange; Wells P. Eagleton, Newark, and secretary, Dr. Julius Levy, Newark. One of the provisions of the constitution is that dentists may become associate fellows of the organization and have a separate section where they can pursue their own branch of study.

Health Lectures.—A series of free public lectures on health is being given at Newark under the auspices of the Public Education Committee of the Essex County Medical Society, the Public Health Committee of the State Federation of Women's Clubs, and the College Women's Club. Lectures have already been given on "Food Fads" by Dr. Richard C. Newton, Montclair; on "The Eye in Health and Disease" by Dr. Linn Emerson, Orange; and on "Clean Streets for Health" by Dr. William Buermann, Newark. On March 22, W. F. Barry, Orange, will speak on "The Care of the Teeth in Relation to Health;" on April 10, Dr. Christopher C. Beling, Newark, will take up "The Cause and Prevention of Nervous and Mental Diseases;" and on May 1, Dr. Thomas N. Gray, East Orange, will discuss "The Social Evil and Its Effects on Public Health."

NEW YORK

Bequest for Nassau Hospital.—The will of Mrs. Alice Hicks of Westbury, L. I., gives $100,000 to the Nassau Hospital, Mineola, L. I.

Hospital Closed.—The New Amsterdam Eye and Ear Hospital in West Thirty-Eighth Street has received permission from the courts to sell its property for $60,000. The reason given for this action is that the institution is not paying.

Wood Alcohol Kills Three.—Three out of five persons who drank wood alcohol believing it to be grain alcohol at a wedding anniversary celebration near Middleton, N. Y., died from the effects of the beverage. The man who sold the stuff has fled and the authorities are searching for him.

Bill to Protect Marriage.—A bill has been brought before the legislature providing that no marriage license shall be issued until each party has presented a doctor's certificate of freedom from any contagious, infectious or transmissible disease, and making it a misdemeanor to procure such a certificate by fraud.

For Better Milk.—The committee of the New York Milk Committee, known as the Committee for the Reduction of Infant Mortality, in its endeavor to raise the sum of $300,000 has sent appeals to a large number of women who were thought able to contribute, and women will follow up this appeal by a street canvass for contributions to this fund.

Harvey Society Lectures.—The seventh of this course of lectures will be delivered on March 25 by Prof. H. Gideon Wells, of the University of Chicago, on Calcification and Ossification. The eighth and last lecture of the course will be delivered on April 1 by Dr. S. Weir Mitchell of Philadelphia, the subject being "William Harvey, the Discoverer of the Circulation of the Blood."

Bellevue Alumni Dine.—After participating in the twenty-fifth annual meeting of the organization 250 Bellevue alumni dined at Delmonico's and listened to addresses by Dr. Charles F. Stokes, Surgeon-General of the Navy; Drs. William K. Polk, Joseph D. Bryant, John W. Brannan and Floyd M. Crandall. Dr. Starling Loving of Columbus, O., who was one of the first paid interns and served in 1849 and 1850 at the time of the cholera epidemic, was present.

New York City

Bronx Hospital for Bronx Physicians.—Declaring that Bronx physicians exclusively are entitled to attend Bronx patients, a number of medical men of the borough protested to the State Board of Charities, February 27, against the opening of a new hospital in that borough by Dr. Abraham Jacobi and seventeen physicians and surgeons, fifteen of whom are said to be residents of Manhattan.

Personal.—Dr. Theodore C. Janeway has been appointed senior attending physician of the Presbyterian Hospital as the result of a recent tentative agreement between the hospital and Columbia University. Dr. William G. MacCallum has been appointed pathologist to the hospital.——Dr. Williams McKim Marriott, assistant to the chair of physiologic chemistry in Cornell Medical School, has been appointed instructor in biologic chemistry in Washington University, St. Louis.

Gifts to Hospitals.—The late Melville W. DeWolf left a bequest of $5,000 to the Presbyterian Hospital to establish the Emma DeWolf bed for children, and $5,000 to Roosevelt Hospital to establish the Carlton DeWolf free bed.——The Society of the Lutheran Hospital of the City of New York, formed for the purpose of building a Lutheran Hospital in this city, has received a donation of eight lots near Central Islip, L. I., on which to erect a home for convalescents. The name of the donor is withheld. The society has been pledged about $250,000 toward the erection of a city hospital, of which $100,000 was given by John Riehle.

OKLAHOMA

County Medical Society Election.—At the recent meeting of the Tillman County Medical Association, held in Frederick, the following officers were elected: president, Dr. Adam B. Fair, Frederick; vice-president, Dr. Francis E. Rosenberger, Grandfield; secretary-treasurer, Dr. John P. VanAllen, Frederick; alternate delegate to the state association, Dr. James D. Osborn, Frederick; censor, Dr. John H. Hanson, Grandfield.

Personal.—Dr. William N. McGee, local surgeon of the Rock Island System at Shawnee, has resigned and has been succeeded by Dr. Charles H. Blickensderfer, Tecumseh.——Dr. W. H. Slaughter, a colored physician of Oklahoma City, was seriously injured recently in a collision between his buggy and a heavy wagon.——Dr. Walter Hardy, Ardmore, has approved plans for a sanitarium to be built by September 1.——Dr. C. A. Steward, Allen, is reported to have been convicted of manslaughter in the second degree, and to have been sentenced to imprisonment for three years in the penitentiary. The charge was that he shot and instantly killed a formerly intimate friend, during a quarrel, on Christmas eve, 1909.

PENNSYLVANIA

Hospital Opened.—After unexpected delays the Meyer Emergency Hospital, Erie, was opened for patients, February 19.

New Bulletins for Health Department.—Bulletins 16 and 17, issued by the State Department of Health are on "The Conservation of Infant Life in Pennsylvania," and on "Pennsylvania's Standing Army of Health."

Personal.—Dr. Charles P. Woodring has been appointed a member of the board of health of Meadville.——Dr. Leroy W. Braden had a narrow escape from drowning while attempting to ford a flooded creek near his home at Ten Mile.

Gifts to Hospitals.—Mrs. Minnie Bachman, Sharon, has given $10,000 to Lancaster General Hospital, to provide a free room in memory of the donor's husband, Morris Bachman.——By the will of the late Abraham Weitzenkorn, $500 is bequeathed to Pottstown Hospital.

Philadelphia

Hospital Addition Dedicated.—Bradley Hall, the new addition to the Methodist Episcopal Hospital, was formally dedicated on February 25. Bishop C. W. Smith made the principal address at the exercises. Mr. Thomas Bradley, president of the board of trustees, is the donor of the building, which cost $40,000, and will be used for kitchens, store-rooms, dining rooms and dormitories.

Personal.—Drs. *Charles K. Mills and William G. Spiller* have been elected *foreign corresponding members of the Société* de Neurologie, Paris.——As Dr. John H. Musser has refused to allow his name to be considered for the professorship of practice of medicine in the University of Pennsylvania, Dr. Alfred Stengel, professor of clinical medicine, has succeeded to the chair.——Dr. S. Weir Mitchell celebrated his eighty-first birthday, February 15.

New Officers.—The president of the Philadelphia County Medical Society, Dr. Christian B. Longenecker, has made the following appointments for the year 1911: Committee on Public Policy and Legislation, Drs. Hobart A. Hare, George A. Knowles, Wilmer Krusen, John D. McLean and L. Webster Fox, chairman; committee on membership, Drs. Mary Buchanan, M. Howard Fussell, George C. Yeager, Milton F. Percival and Samuel Wolfe, chairman; committee on library, Drs. Edward E. Montgomery, Elizabeth L. Peck, Albert M. Eaton, Herman B. Allyn and James M. Anders, chairman; and reporter, Dr. Howard C. Carpenter.——At the meeting of Philadelphia Medical Club, January 20, the following officers were elected: president, Dr. William L. Rodman; vice-presidents, Drs. S. Lewis Ziegler and Gwilym G. Davis; secretary, Dr. J. Gurney Taylor, and treasurer, Dr. Lewis H. Adler, Jr.; governor (for 5 years) Dr. Edward L. Duer.——The new officers chosen by the Kensington Branch of the County Medical Society include: chairman, Dr George H. Nofer, and clerk, Dr Valentine R. Manning.——The Northern Medical Association has elected the following officers: president, Dr O. Luther Latchford; *vice-president*, Dr. *Paul F. Bremer*; secretary, Dr. Lee Boyce; *corresponding secretary*, Dr. Thomas Shriner, and *treasurer*, Dr. *John W. Millick*.——The following officers were elected by the North Branch of the County Medical Society for the year 1911: Dr. Wilmer Krusen, *chairman*; Dr John Leedon, clerk; Dr. Samuel P. *Gerhart* was elected associate vice-president of *the county society* to represent this branch.

VIRGINIA

Sanatorium Opened.—The Birdville Sanatorium for Consumptives, Petersburg, was formally *opened*. February 14

Election.—At the quarterly meeting of the Alexandria Medical Society, *the following* officers were elected: president, Dr. William M. Smith, Alexandria; vice-presidents, Drs. Samuel B. Moore, Alexandria; and T. F. Dodd, Fairfax County; secretary, Dr. Llewellyn Powell, Alexandria, and treasurer Dr. R. J. Yates, Alexandria County.

Undergraduates' Association.—Students of the *third and* fourth year classes of the University College of *Medicine*, Richmond, have organized an undergraduate surgical association according to the plan adopted a few years ago by the University of Pennsylvania. The association meets every Thursday evening and discusses surgical questions. The officers *of the association* are: president, W. M. Burnett; vice-*president*, O. L. Hamilton, and secretary-treasurer, C. J Allen.

Personal.—Dr. Alexander G. Brown, Richmond, has been *commissioned* captain, Medical Corps, Virginia Volunteers.——Dr. Frank H. Hancock, Norfolk, has been appointed quarantine officer of the Elizabeth River District, vice Dr. Powhatan S. *Schenk*.——*Dr*. William E. Jennings, Bedford, has been *appointed* resident physician at the Catawba Sanatorium, vice *Dr*. William D. Tewksbury, resigned to accept the position *of* superintendent of the District of Columbia Tuberculosis Hospital.

GENERAL NEWS

New Member of Referee Board.—Secretary Wilson has *appointed Dr*. Theobald Smith, Harvard Medical School, to fill *the* vacancy in the Referee Board of Consulting Scientific Experts caused by the death of Dr. Christian A. Herter, New York City.

Report on Cholera in Honolulu.—Up to March 5, *nineteen* cases of cholera have developed in Honolulu, with *fifteen deaths*. all the deaths being of native Hawaiians. As a precautionary *measure* the schools in one district of the city have been *closed*.

Orriss Under Arrest.—A. W. Orriss, concerning whom a warning was published in The Journal, February 11, page 432, has been arrested on complaint of Dr. J. C. Atwell, Butler, Pa., and is in jail at that place, charged with obtainin money on false pretenses.

New Officers of Sanitary Association.—*At the meeting of th* Lake Michigan Sanitary Association, noted in the issue o March 4, page 679, Dr. William D. Weis, health commissione of Hammond, Ind., was elected president; Dr. Henry B. Favil Chicago, first vice-president; and Dr. Aaron J. Lauer, Whiting Ind., member of the executive committee.

Tri-State Medical Society Meeting.—The *annual meetin* of the Tri-State Medical Society of Virginia and the Carolina was held in Raleigh, N. C., February 22 and 23, under th presidency of Dr. Joseph A. White, Richmond, Va. The following officers were elected: president, Dr. J. Howell Wa Waynesboro, N. C.; vice-presidents, Drs. Thomas E. Anderso Statesville, N. C.; William E. Anderson, Farmville, Va.; an Frank H. McLeod, Florence, S. C., and councilors, Drs. Edwar C. Register, Charlotte, N. C.; William W. Fennell, Rock Hil S. C., and Samuel Lile, Lynchburg, Va. The next meetin will be held in Columbia, S. C., Feb. 21 and 22, 1912.

Sanitation of the Canal Zone.—The *annual report of th* Department of Sanitation of the Isthmian Canal Commissio for 1910 shows a slight increase in the death rate over th previous year due to external violence, but a decrease as compared with the death rate of previous years. During the yea 558 deaths occurred among the 50,802 employees, equivalent t an annual mortality of 10.98 per 1,000. The death rate *amon* white employees from disease was 2.63 per 1,000. Typhoi fever caused 13 deaths during the year; dysentery, 21; pneumonia, 73; and malaria, 50. *One death from yellow feve* occurred January 24. This case was *imported from* Carthagena, and with this exception no yellow fever, plague or smallpox has occurred during the year.

Life Insurance Directors Meet.—The Medical Section of th American Life Convention held its semi-annual meeting in Ne Orleans, February 23-25. Among the important papers presented were those by Dr. H. A. Baker of the Pittsburg Lif and Trust Company on "Substandard Risks," in which h stated *that* the officers of sailing and steam vessels ar undoubtedly the greatest risks to insurance companies an *next to these* come actors, glass workers, naval officers, railwa trainmen, seamen and fishermen, overweight and underweigh risks. In overweights there is likely to be degenerative change and underweights a great risk of tuberculosis. Dr. Frank L B. Jenney, medical director of the Federal Life Insurance Company, Chicago, read an interesting paper on "Office Method and Reporting of Impairments"; and Dr. Amand N. Ravold St. Louis, *discussed* "Uranalysis and Preservation of Urine." The reasons for a national board of health were *considere* by Dr. Albert Anderson, medical director of the *Jefferso* Standard Life Insurance Company. *The association endorse* the Owens bill, and appointed *a committee, consisting* of Drs Albert Anderson, F. M. Cross, and Victor C. Vaughan, Jr. Detroit, to represent the association in the advocacy of thi measure.

Discovery of Poliomyelitis Organism.—The Department o Health of Pennsylvania announces that in examining blood i acute cases of poliomyelitis in human beings and monkeys, i which the disease was produced experimentally, an organis has been found different in morphologic characteristics fron any hitherto described, which may or may not prove th etiologic factor in the causation of the disease. Blood smear being fixed in methyl alcohol and stained with carbol-thionin *the organism* appears as a faintly-stained blue rod with regula *cell* wall about 10 microns long and .8 microns in width curved *at* an angle of 60 to 75 degrees at one end, and occasionall *at* both ends. At times the curved end is bulbous. Some o the organisms appear to have a very finely granular protoplasm, and they are found free in the *serum as well as in th* body of *the red blood* cell. The organisms do not retain the violet color *when* stained by the Gram method but assume the color of the counter stain which is a very dilute solution o carbol fuchsin. The specimens of blood examined were fron *ten* children who had anterior poliomyelitis during the epidemic of last summer and autumn, and from thirteen cases of *the* disease in its acute stage, which had been produced experimentally in monkeys. Blood smears examined from three *normal* human beings and thirteen normal monkeys were carefully examined with negative results. After inoculation with the virus, these monkeys gave positive results. Blood smears were *stained* with iodin and sulphuric acid in order to test the organisms for cellulose. Smears from the cords and brain-of paralyzed monkeys, and from one human being were examined, but none of the new organisms was found. Filtered virus stained with carbol-thionin by Gram's method showed none of these organisms. Defibrinated blood, from three weeks to two months old, from two paralyzed monkeys showed the forms in increased numbers. Cultures made from blood of a paralyzed monkey in blood bouillon, plain bouillon, and blood-agar, examined after an inoculation of three weeks, showed the presence of the organism in increased numbers. Dorsett's egg medium was inoculated with the same blood at the same time, but the organism was not found in smears from surface of the medium or from the water of condensation. Search was made without success for moving organisms in fresh blood, in old tubes of defibrinated blood from paralyzed monkeys, blood bouillon, plain bouillon, serum bouillon cultures three weeks old, and in the condensation water of three-weeks-old cultures on Dorsett's egg medium, under decalcified illumination. Success in isolating the organisms has not yet been reached.

FOREIGN NEWS

Deaths in the Profession Abroad.—Christian Böhr, the leading physiologist of Denmark, professor of the University of Copenhagen, died February 3, aged 56. He was a pioneer in work on the gases in the blood and the gaseous interchanges in the lungs and had recently worked out an ingenious method for determination of the output of blood for the heart beat. He would soon have completed his twenty-fifth year as teacher at the university, and a *Festschrift* is in press intended for that occasion, but which now will serve as a memorial.——G. Mya, an eminent pediatrist of Italy, professor of medical pathology and later of pediatrics at the University of Florence for thirty years, died February 6, aged 63.——James Edward Pollock, F.R.C.P.; one of the oldest fellows of the Royal College of Physicians, London; a pioneer specialist in and writer on tuberculosis; died at his home in London, December 18, aged 92.

Pellagra in Italy.—An official commission has recently been appointed in Italy to study the application of the newer views of the etiology of pellagra. At the first meeting the fine results accomplished to date by the regulations adopted in the last few years were emphasized. In 1888 Italy had 117 pellagrins for each 1,000,000 inhabitants and 80 in 1903. The antipellagra law was then passed and the number was reduced to 39 per 1,000,000 in 1908. The pellagrins formed 7.9 per cent. of the inmates of the insane asylums in 1903, while in 1908 they were only 3.5 per cent. Alessandrini ascribes the disease to a parasite in drinking water and Tizzoni to a special streptobacillus, and both these men are in the commission, so the matter will be thoroughly studied. If either of them is right, then the benefit realized to date by the measures based on the assumption that spoiled corn is responsible for pellagra, is due merely to the improved hygiene. Antonini stated that research in the United States is confirming the corn theory.

PARIS LETTER

(*From Our Regular Correspondent*)

Paris, Feb. 17, 1911.

The Refilling of Medical Prescriptions

The Société de thérapeutique, some time ago, appointed a commission to investigate and report on the regrettable practice of refilling prescriptions (previously mentioned in The Journal, Feb. 4, 1911, p. 360). The commission found nothing in existing laws which applied to the subject. It offered to the society the following resolutions, which were adopted: 1. When a physician writes a prescription calling for a poisonous drug, the prescription should name, in accordance with the law, the prescribed quantity of the toxic substance, the mode of administration of the medicine, and when necessary, the maximum number of times the prescription may be filled without fresh authorization. 2. Whenever a pharmacist fills a prescription calling for a poisonous substance, he should place his stamp and a new number on it, even if this prescription is already on his register. 3. Prescriptions for solutions for hypodermic use should never be refilled without special authorization of the physician who has prescribed them.

Measures Against the Plague

It is reported from Russia that Professor Zabolotny, who has returned from a tour of investigation in the far East, states emphatically that at present neither Siberia nor European Russia is threatened with the plague. This optimistic assurance, however, fails to quiet public alarm in view of the frightful rapidity with which the plague has spread southward among the people of the yellow races. In spite of the activity of the Russian and the Japanese governments, which are aided by a knowledge of the customs and the language and therefore find the population with which they have to deal more tractable, the situation is a grave one, all the more that the portion of the Manchurian region under Japanese control is only a small part of the immense Chinese empire, and that the Chinese administration has shown itself so unequal to the situation that Chinese physicians themselves have refused their assistance so long as the sanitary administration is not organized along European lines.

In France, the parliamentary commission of hygiene has just decided to ask the minister of the interior to hasten the meeting of an international conference to study the means of checking the epidemics of plague and cholera. Moreover, Dr. Broquet, of the Institut Pasteur, has just left for Manchuria, taking with him a large number of chests containing ampullas of Haffkine's serum, which are intended for our soldiers and countrymen sojourning in the threatened localities of the far East. It is felt that the time has come to organize in defense of the civilized world a new scientific expedition to China for the study of this scourge, like that which studied the bubonic plague in Bombay in 1897.

The Name of Malta Fever

The governor of the Island of Malta recently complained that the name of "Malta fever" was not suitable for a disease which is found all along the Mediterranean coast as well as in other countries not bordering on the Mediterranean. The question was laid before the Académie de médecine, which appointed a commission to study the subject. Professor Widal, who presented the report of the commission, proposed to replace the name of "Malta fever" by that of "Mediterranean fever." Professor Blanchard objected that this term seemed scarcely better justified than Malta fever, since the disease is found in other regions. Geographical names, moreover, have the disadvantage of being restricted and incomplete. Blanchard, therefore, proposed to call the disease "undulating fever" (*fièvre ondulante*). Professor Chauffard preferred the name "melitosis," which has the advantage of recalling the cause of the disease, the *Micrococcus melitensis*. Drs. Landouzy and Vaillard supported Chauffard's proposition, on the ground that, in man, the undulating character of the fever may not be evident in the abortive forms and that, moreover, though the *Micrococcus melitensis* produces an undulating fever in man, its manifestations in animals are quite different.

Agitation Among Students in Dental Surgery

A delegation of students in dental surgery has laid before the Chamber of Deputies a petition protesting against the reservation of certain posts, such as that of surgeon-dentist of the hospitals, for doctors in medicine alone. The students believe that, since five years of study, attested by a series of difficult examinations, are demanded of surgeon-dentists, the latter should have the right to compete for the post of surgeon-dentist on the same terms as doctors in medicine.

BERLIN LETTER

(*From Our Regular Correspondent*)

Berlin, Feb. 16, 1911.

Pay Wards in Municipal Hospitals

The question of the establishment of wards for pay patients in the municipal hospitals, of which I have written several times, has lately made some progress. The administration has agreed to the suggestions of the commission which has been considering this matter. All that is needed now is the consent of the city council. According to the resolution, a special building with fifty to sixty beds is to be erected in connection with the surgical clinic at the Moabit Hospital as an experiment, the beds to be available for paying patients of the so-called middle class. These patients, as a rule, are to be placed in small wards of from three to five beds. A number of single rooms is to be provided for patients who need temporary isolation. This section of the hospital is for the benefit of those members of the middle class who are not in position to pay higher fees without too much of a drain on their means. The daily fee for care including the physicians' services amounts to $1.60 (6.50 marks). For the more important operations a special fee as high as $25 (100 marks) may be charged. Also other special services are to be compensated at moderate fees. If patients are received whose circumstances warrant it, higher fees may be charged and in such cases the physician may make special charges. The decision as to whether the circumstances warrant higher or lower charges is reserved to the city authorities.

Regulation of Automobile Traffic

At the request of the Royal Automobile Club of Bavaria the Munich Ophthalmologic Society has made the following report in regard to the requirements for the visual capacity of automobile drivers: 1. The lowest capacity of the eye with the better vision must be 2/3, and of the eye with the poorer vision 1/3 of the normal. The highest permissible correction is + 8.0 diopters. Spectacles and reserve spectacles with an arrangement to protect the glasses from rain and snow must be provided. 2. A retraction of the field of vision which is distinctly demonstrable with the perimeter even in one eye, is a disqualification. 3. A reduction of the sensitiveness to light also disqualifies. 4. Congenital color blindness is not to be considered. 5. Ptosis, paralysis of the eye muscle, considerable disturbance of the mobility of the pupil, aphakia and especially external inflammations, which are accompanied by photophobia, for instance, render the applicant unfit. 6. Goggles are recommended. 7. There should be reexamination every two years.

Statistics of Curative Treatment of Tuberculosis

From the latest statistics of the Imperial Insurance Office on the curative treatment of tuberculosis in the institutions for invalid insurance, a number of important results can be deduced especially because they extend over the period from 1897-1909. During this time, 275,000 patients with pulmonary tuberculosis have received prolonged expert treatment, costing in all over $25,000,000 (100,000,000 marks) Since 1897, the number of men treated for tuberculosis of the lungs has increased more than eleven times and that of women nearly eighteen times. The cost of treatment has continually increased in correspondence with the increased cost of living. The average expense for a tuberculosis patient in 1897 was $76 (307 marks), in 1909, $96 (386 marks) The expense for a day's treatment has risen from $1 (4.05 marks) in 1897 to $1.35 (5.41 marks) in 1909. The treatment of patients with pulmonary tuberculosis was carried out in the so-called people's sanatoria. There are thirty-seven establishments for treatment of diseases of the lungs and thirty-four sanatoria, convalescent homes and hospitals, which are essentially sustained by the invalid insurance societies. On account of the well-known difficulty of keeping a patient who has a family to support in the sanatorium for a sufficient length of time, the law provides for aid to those dependent on the patient, allowing half of the amount paid for sickness by the Krankenkassen or one-fourth of the day's wages; in some cases this is doubled or even tripled. Unmarried insured patients in many cases are assured especial allowance for illness according to the rates of the Krankenkassen, up to one-fourth of the day's wages. In this way, between 1897 and 1909 the sum of $4,250,000 (17,000,000 marks) was paid to relatives and for the special sick benefit; in 1909, $37,000 (148,000 marks) was paid. The results obtained each year at the close of the treatment have been followed for five years so that the latest statistics give the conclusions for nine such periods of five years. In the last eight control periods the initial successes compared with the first period have risen in tuberculous men from 4 to 13 per cent. and in tuberculous women from 5 to 15 per cent. The end-results, on the other hand, have risen from 3 to 19 per cent. in tuberculous men and from 3 to 20 per cent. in tuberculous women. The women treated in all the control periods show a markedly greater permanence of the cure than the men, a result which must be referred to the more marked vitality of women. While at the end of 1901 of 100 men treated for tuberculosis in 1897 only twenty-five had preserved the favorable initial result, the number of those treated in 1905 who showed a continuance of the cure in 1909 was forty-four. On the other hand, for every 100 tuberculous women treated in 1897 at the end of 1901 there were thirty-two able to work and of those treated in 1905 at the end of the year 1909 fifty-two were still able to work. These numbers show also that from year to year better results have been achieved in the treatment of tuberculosis. Of the patients treated in 1909, 1,215 men and 5,826 women were found at the beginning of the curative treatment in the first stage according to the Turban-Gerhardt classification: 9,161 men and 3,399 women in the second stage; 3,550 men and 1,154 women in the third stage. Of all three stages there were at the close of the treatment 535 men and 358 women in stage O. The first stage showed in comparison with the beginning an increase of 1,489 men and 521 women, while the second stage showed a decrease of 1,475 men and 757 women; the third stage a decrease of 553 men and 122 women. In order to reach as completely as possible those persons whose health is endangered the military examinations have been put at the service of the campaign against tuberculosis. It has been arranged that the data regarding the health of those examined for military service by the military surgeons should be communicated to the tuberculosis authorities. In 1909 the organization learned of 575 tuberculous patients in this way.

Improvement of Instruction in Pediatrics

The pediatric society has called attention in memorials addressed to the governments of the various federal states to the insufficient opportunities for instruction in diseases of children in most of the German universities and has made the following demand: It is imperatively necessary that every university possess a children's clinic with a modern infant ward (of at least sixteen beds and some nurses), and a policlinic for children, separate from that for adults. These institutions should be under the direction of a special professor who is to have a voice in the faculty in matters pertaining to the pediatric department. Two hours a week for only one semester are not considered sufficient for attendance on these pediatric clinics. The importance of diseases of children in practice makes an examination in this department necessary for the state license, and this examination should be held by a special professor and rank in importance with the examination in internal medicine. How far these demands will be accepted by the government remains to be seen. Many university professors and many physicians take the position that pediatrics should not be regarded as a specialty, but that it falls properly in the field of instruction in internal medicine and in practice belongs to the sphere of the family physician. This conception is justly opposed. The field of investigation in pediatrics has widened so much in late years that its facts cannot be sufficiently considered in the instruction in internal medicine, and the difficulties in diagnosis and therapeutics in the practice of diseases of children require occasionally the counsel of a specially educated pediatrician, although it must be admitted that every practitioner should understand so much of pediatrics that he will have a sufficient experience for ordinary cases.

VIENNA LETTER

(From Our Regular Correspondent)

Vienna, Feb. 23, 1911.

Sudden Death of Professor Escherich

The news of the death of Professor Escherich, the well-known professor of pediatrics, will without doubt be received with great regret by the numerous American doctors who have been working under him in this city. His clinic was a Mecca for all these men, for it hardly had its like in Europe as regards the advantages for study. Besides, Escherich himself was a very good teacher, who understood how to captivate the thoughts of his students and to direct them to certain roads of reasoning. Out of the great number of his pupils von Pirquet's name is familiar to all practitioners. Escherich's efforts were directed to the prevention of infantile mortality by recommending breast-feeding in all cases, and by the institution of milk distribution for those who were unable to obtain it in a sufficiently pure state. His school is famous for the chemical and biologic researches undertaken under his supervision; the discovery of the *Bacillus coli* is due to one of his earliest undertakings in this line, and has made his name a household word in scientific medicine. He was the representative pediatrist invited to present this specialty at the Congress of Arts and Sciences at the St. Louis Exposition in 1904. He was only 54 years of age when his brilliant career was closed by an attack of apoplexy, brought on by an early arteriosclerosis.

Celebration of Washington's Birthday

This national festival was celebrated in Vienna by a reception in the halls of the embassy of the United States, where Mr. Richard C. Kerens, the ambassador to the Austrian court, gave a formal evening to the members of the American colony at present living in our city. A large number of those present were doctors, members of the American Medical Association of Vienna, which at present is flourishing as never before. The ambassador is a frequent guest in the headquarters of the Association, and thus excellent relations are kept between the two "powers."

BUDAPEST LETTER

(From Our Occasional Correspondent.)

Budapest, Feb. 7, 1911.

State Protection of Children in Hungary

Hungary is justly proud of her system of caring for dependent children, of whom there are now 50,000 in the special institutions provided for them by the Hungarian government. In addition to this large number at present under its protection, the state has previously had 50,000 other wards who either have since been given back to their parents, or, having reached their fifteenth year, have been dismissed from the charge of the state. The system in vogue is generally regarded as one of the foremost humanitarian institutions of the civilized world, and has been lauded as such at recent international congresses of hygiene and child welfare, while experts come to Hungary from all parts of the civilized world to study the details of the methods.

DETAILS OF THE SYSTEM

The homes for children consist of seventeen large buildings in different parts of the country. Every child who has no supporter, or whose maintenance and education are not sufficiently ensured, either on account of poverty or bad hygienic conditions or other adverse circumstances, has a legal right to be cared for by the state. He is not obliged to sue for admission, but he can present himself and claim admission on the ground of legal right. Nowhere else in the world does a child possess such a privilege. In Germany, for instance, the child has no such right, as regards the state, and deserted children are referred to the village charity. In France such cases have to be brought to the notice of the county council.

ABSENCE OF RED TAPE

Another prominent feature of the Hungarian system is that no documents are necessary for proving the fact of a child's abandonment. The Hungarian homes, therefore, take in any child who appears not to be under proper guardianship, and only after the state has received him into its care will inquiries be made through the Society for Protection of Orphans as to whether he is really dependent on the state's care or not. Illness among the children in these homes is treated by medical experts, who have at their command a large number of wet-nurses, assistants, incubators and all necessary surgical appliances, constituting a well-equipped modern hospital.

HEALTHY CHILDREN BOARDED OUT

Healthy children are not brought up in the institutions as "hot-house specimens of humanity," not knowing the trials and troubles of life. Such children are placed by the state in suitable households of the artisan or agricultural class, where they grow up as members of the family and ultimately become useful Hungarian citizens, irrespective of their former nationality. Even though such families are carefully chosen, the state still reserves the right of control. For this purpose, the services of the county physician are requisitioned, extra payment being made for this work. He is required to assure himself as regards the health of the children, their bodily and mental development, and their condition with respect to cleanliness and clothing. In the case of infants, he must supervise the feeding of the child and take its weight from time to time. The state will shortly appoint a lady supervisor, in addition to the already existing district medical officers. Her duties will be the carrying out of the details prescribed by the medical officer and repeated visits to the foster-families, wherein she will take the part, not so much of a government official, as of an aunt to the adopted child and a relative of the family. In the event of the foster-parents proving unsuitable, she will have the child removed to more appropriate surroundings.

TIES OF RELATIONSHIP FOSTERED

The intercourse between the child and its blood relations does not cease when it becomes the ward of the state. This is not the case in other countries; in Paris, for instance, as soon as a child is taken in [illegible] nother is not allowed to apply for [illegible] ore than four times a year. In [illegible] a very different system prevails. It often happens that, in the case of infants, the mother and child are not only separated, but, if the mother requires it, suitable accommodation is provided for her by the state. In the case of children the mother is requested to visit the child, and, as far as possible, to help in its up-bringing. Should she in any case be of the opinion that her child's surroundings are unsuitable to its proper physical or mental development, she can, by reporting this to the state authorities, have the child removed elsewhere, even though her complaints should be due merely to a mother's natural anxiety. Should the mother's or the relations' or even the child's circumstances change, so that the child could be brought up at home, the mother may at once reclaim the child without being put to the expense of any reimbursement of its past maintenance.

SUPERVISION OF STATE CARE BY CITIZENS' ASSOCIATION

The relations between the child and state are controlled by an independent body called the Orphans' Protection Society, which is chosen from among the citizens of the community and is invested with magisterial authority. The result is expected to be a decrease in infant mortality, and also in the number of juvenile criminals, because it has been found that the majority of such criminals were those who had been abandoned to chance in their early years.

MORAL WELFARE OF CHILDREN GUARDED

The Hungarian government also takes measures to prevent the corruption of children's morals. By an order of the minister of the interior, children are taken charge of by the state if it is found that they are being brought up in immoral surroundings. Children in such a case, even though the parent may be in a position to provide for all physical wants, are removed from these evil influences.

EXPENSE TO THE STATE

By protecting children in these various ways, the state is accomplishing a great work which cannot fail to have a beneficial effect on the whole Hungarian people. The yearly expenditure by the state for the protection of children amounts to $2,000,000.

The Outlook for Medical Men in Hungary

The number of medical men in Hungary is increasing constantly, but the prospects of the practitioners are not increasing at the same rate. This is chiefly important for a large percentage of the present doctors in Hungary, for as an investigation conducted by a medical corporation in this country shows, fully 32 per cent. of all medical students and recently graduated doctors come from the poorest and often lowest strata of the population. Therefore medical organization could not be successful in this country, for the newly qualified M.D. is always willing to do anything to earn even a small living as quickly as possible. The Hungarian ministry for education has just now ordered that the holders of diplomas gained abroad (Austria included) can apply for the right to practice only under the condition that they produce proofs of having passed examinations absolutely equivalent to those required from a medical student in Hungary (knowledge of Latin, Greek, an equal curriculum, and the same subjects as are required in Hungary).

Marriages

Joseph B. Cox, M.D., to Miss Dollie Clements, both of Howell, Ind., March 1.

Ebb. C. Johnston, M.D., to Miss Madge Good, both of Chattanooga, Tenn., February 23.

Eugene D. Regan, M.D., to Miss Marion Smith, both of Milwaukee, Wis., February 22.

A. F. McKay, M.D., to Mrs. Laura V. Smith, both of Colorado Springs, Colo., February 22.

Eugene E. Coerper, M.D., Fredonia, Wis., to Miss Madeline A. Oppen of Milwaukee, February 22.

Pauline I. Myers Townsend, M.D., and Lawrence A. Hanson, both of Marshalltown, Ia., recently.

Harry William Ackermann, M.D., Rockford, Ill., to Miss Maud Goodspeed of Elgin, Ill., February 21.

Isaiah J. Waterman, M.D., Creston, Ia., to Miss Rachel Kegley of Colfax, Ia., at Des Moines, February 20.

Claude W. Asbury, M.D., Hymera, Ind., to Miss Abby Lucas of Sullivan, Ind., at Terre Haute, Ind., February 21.

Frank M. Humphrey, M.D., Bluemont, Va., to Miss Lillian Rosa Belle Talbott, at Washington, D. C., February 22.

Frank John Hirschboeck, M.D., Chisholm, Minn., to Miss Elizabeth Robertson Carmichael of Lansing, Mich., February 16.

Deaths

Walter Remsen Brinckerhoff, research worker and pathologist, who spent five years as director of the Molokai (H. I.) Leprosy Investigation Station of the U. S. P. H and M.-H. Service; died at his home in Jamaica Plain, Boston, Mass., March 2, from pneumonia, aged 36. Dr. Brinckerhoff graduated from Harvard University in 1897, and from Harvard Medical School four years later. His expert training in pathology was obtained in the laboratory of the Boston City Hospital, where he was successively intern and second and first assistant in pathology. In 1902 he was made assistant in pathology in his alma mater. Two years later he was made a fellow of the Rockefeller Institute for Medical Research, and in 1905 was appointed physician to the Carnegie archeologic expedition to the Transcaspian Territories. He made researches on the white cells of the blood and small-pox, carrying on the latter work in Boston in 1901 and 1902, and in Manila in 1903 and 1904. In 1906 he was placed in charge of the Leprosy Investigation Station at Molokai, and remained there for nearly five years, returning a few months ago to accept the assistant professorship of pathology in Harvard University. He was a member of the Massachusetts Medical Society, the American Association of Pathologists and Bacteriologists and the Society of Experimental Medicine. Dr. Brinckerhoff was highly esteemed by his associates, and his untimely death deprives the scientific world of a notable research worker.

William Worrall Mayo, M.D., pioneer surgeon of Minnesota, died at his home in Rochester, March 6, aged 91. He was born near Manchester, England, received his preliminary education at Manchester College, and took his medical lectures at the Indiana State Medical College in 1852, and at the University of Missouri Medical Department, Columbia, from which he received the ad eundem degree of M.D. in 1854. He first settled in Lafayette, Ind., but soon moved to Rochester, Minn. He was for many years a member of the American Medical Association and was president of the Minnesota State Medical Association in 1872. Soon after his arrival in Minnesota he was made surgeon-in-chief of the provost-marshall's office for the southern district of Minnesota. Dr. Mayo was the pioneer surgeon of the northwest and established a reputation which has resulted in making Rochester the surgical Mecca of the United States.

Albert Sydney Ashmead, M.D., of New York City; research worker in leprosy, pellagra and Asiatic diseases; died in Jefferson Hospital, Philadelphia, February 20, after an operation for disease of the intestines, aged 60. He received his medical degree from the University of Pennsylvania, Philadelphia, in 1869, and four years later was appointed foreign medical director of the Tokyo Fu Hospital, Tokyo, Japan. He also taught the first class of students in the Tokyo Charity Hospital Medical School. After three years he returned and practiced in Doniphan County, Kan.; and while there was local surgeon for the St. Joseph and Grand Island Railroad. In 1882 he removed to New York City. He was one of the founders of the Berlin Leper Conference of 1897, and contributed largely to the literature of leprosy.

Thomas Berton Davis, M.D. University of Louisville, Ky., 1869; a member and formerly president of the Arizona Medical Association; organizer and first president of the Yavapai County Medical Society; a pioneer physician of Arizona; formerly medical cadet and acting assistant surgeon, U. S. Army, with Civil War service; died at his home in Prescott, February 17, from intestinal obstruction, aged 66. At a special meeting of the Yavapai County Medical Society, resolutions were unanimously adopted setting forth the high personal and professional attainments of Dr. Davis, and expressing regrets at his death. These resolutions were endorsed by the druggists of the city.

Edwin H. Carter, M.D. Eclectic Medical Institute, Cincinnati, 1865; Rush Medical College, 1897; for several years a member of the Iowa State Board of Health; and State Board of Medical Examiners; vice-president of the Iowa Public Health Association; formerly professor of surgery and clinical surgery, theory and practice of medicine and clinical medicine, and dean of the faculty of Drake University Medical Department; died at his home in DesMoines, February 24, from cerebral hemorrhage, aged 74.

James Crawley Donoghue, M.D. *cum laude*, Harvard Medical School, 1897; of Boston; a member of the American Medical Association; instructor in histology in his alma mater; and last year appointed instructor in diseases of the blood in Tufts College Medical School; physician for twelve years at the Boston Dispensary and visiting physician to St. Mary's Infant Asylum; died at the home of his parents in Georgetown, Mass., February 26, aged 46.

Franklin Cooley, M.D. University of Louisville, Ky., 1848; surgeon of the Tenth Missouri Volunteer Infantry and Seventh Missouri Volunteer Cavalry during the Civil War; for sixteen years a member of the local pension examining board of Lexington, Mo.; founder of the first medical college in Kansas City, and professor of surgery for three years; died at the home of his daughter in Kansas City, February 16, aged 90.

Edward Hitchcock, M.D. Harvard Medical School, 1853; senior professor and professor of hygiene and physical education in Amherst (Mass.) College and of physical culture and hygiene in Cornell University; a pioneer in the physical training of students, and the author of a number of text-books on physiology and anatomy; died at his home in Amherst, February 15, aged 82.

Floyd Preston Sheldon, M.D. University of Michigan, Ann Arbor, 1878; an eye and ear specialist of New York City; and a director and vice-president of the Citizens Loan and Saving Association; oculist and aurist to the Home for the Friendless, and consulting oculist to the Webb Home; died at his home in New York City, February 18, from nephritis, aged 53.

Thomas James Manahan, M.D. Harvard Medical School, 1899; assistant surgeon on the hospital ship *Bay State* during the Spanish-American War; a member of the staff of the Massachusetts General Hospital, and proprietor of the McDonald Hospital, Corey Hill, Brookline; died in that institution, February 14, from pneumonia, aged 37.

Francis M. Greene, M.D. Jefferson Medical College, 1860; a member of the Kentucky State Medical Association; for more than half a century a practitioner of Fayette County, Ky.; acting assistant surgeon U. S. Army during the Spanish-American War; died at his home in Lexington, February 19, from senile debility, aged 77.

Homer Baxter Sprague, M.D. Bellevue Hospital Medical College, 1881; a member of the Medical Society of the State of New York; for twenty-six years a practitioner of Yorkville, New York City, and a prominent social worker; a member of the State Lunacy Commission; died at his home, February 25, from pneumonia, aged 51.

Carroll Thrasher, M.D. Cooper Medical College, San Francisco, 1900; at one time police surgeon of San Francisco, and superintendent of the small-pox hospital; and later surgeon on a steamer plying between San Francisco and Panama; died suddenly at his home in San Francisco, February 10, from heart disease, aged 34.

Llewellyn Thomas Botsford, M.D. New York Homeopathic Medical College, New York City, 1878; for several years health officer of Colton, N. Y., and for six years coroner of St. Lawrence County; a member of the board of education of Canton for many years; died at his home in Potsdam, February 8, from diabetes, aged 58.

Stephen Tabor Birdsall, M.D. Homeopathic Medical College of Pennsylvania, Philadelphia, 1868; New York Homeopathic Medical College and Hospital, New York City, 1868; a member of the American Electrotherapeutic Association; died at his home in Glens Falls, N. Y., January 27, from cerebral hemorrhage, aged 65.

James Kelley Farnum, M.D. University of Michigan, Ann Arbor, 1870; surgeon for the Pere Marquette and Grand Trunk systems for several years; died in the City Hospital, Port Huron, Mich., February 11, from shock following the amputation of a foot as the result of a street-car accident four days before, aged 64.

Benjamin Franklin Cessna, M.D. University of Michigan, Ann Arbor, 1852; Jefferson Medical College, 1858; for many years a trustee of Ohio Wesleyan University, in which he endowed a chair of English language and literature; died at his home in Kenton, Ohio, January 1, from acute gastritis, aged 84.

John C. Nottingham, M.D. Bennett Medical College, Chicago, 1873; a veteran of the Civil War; at one time treasurer of Delaware County, Ind.; a charter member and one of the organizers of the Saginaw Valley Medical Society; died at his office in Bay City, Mich., February 25, from heart disease, aged 69.

Alexander S. Stewart, M.D. Eclectic Medical Institute, Cincinnati, 1865; a pioneer practitioner of South Dakota; a veteran of the Civil War; and a member of the legislature from Pawnee County, Neb., in 1869; died at his home in Hot Springs, S. Dak., January 22, from nephritis, aged 71.

Hannibal Amilcar Beeson, M.D. Miami Medical College, Cincinnati, 1879; for many years a practitioner of Leesburg, Ohio; hospital steward and assistant surgeon in the Navy during the Civil War; died at the home of his son in Roswell, N. M., February 11, from angina pectoris, aged 69.

Thomas K. Reed, M.D. University of Pennsylvania, Philadelphia, 1864; vice-president and one of the organizers of the First National Bank of Atlantic City, N. J.; a surgeon of volunteers during the Civil War; died at his home in Atlantic City, February 12, from heart disease, aged 72.

Charles Spinning Cowan, M.D. Miami Medical College, Cincinnati, 1880; formerly president of the Shelby County (O.) Medical Association, and Siskiyou County (Cal.) Medical Society; died at his home in Fort Jones, Cal., Nov. 26, 1910, from angina pectoris, aged 60.

John A. Rynard, M.D. Jefferson Medical College, 1872; formerly councilman and a member of the school board of South Harrisburg, Pa.; local surgeon for the *Pennsylvania System* at Goldsboro from 1880 to 1888; died at his home in Harrisburg, February 10, aged 71.

Alonzo R. Stephens, M.D. Albany (N. Y.) Medical College, 1865; a member of the Bradford County Pension Board; assistant surgeon in the Federal service during the Civil War; died at his home in Herrickville, Pa., February 10, from heart disease, aged 75.

Philo Kelly Stoddard, M.D. Buffalo (N. Y.) Medical College, 1848; surgeon of the One Hundred and Sixty-First New York Volunteer Infantry for two years during the Civil War; died at his home in Prattsburg, N. Y., February 3, from gastritis, aged 85.

Caleb Horace Closson, M.D. Jefferson Medical College, 1872; a member of the Medical Society of the State of Pennsylvania; first secretary of the Altoona Board of Health; died at his home in that city, February 24, from cerebral hemorrhage, aged 62.

E. B. Harrell, M.D. Tennessee Medical College, Knoxville, 1907; a member of the American Medical Association, and of the pension board of Unicoi County, Tenn.; died at his home in Unicoi, Nov. 23, 1910, from typhoid fever, aged 35.

William J. Middleton, M.D. Kentucky School of Medicine, Louisville, 1891; a pioneer practitioner of Idaho; for many years a member of the Idaho State Medical Association; died at his home in St. Anthony, January 13, from paresis.

Wallace Deane Carr, M.D. University College of Medicine, Richmond, Va., 1908; a member of the Medical Society of Virginia; a specialist in diseases of children; died at his home in Richmond, February 24, from heart disease, aged 35.

Amy Garrison Brown Kimball, M.D. Cleveland College of Physicians and Surgeons, 1878; for three years intern in the Northeastern Hospital for Women, Boston; died at her home in Jackson, Mich., January 29, from pneumonia, aged 63.

Emmet Densmore, M.D. New York University, New York City, 1885; of New York City; an apostle of natural food and simplicity in living and diet; died at his cottage in Cassadega, Fla., February 19, from tuberculosis, aged 73.

John J. Sweeney, M.D. College of Physicians and Surgeons, Baltimore, 1910; of Govanstown, Baltimore; died in Mercy Hospital, February 18, from the effects of bichlorid of mercury, self-administered in mistake for candy, aged 25.

Nellie Knowles Horn, M.D. Fort Worth (Tex.) University, 1908; a member of the Tarrant County Medical Society; died at her home in Altus, Okla., January 16, eight days after an operation for cancer of the uterus, aged 36.

Jesse W. Buell, M.D. New York Homeopathic Medical College, New York City, 1877; attending physician to the Rochester (N. Y.) Homeopathic Hospital; died at his home in that city, February 17, from pneumonia, aged 59.

Thomas E. Briggs, M.D. Saginaw Valley Medical College, Saginaw, Mich., 1903; of Saginaw; a member of the Michigan State Medical Society; died at the Saginaw General Hospital, February 23, from pneumonia, aged 32.

Arthur B. Ralph, M.D. Washington University, St. Louis, 1859; of Orrick; a member of the Missouri State Medical Association; died at the home of his daughter in Orrick, February 17, from pneumonia, aged 74.

Gustavus Adolphus Tucker, M.D. Jefferson Medical College, 1854; for thirty-one years an employee of the *Chattanooga Times*; died at the home of his daughter in Hill City, Chattanooga, Tenn., February 10, aged 82.

Joseph W. Bourne, M.D. State University of Iowa, College of Homeopathic Medicine, Iowa City, 1889; formerly of South Auburn, Neb.; died at his home in Omaha, February 14, from arteriosclerosis, aged 53.

George W. Seymour, M.D. New York Homeopathic Medical College, New York City, 1872; for more than forty years a practitioner of Westfield, N. Y.; died at his home, February 13, from pneumonia, aged 69.

David Dunn Martin, M.D. Starling Medical College, Columbus, O., 1851; (license, Okla., 1908); a practitioner for nearly sixty years, died at his home in Newkirk, Okla., February 5, from cancer, aged 82.

James M. Patterson, M.D. University of Nashville, Tenn., 1859; a Confederate veteran; formerly a member of the Tennessee legislature; died at his home in Verona, Tenn., February 18, aged 82.

Rufus C. Corey, M.D. Homeopathic Medical College of Missouri, St. Louis, 1887; of Seattle, Wash.; died in the City Hospital, February 13, from the effects of an overdose of morphin, aged 46.

William G. Mangold, M.D. College of Physicians and Surgeons, New York City, 1889; of Brooklyn, N. Y.; died in the Brooklyn Hospital, February 15, from cerebral hemorrhage, aged 47.

Edward Clay Reid, M.D. Louisville (Ky.) Medical College, 1875; president of the school board of Tulsa, Okla.; died at his home in that place, Nov. 20, 1910, from acute nephritis, aged 58.

Napoleon B. McKay (license, Kansas, 1901); of America City; for fifty-four years a practitioner of Kansas; died at the home of his daughter near America City, February 4, aged 84.

James Kennedy Johnstone, M.D. Victoria College, Coburg, Ont., 1870; government inspector of electric meters; died at his home in Toronto, Aug. 12, 1910, from pneumonia, aged 61.

Lee Washington Fulton, M.D. Rush Medical College, 1869; of New Berlin, Ill.; a practitioner for fifty-four years; died at the home of his son in Alexander, Ill., February 18, aged 73.

Sands Macamly Davis, M.D. New York University, New York City, 1853; died at his home in Sugar Loaf Valley, Mass., January 8, from organic heart disease, aged 81.

Henry J. Weyl, M.D. Eclectic Medical Institute, Cincinnati, 1875; a veteran of the Civil War; died at his home in Decatur, Ill., February 23, from prostatic hemorrhage, aged 75.

Albert Seessel, M.D. University of Leipsic, Germany, 1876; of New York City; died in the German Hospital, New York City, Dec. 24, 1910, from lobar pneumonia, aged 60.

Henry Lewis Perney (license, Iowa, years of practice, 1886); for nearly half a century a practitioner; died at his home in Wilton, February 13, from cancer, aged 74.

Charles Westley Throckmorton, M.D. Western Pennsylvania Medical College, Pittsburg, 1909; died at his home in Johnstown, Pa., February 16, from pneumonia, aged 23.

Joseph E. Ferte, M.D. Ecole de Médecine et de Chirurgie, Montreal, 1853; died at his home in Livingston, Mont., February 12, from cerebral hemorrhage, aged 78.

John F. Michael, M.D. College of Physicians and Surgeons, Baltimore, 1885; died at his home in Morgantown, W. Va., Sept. 26, 1910, from prostatitis, aged 70.

Frank B. Behner, M.D. Kentucky School of Medicine, Louisville, 1902; of Marion, Ohio; died in Richmond Township, February 19, from tuberculosis, aged 30.

George Thomas Borden, M.D. Hahnemann Medical College, Philadelphia, 1876; died at his home in Caledonia, N. Y., February 14, from nephritis, aged 57.

N. W. Williams, M.D. Tulane University, New Orleans, 1875; formerly of Holly Springs, Miss.; died at his home in Gulfport, Miss., February 21, aged 53.

Mathew Wilkinson Ross, M.D. Jefferson Medical College, 1889; died at his home in Scranton, Pa., Sept. 3, 1910, from sarcoma of the lower jaw, aged 56.

Constantine H. Murphy, M.D. Washington University, St. Louis, 1854; died at his home in Chesterfield, Ill., February 13, from heart disease, aged 83.

Jeremiah B. Dustin, M.D. Medical College of Ohio, Cincinnati, 1874; died at his home in Bidwell, O., February 17, from cerebral hemorrhage, aged 62.

William M. Glass, M.D. Medical College of Indiana, Indianapolis, 1871; died at his home in Summitville, Ind., January 27, from nephritis, aged 80.

[**Dr. Daniel Franklin Royer** is not dead; see California news, this issue.]

Association News

THE LOS ANGELES SESSION

List of Meeting Places and Section Hotels—The Northern Railroad Routes

We give here a schedule of meeting places for the various sections and other gatherings and of the hotels designated for the various sections. A map of Los Angeles will be published in the special number of The Journal to be issued in May giving full details of the session. Some information about the meeting is being published in each issue of The Journal. For example, a list of hotels, with description and rates, appeared February 18, page 527.

THE NORTHERN RAILROAD ROUTES

Dr. M. L. Harris, Chicago, chairman of the Committee on Transportation, makes the following announcement, continuing the subject of railroads from the issues of the past few weeks:

The northern routes include the Northern Pacific, the Chicago, Milwaukee & Puget Sound, the Great Northern and the Canadian Pacific railroads, and, for a part of the distance, the Oregon Short Line. All of these routes lead to the northwest, namely, to Vancouver, Seattle, Tacoma and Portland.

On the Canadian Pacific the mountain scenery is perhaps the most beautiful on this continent, and this part of the great Rocky Range frequently has been called the Alps of America. On the other lines, although the mountain scenery is very beautiful, the greatest attraction is undoubtedly the Yellowstone Park. All those who have not visited this great National Park should not fail to improve this opportunity to see the wonderful geysers, the lake, the beautiful Yellowstone falls, the deep canyon with its gorgeous colorings, and many other interesting formations.

There are many beautiful and interesting sights along the Columbia River, including the great salmon fisheries, which are the largest in the world.

The Shasta route between Portland and San Francisco is justly famous, for the stateliness and grandeur of Mount Shasta is unsurpassed.

For those who enjoy the water there is an excellent line of boats between San Francisco and Portland.

The rate over any of these northern lines is $62.50 round trip from Chicago, plus $15 arbitrary for the coast line, but attention is again directed to the fact that this rate is not available for both going and returning by a northern route.

As it requires so much time thoroughly to see and enjoy the Canadian Rockies, Yellowstone Park and the other places of interest, it is suggested that it is perhaps better to go by one of the southern or central routes and to return by a northroute; stop-overs on the return trip may be had at almost any place and for any length of time within the final limit of the ticket, September 15.

SPECIAL TRAINS

Announcement of special trains will be made in The Journal in the issue of March 25. All who are concerned in the arranging of special trains to Los Angeles from any part of the United States, or from Los Angeles on the return trip, are asked to notify The Journal at once with full particulars so that this announcement may be complete.

Federation of Women's Clubs Starts Educational Campaign in Social Hygiene

To the Editor:—It may be of interest to your readers to know that the General Federation of Women's Clubs, with a membership of 800,000, has decided to take up an educational campaign on social hygiene. A committee of three physicians and one lay woman was appointed by the president to start the work. The opportunity is a great one, but the task of doing it wisely and yet of facing the facts honestly is no small one. A large number of women in the federation are not even acquainted with the name "social hygiene;" a still larger number are afraid of the subject.

Our experience in Illinois has been of the most encouraging nature. In the last four years a committee, consisting of a number of women physicians and some lay members of the Chicago Woman's Club, in cooperation with the Chicago Woman's Club and the Chicago Society for Social Hygiene, carried on extensive educational work.

Before almost every club in the city and in the state one or more lectures on social hygiene have been given. Members of the committee have also spoken before mothers' meetings and fraternal organizations. Several public courses of lectures, including the anatomy and physiology of the organs of generation, embryology, sexual awakening, dangers of syphilis and gonorrhea, have been given at the Chicago Woman's Club, at the Chicago Public Library, and at the Chicago Academy of Science. The audiences in many cases were large and apparently took the profoundest interest in the subject.

(*Continued on page 761*)

LIST OF SECTION MEETING PLACES AND HOTELS

Section, etc.	Name of Hall	Location of Hall	Hotel Headq'ters	Location of Hotel
General Hotel Headquarters			Alexandria	5th and Spring
Registration	Hamburger (4th floor)	8th and Broadway		
House of Delegates	Armory	7th and Spring		
Commercial Exhibit	Hamburger (4th floor)	8th and Broadway		
President's Reception	Shrine Auditorium	655 W. Jefferson		
Smoker	Hamburger (roof garden)	8th and Broadway		
Scientific Exhibit	Hamburger (4th floor)	8th and Broadway		
Information, P. O., etc	Hamburger (4th floor)	8th and Broadway		
Practice of Medicine	Majestic Theater	8th and Broadway	Lankershim	7th and Broadway
Nervous and Mental Diseases	Walker (McKinley)	7th and Grand	Westminster	4th and Main
Diseases of Children	Walker (Lincoln)	7th and Grand	Westminster	4th and Main
Dermatology	Blanchard (Broadway)	3d and Broadway	Hollenbeck	2d and Spring
Pathology and Physiology	Blanchard (Symphony)	3d and Hill	Hollenbeck	2d and Spring
Surgery	Baptist Auditorium	5th and Olive	Alexandria	5th and Spring
Genito-Urinary Diseases	Blanchard (Music)	3d and Hill	Hollenbeck	2d and Spring
Obstetrics	Baptist Aud. (Berean)	5th and Olive	Hayward	6th and Spring
Preventive Med. and Public Health	Hamburger's	8th and Broadway	Alexandria	5th and Spring
Pharmacology	Walker (Garfield)	7th and Grand	Lankershim	7th and Broadway
Ophthalmology	Parish (2d floor)	6th and Olive	Van Nuys	4th and Main
Laryngology and Otology	Parish (1st floor)	6th and Olive	Angelus	4th and Spring
Stomatology	Dental College	5th and Wall	King Edward	5th and Los. A.

[The Local Committee on Arrangements sends the above schedule of meeting places and of the hotels designated as headquarters.]

This committee feels very strongly that in order to awaken similar interest among women all over the country, the cooperation of physicians is absolutely necessary. Physicians are the properly qualified people to discuss the dangers of disease, as well as to teach the lay public the principles of health in a rational and scientific manner. The lay public must understand these principles if we are to have an advance in the control of venereal disease. The principles of ignorance on matters of health and disease have been the methods of the past and have served us very poorly.

The committee has sent out letters to all state federations of women's clubs requesting them to urge the clubs in their federations to have at least one meeting during the months of March and April on the subject of social hygiene, advising them to apply for speakers to the physicians in their locality.

The committee has also suggested that the following outline be substantially adhered to by the clubs: (1) How prevalent is gonorrhea? (2) How is it contracted and communicated? (3) What are its dangers to mother and child? (4) What is its treatment and how can it be exterminated? (6) How prevalent is syphilis? (7) How is it contracted and communicated? (8) What are its dangers to mother and child? (9) What is its treatment and how can it be exterminated?

This apparently extreme outline for lay clubs is deemed necessary because the temptation to dodge the real issue is too great.

It is hoped that the physicians in each community will respond to the request on the part of women's clubs for such lectures.

RACHELLE S. YARROS, M.D.,
Chairman Social Hygiene Committee of the General Federation of Women's Clubs.

The Septic Tank

To the Editor:—THE JOURNAL, Dec. 10, 1910, contains an editorial on the septic tank in which there is a quotation from the well-known sanitary engineer, Mr. Rudolph Hering. The quotation does not fairly represent Mr. Hering's views, and the general trend of the editorial is hardly in keeping, apparently, with the present state of engineering thought.

It is true that the former septic tank has proved a disappointment; it is true that the sludge so treated is often more difficult to manage than the untreated sewage; it is true that not unfrequently the rising sludge breaks up the scum, and creates a disagreeable condition; but it is not true that the septic tank idea is being abandoned.

In the Emscher Valley, in Germany, there is a sewage district of 308 square miles, containing a population of about 2,000,000 persons, and the population is rapidly increasing. Dr. Ing. Karl Imhoff, of Essen, is the Chief of the Sewerage Department (*Abwasserabteilung*) of the Emschergenossenschaft. The Emscher, or, as it is more frequently called, the Imhoff tank is proving thoroughly satisfactory. In that German district there are seven now in operation, serving 250,000 persons. Ten more are being built, and thirty additional tanks are projected for the district. In America, a trial tank has been in operation for some time at Philadelphia, and another is located at the Thirty-Ninth Street testing station of the Chicago Drainage District. A large tank is under construction at Holmsburg, near Philadelphia, and another is being built to care for the entire sewage of Atlanta, Ga. According to a recent number of the *Municipal Engineer*, Erie, Pa., is to construct one, on the advice of Mr. Hering. Similar tanks have been advised for Batavia and Oswego, N. Y.

In the *Engineering News*, Dec. 1, 1910, Mr. Hering says: "It was apparent to me that the sludge question, which had been the *bête noire* for 30 years, was nearing a satisfactory solution. The Imhoff tank, based on what had appeared to me a rational principle, was completely fulfilling its promises of two years before by transforming the compacted suspended matter into inoffensive humus material. The reason for this inoffensiveness was a complete digestion under favorable conditions, of all the material that usually becomes foul."

The gases arising are approximately 75 per cent. marsh gas, and 25 per cent. carbon dioxid. (In the articles of Dr. Imhoff in the *Engineering Record*, and by Hering and Saville in the *Engineering News*, the carbon dioxid is called monoxid, but in a private communication to me Dr. Imhoff corrects the misstatement.) Saville says that it has only been necessary to remove the sludge from some of the tanks once or twice a year. In others it was done more frequently. The removed sludge is inoffensive, and when spread on the drying beds becomes spadeable in from one to four days.

The test tank in Chicago is by the side of the Dortmund test tank. The effluent from each is perfectly clear, but whereas that from the Dortmund tank is very offensive, on account of the large amount of hydrogen sulphid contained, that from the Imhoff is as sweet as spring water.

The drying bed for the Bochum, Germany, plant, which cares for the sewage of 145,000 persons, is only half an acre in size, and the entire sewage of Schwerin, Mecklenburg-Schwerin, is treated within sight of the ducal palace, without offense.

HENRY B. HEMENWAY, M.D., Evanston, Ill.

[COMMENT:—We are at a loss to understand the statement in the first paragraph of the above communication regarding the views of Mr. Hering. If Mr. Hering's own words do not represent his views, we cannot understand why he should have written them or whose views they do represent.

As regards the Imhoff tank, our correspondent is evidently unfamiliar with the history of septic tank treatment, with the characteristics of the Imhoff tank itself and with current nomenclature. The Imhoff tank, as is well-known among sanitary engineers, is so arranged that the sewage with which it is filled is not allowed to reach a "septic" condition. The Imhoff tank is ordinarily spoken of as a purification tank or, as Mr. Saville calls it in the article cited by Dr. Hemenway, "strictly speaking a clarification tank." The distinction between the Imhoff tank and what for many years has gone under the name of septic tank is clear and sharp, and is thoroughly understood by practical workers in this field. —EDITOR.]

Encouragement of the Nostrum Evil by "Reputable" Physicians

To the Editor:—Permit me to ask a question. Why is it that medical men of repute will write articles for so-called medical periodicals whose advertising pages are reeking with advertisements of the worst nostrums, the very kind that the presumed leaders of the profession have set their faces against? I have before me a sample copy of such a periodical making a specialty of surgery. The leading article is written by an eminent surgeon of Baltimore, who specializes in gynecology. What are we to think about such doings? If he is of the rank and file that fight the nostrum evil, why does he not write only for such periodicals as have taken up this fight?

A. E. CONTER, M.D., Apalachicola, Fla.

[COMMENT.—We do not know why reputable physicians will write for such medical journals as those described by our correspondent. Probably for the same reason that equally reputable men will allow their names to appear as "associate editors" or "collaborators" in connection with the same kind of journals. The most disheartening phase of the fight for decency and truthfulness in medical advertising is the apparent indifference, on the part of many physicians of high standing, to the character of the advertising found in medical journals for which they subscribe and to which they contribute. As has been stated time and again in THE JOURNAL, if physicians would insist that the journals they patronize shall be as clean in their advertising pages as they are in their editorial pages, the evils connected with the "proprietary" business would be solved in six months. So long as the leading members of the medical profession give financial support—as subscribers—and moral support—as contributors—to those medical journals whose advertising pages are a disgrace to medicine, so long will the great American fraud—as it relates to the medical profession—flourish. So long, too, will these journals that are trying to be decent labor under a grievous disadvantage.—EDITOR.]

Queries and Minor Notes

Anonymous Communications will not be noticed. Every letter must contain the writer's name and address, but these will be omitted, on request.

WANTED—FICTION EXTOLLING THE AIMS OF PHYSICIANS

To the Editor:—Kindly send me the names of books—modern fiction—in which the aims and ideals of modern physicians are extolled. Monte Stern, M.D., South St. Paul, Minn.

Answer.—To reply to our correspondent's query with anything like completeness would require much time and original investigation. It would be well worth doing, however, and we suggest the subject as an inviting one to some physician with literary tastes. If our readers will inform us of books which they have found worthy of commendation along this line we will make up a list and print it in this column for the benefit of all. Such a list will doubtless be of service, as a suggestion for gifts, for placing on reception-room tables, and for the leisure reading of persons interested in the lives of physicians, etc.

THE MANDELBAUM TEST IN TYPHOID FEVER

To the Editor:—Will you kindly publish in your department of Queries and Minor Notes the method of carrying out and the value of Mandelbaum's test in typhoid fever? E. D. W.

Answer.—Mandelbaum's method for rapid and early differentiation of typhoid was described in The Journal, March 5, 1910, page 827, with illustrations of the pipettes used and of the negative and positive reactions as observed in the hanging drop. Corroborative testimony as to its value was mentioned in The Journal, Aug. 6, 1910, page 543, and a few other writers since have endorsed its value, especially for detection of healthy bacillus-carriers. It does not seem to have been given much of a trial in this country to date.

TUBERCULOSIS SANITARIUMS—PUBLIC AND PRIVATE

To the Editor:—Can you supply me with a list of the tuberculosis sanitariums in this country, both private and public? Walter Rittenhouse, M D., Lake Geneva, Wis.

Answer.—A book entitled "The Campaign Against Tuberculosis in the United States, Including a Directory of Institutions Dealing with Tuberculosis in the United States and Canada," may be obtained from Dr. Livingston Farrand, 105 East Twenty-Second Street, New York City. This is a cloth-bound book of 467 pages and gives much other information besides that mentioned in the title. The price is $1.

REMOVAL OF IMPACTED CERUMEN FROM THE EAR

To the Editor:—The removal of hardened wax from the ear is often a tedious matter, because of the time required to soften it with the usual solution of soda, glycerin and water. I have found that a mixture of acetic acid 1 part and water 3 parts has no injurious effect and will soften the wax *very quickly. It may* be dropped in and allowed to soak, or used with a syringe in large quantities. A. T. Blachly, M.D., Woodstock, Ore.

Answer.—Hydrogen dioxid is another efficient agent. It should be dropped carefully into the ear, with due regard to the pressure that may be caused if the escape of the resultant foam is hindered.

The Public Service

Medical Department, U. S. Army

Changes for the week ended March 4, 1911.

Wolven, Homer F., D.S., reports for temporary duty at Boise Barracks, Idaho.

Ford, Joseph H., major, ordered to duty with troops from Fort Wadsworth, N. Y., to Fort Crockett, Texas.

Stallman, George E., D.S., granted three months' leave of absence about June 15, 1911.

Woodbury, Frank T., major, granted leave of absence for one month and ten days, about April 21, 1911.

Dean, Elmer A., major, granted leave of absence for one month, about March 1, 1911.

Wheate, J. Marshall, M.R.C., orders to proceed to the Philippine Islands for duty is revoked.

Wheate, J. Marshall, M.R.C., relieved from duty at Fort Lincoln, N. Dak., and ordered to Boise Barracks, Idaho, for duty.

Clarke, Joseph T., lieut.-col., assumed temporary charge of office of chief surgeon, Department of the Columbia, and as attending surgeon, department headquarters.

Welles, E. M., Jr., lieut., ordered to proceed from Army General Hospital, San Francisco, to Presidio of Monterey, Cal., for temporary duty.

Kremers, E. D., lieut., left Presidio of San Francisco, en route to San Francisco, for duty as surgeon, U. S. Army transport *Buford*, during the trip to China and return.

Field, Peter C., major, relieved from duty at Fort Slocum, N.Y., and ordered to Philippines division for duty on the transport sailing from San Francisco about June 5, 1911.

Miller, Reuben B.; Eastman, William R., and Hall, James F., captains, ordered to Washington, D. C., on May 22, 1911, for examination to determine their fitness for promotion.

Stallman, George E., D.S., ordered to Fort Clark, Texas, for temporary duty.

Kellogg, Preston S., M.R.C., granted leave of absence for one month.

Qualls, Guy L., M.R.C., recently appointed, is ordered to Jefferson Barracks, Mo., for duty.

Connelly, Philip B., M.R.C., recently appointed, is ordered to Fort Monroe, Va., for duty.

Mitchell, Leopold, M.R.C., recently appointed, is ordered to Washington Barracks, Washington, D. C., for duty.

Baker, Frank C., major, left Fort Moultrie, S. C., on tour of inspection of Medical Department, North Carolina National Guard.

Newlove, George, M.R.C., reports arrival at Fort Sam Houston, Texas, for temporary duty in the field.

Myers, William H., M.R.C., reports for temporary duty at Fort Moultrie, S. C.

U. S. Public Health and Marine-Hospital Service

Changes for the fourteen days ended March 1, 1911.

White, J. H., surgeon, granted eighteen days' leave of absence from Feb. 16, 1911, without pay.

Earle, B. J., P. A. surgeon, granted ten days' leave of absence from March 1, 1911.

Lloyd, B. J., P. A. surgeon, directed to proceed to Spokane, Wash., on special temporary duty, Feb. 28, 1911.

Creel, R. H., P. A. surgeon, directed to make such trips as may be necessary in investigation of oyster beds of Virginia, Feb. 17, 1911.

Turnipseed, D. C., asst.-surgeon, directed to proceed to Manila, P. I., and report to chief quarantine officer for duty, Feb. 16, 1911.

Stiles, C. W., professor of zoology, detailed with the mine rescue car of the department of the interior on special temporary duty Feb. 14, 1911.

Allan, A. Smith, A. A. surgeon, granted seven months' leave of absence from April 1, 1911, without pay.

Hasse, P. F., A. A. surgeon, granted seven days' leave of absence from Feb. 11, 1911, under paragraph 210, Service Regulations.

McLarty, A. A., A. A. surgeon, granted thirty days' leave of absence from Feb. 25, 1911.

Schug, F. J., A. A. surgeon, granted thirty days' leave of absence from Feb. 18, 1911.

Storrs, H. R., A. A. surgeon, granted thirty days' leave of absence from March 1, 1911.

Wood, J. E., A. A. surgeon, granted fifteen days' leave of absence from Feb. 24, 1911.

Society Proceedings

COMING MEETINGS

American Medical Association, Los Angeles, June 27-30.

Alabama, Medical Society of the State of, Montgomery, April 18.
Am. Assn. of Pathologists and Bacteriologists, Chicago, April 14-15.
American Gastro-Enterological Assn., Philadelphia, April 19-20.

South Carolina Medical Association, Charleston, April 19-21.

CONFERENCE ON MEDICAL EDUCATION AND ON MEDICAL LEGISLATION OF THE AMERICAN MEDICAL ASSOCIATION

Seventh Annual Conference, Held in Chicago, March 1-3, 1911

Dr. Arthur Dean Bevan in the Chair

Dr. A. D. Bevan stated that as chairman of the Council on Medical Education of the American Medical Association he had for seven years made a special study of medical education including the conditions in foreign countries. From this study the following conclusions may be drawn: First, medicine has to-day a science just as chemistry and physics are sciences. The art of medicine to-day rests as firmly on a scientific basis as does the practical application of chemistry and engineering, and as there can be but one science of chemistry, so from now on there can be but one science of medicine. The fads and "pathies" that existed under the old empirical practice of medicine become impossible in the light of modern scientific medicine. A thorough training in the sciences on which medicine is based is now essential and a thorough familiarity with disease processes in the living patient must be mastered before the student is permitted to begin practice.

A close analysis of all the facts and a careful study of the results arrived at in other countries leads to the conclusion that the minimum amount of training which will make of a medical student a safe practitioner of medicine is the following: After graduating from high school he should have at least one year of training in physics, chemistry and biology; two years in the science of anatomy, physics, pharmacology and pathology; two years in the study of medicine, surgery, obstetrics and the specialties, with the opportunity of studying these subjects in the dispensary and hospital, and lastly a year's practical training as an intern in a hospital.

The program of this conference has been framed for the purpose of presenting in detail this conception of the essentials in modern education. I hope that as a result of this meeting the medical schools and the state boards represented will use all the influence in their power to secure, as soon as possible, the adoption of these requirements in their own schools in their own state.

Progress and Needs in Medical Education

DR. N. P. COLWELL, Chicago, Secretary of the Council on Medical Education: Changes for the better in medical education have been particularly rapid since 1904 when the Council on Medical Education was organized. Up to that year the number of medical colleges continued to increase regardless of the frequently published references to the overcrowded condition of the profession and reports showing the need of better rather than of a larger number of medical colleges. The increase in number continued until in 1904 the maximum of 166 medical colleges was reached, constituting practically half of the world's supply.

Since 1904, however, there has been a decrease in the number of colleges until now the number has been reduced to 129. Of the forty-four colleges closed since 1907, twenty colleges were closed outright, and twenty-four by merging with others. This decrease has been due to the closing of weak and inferior colleges, or by the merging of two or more medical colleges, forming in each instance one invariably stronger and better equipped college. Instead of a serious matter, therefore, this decrease in the number of medical colleges has been of positive benefit, resulting as it has in the formation of fewer but better colleges.

Since 1904 there has also been a decided advancement in the standards of admission. Until 1904, only three or 1.9 per cent. of all medical colleges were requiring for admission more than a high-school education, but now 41 or 31.8 per cent. (nearly one-third) of all colleges are requiring for admission one or more years of collegiate work, and the teaching of medicine as a whole has been placed more largely on a university basis.

In the last seven years, however, other radical improvements in medical education have taken place. College terms have been lengthened, new methods of teaching have been adopted, more salaried teachers have been employed, more endowments secured, new buildings erected, better laboratories and laboratory equipment installed and better hospital connections and clinical facilities secured. In the last year, several of the larger medical schools have received large donations, have been thoroughly reorganized, have built teaching hospitals, and have adopted higher standards of admission. And reports of other similar changes of importance have continued to come in.

Under the methods and conditions which still exist, there is scarcely any person so ignorant that he cannot gain admission to some medical college. So long as an applicant can pay the required fee, there are still colleges which are only too glad to accept him regardless of his lack of preliminary education. The low-standard colleges referred to can exist only in states where the laws regulating the practice of medicine are inadequate or are not enforced.

The solution of many of the problems of medical education rests in the hands of the state licensing boards and doubtless will be solved by them if they are given a fair chance. In many of the states, the medical boards are seriously handicapped. In the first place, as a rule, the board is too closely connected with politics, and in some states the members are appointed largely for political reasons, and are liable to be changed with every turn of politics. It is often difficult, therefore, to get good men to accept places on the board. In several states, the board is not given full authority in the premises. Either it is hindered, because of a very poor practice act, or the authority is limited or divided by the establishment of special boards for the various medical sects, which make impossible a satisfactory regulation of the practice of medicine. In the fifty states and territories of the Union there are eighty-three different licensing boards—counting the osteopathic.

At most, there should be but one board in each state; that should be a permanent board and should be composed of men appointed for their particular skill in the examining and licensing of physicians, and not for political reasons. If possible, the board should have a permanent secretary who is selected by the board and who is not subject to removal with every change of governors.

Not only should there be but one board in each state, but there should be a single educational standard to which every applicant for license to treat the sick, by whatever means or method, should comply. Let there be but one portal of entry to the practice of medicine. All who are to treat human ailments, no matter whether they are regulars, homeopaths, osteopaths, or the followers of any other school, are alike in that they must make a diagnosis; they must be capable of differentiating between the various diseases in order to treat intelligently the patients who may come to them.

Entrance Examinations

DR. THOMAS S. FISKE, Secretary of the College Entrance Examination Board, New York City: Certain classes of men may be admitted to the study of medicine with comparative safety on the basis of credentials issued by their former teachers. These are: (1) college graduates and students who have completed at least a part of a college course, when they can present credentials issued by some college in good standing showing that they have studied physics, chemistry and biology, in addition to the fundamental elements of an ordinary education; (2) graduates of accredited high schools, who have completed a four-year course in which the subjects just mentioned have been included. The North Central Association of Colleges and Secondary Schools, like several other similar associations, has prepared a list of accredited high schools whose credentials are recognized by a large number of colleges and universities. In addition to candidates belonging to the two classes already specified and able to present satisfactory credentials, there are numbers of young men who every year demand the privilege of being admitted to the study of medicine. In this number will be: (1) college men and high-school graduates whose credentials do not cover all the required preliminary studies; (2) candidates from unaccredited institutions, that is, from colleges and schools which have not received the privilege of issuing acceptable credentials; (3) candidates of irregular preliminary education, such as those who have been prepared by private tutors, have studied in correspondence schools or in extension courses, or are self-taught. In this irregular class will be included naturally all students who have attended accredited high schools without completing the school course.

Standing at the point of contact between the secondary school and the college, the fundamental principle first in order of importance is that of cooperation between school and college. The board represents a cooperation between the colleges on the one hand, and the secondary schools on the other in respect to a matter of vital importance to both. The secondary schools as well as the colleges have a voice in framing and administering the policies of the board. In the second place, the College Entrance Examination Board does not itself assume power or claim a right to formulate definitions of the requirements for admission to college. In the third place, while the board represents a combined effort on the part of many colleges, it is provided that no college shall surrender its own individuality. Each institution preserves the right to enforce such standards of excellence as it pleases or to make such allowance as it wishes for character and capacity on the part of students applying for admission. The certificate issued by the board states merely that the holder was examined at a stated time and place in specified subjects, and, as the result of such examinations, received the ratings entered on the certificates.

The following manifest advantages of the examinations held by the College Entrance Examination Board are: 1. They are uniform in subject-matter. 2. They are uniformly administered. 3. They are held at many points to meet the convenience of students at one and the same time. 4. They represent the cooperative effort of a group of colleges, no one of which thereby surrenders its individuality. 5. They represent the cooperation of colleges and secondary schools in respect to a matter of vital importance to both. 6. By reason of their uniformity they aid greatly the work of the secondary schools. 7. They tend to effect a marked saving of time, money and effort in administering college admission requirements.

Subjects Included in the Two Years of College Work Required for Admission to Medical Colleges

DR. CHARLES R. BARDEEN, Madison, Wis.: During the two years of college work required by the majority of medical colleges which can afford to maintain high preliminary standards, about half the time should be devoted to physics, chemistry, biology and English. The other half should be divided between the study of foreign languages and one or more non-technical studies such as art, history, economics, civics, mathematics and philosophy. The aim of this preliminary college work should be to produce breadth of view as well as to give some understanding of scientific knowledge and methods

Five-Year Medical Course

DR. J. G. ADAMI, Professor of Pathology, McGill University, Montreal: From an educational point of view the great danger of democracy lies in the fallacy that since every individual has the right to equal opportunities all individuals must be given the same opportunities. As a consequence, precise and cast-iron regulations would become the order of the day, and one fixed curriculum would be laid down as the *sine qua non*, whereby at 10:30 a. m. across the whole continent, from the Atlantic to the Pacific and from the Polar regions to the Gulf of Mexico, in country school and crowded city, the individual who has attained to a certain standard in a certain year of the course is being taught the subject-matter of a particular chapter of a particular book on a particular subject. In medical education, it is essential that there be established a minimum of knowledge, and also a minimum time requisite for the acquirement of that knowledge. The Council on Education of the American Medical Association has accomplished a work, the value of which it is difficult to estimate, in making this recognized, and in establishing what should be the minimum. Nevertheless, this minimum should not be regarded as the optimum, and no cast-iron routine should be established to which every medical student should be subjected. Hence, in speaking of the five-year course in medicine, now in operation in the leading Canadian schools, it is not deemed essential that all the medical schools of the continent should adopt such a course. There might be other medical schools having a similar environment, however, which might obtain the best results educationally by establishing a similar course.

Two main reasons led McGill University, four years ago, to change from the four to the five-year system. The first was to make sure that the students possessed a sound training in the preliminary sciences, biology, chemistry, physics, etc. The second reason was to insure thorough hospital training, and to afford adequate time for clinical work. Since our students came from a wide area in a young country, a certain number possessed no opportunity for instruction in the elementary sciences, and as a matter of economy of effort it was better that McGill should have the supervision of the courses in those sciences, rather than that the students should attend courses not specially devised for medical students. Educationally, the graded course bearing a definite relationship to future teaching is of foremost value. It might be well if the courses in physics, chemistry and biology were not delivered in the medical college itself, but in the laboratories of another faculty; it might also be well if the actual teachers were not medical men. Nevertheless, the teaching of these elementary branches should be given with special reference to the future needs of the student. As a matter of fact it was found possible to give the ordinary medical student as sound and generally useful a course in these preliminary sciences in one year as ordinarily consumed two years in the arts or academic course.

This is not the optimum; the man who desires to do so might well take a complete academic course or to specialize in certain scientific branches. It is necessary, however, to fix a minimum for the ordinary students, the men who at most look forward to ordinary practice, and who constitute the bulk of students in the medical school.

Briefly, the objects in the development of the curriculum at McGill have been: (1) to give a sound course in the preliminary sciences subjects; (2) to make the courses from the third to the fifth year as practical as possible; (3) to observe a natural sequence in the various courses; and (4) to give the maximum of hospital instruction with the freest employment of the wards and of bedside instruction.

Equipment and Instruction of the Laboratory Years

DR. E. P. LYON, Professor of Physiology, St. Louis University School of Medicine: The chief function of a medical school is to make good physicians. The good doctor must be an accurate observer; for training observation anatomy and its related sciences are valuable. He must be a skilful experimenter; chemistry, bacteriology, physiology and pharmacology are preeminently experimental sciences, and each has its peculiar methods and value for medical training. The good physician must further be a man who is able to interpret the facts gained by observation and experiment; all the sciences are valuable as training for this power, but pathology is especially useful. The sciences fundamental to medicine are, therefore, justifiable in the medical curriculum on account of their disciplinary value.

The scientific instruction must be in the hands of professional scientists, not practitioners of medicine. These men must be provided with proper laboratories for teaching and research, with equipment, materials, libraries and assistance. Anything less than this provision is to disregard the model which the school is trying to realize, namely, the good physician.

The laboratory work should be conducted by the professors and not by cheap assistants. If the right men are chosen for heads of departments, the choice of specific equipment may be left to them. The state boards would do well to insist that the colleges have trained instructors, rather than publish lists of required equipment which may or may not be used.

The powers of good observation, experimentation and judgment are necessary for the technical work of the physician. But on account of his intimate relation to the people he needs many other traits which may be summed up as character. The medical school can do little by precept but much by example. The medical teachers should be men of character and culture.

Instruction and Equipment of the Clinical Years

DR. GEORGE BLUMER, Dean of the Medical Faculty, Yale University: The problem of teaching in clinical years is a threefold one. The student should receive a training in the fundamental principles of medicine, surgery and obstetrics. He should also receive a practical training in physical and clinical diagnosis and surgical technic and should have an opportunity to apply the principles and technic by actual contact with patients. The proportion of clinical and didactic teaching as methods of imparting fundamental training should be determined by local conditions. There is an unfortunate tendency to overemphasize didactic teaching. On the contrary technical training in clinical and physical diagnosis should be by laboratory methods. There is a marked advantage in the use of living animals in teaching surgical technic. The contact of students with individual patients is the keynote of the fourth year of instruction. A system of clinical clerks is desirable. In regard to the equipment necessary there should be laboratories with sufficient microscopic and other necessary apparatus for each student; a dispensary especially equipped for teaching with abundant material and a hospital especially equipped for teaching under competent medical school control. The greatest needs at present are proper endowment and properly paid and well-trained men in the clinical years. There is also a lack of absolute control of hospitals by medical schools.

DISCUSSION

MR. ABRAHAM FLEXNER, New York City: It is absolutely necessary that the function of passing on preliminary credentials or holding preliminary examinations should be taken away from the medical schools, and in the case of independent medical schools and of medical departments which nominally or actually belong to universities, the entire business of passing on credentials should be handed over to the academic department. Even this latter step will not insure us any more conscientious or intelligent passing on credentials than the medical department is in the habit of giving, and the more one becomes familiar with the details of administration of American colleges and universities, the more one is inclined to think that the medical schools are not in that matter the only offenders. There are very few colleges or universities that handle the subject of admitting students either intelligently or conscientiously. The recent reports of the president of the Carnegie Foundation show that the admission requirements of American colleges are, without exception, largely nominal; that is to say, the conditions are such that students are so freely admitted and the conditions under which they are admitted are such that it is difficult for any institution with which I am acquainted to make clear the precise basis on which entrance conditions are enforced. The remedy and improvement for this condition are more likely to come if we can secure concentrated criticism and publicity regarding entrance records of the American colleges than if the responsibility is distributed among a great many registration offices or township offices largely without any of the necessary facilities for dealing with records intelligently.

DR. CHARLES W. DABNEY, President of the University of Cincinnati: The authors of these papers have thrown light on the difficult problem of medical education from different points of view. One of the most gratifying observations is that wherever we find advanced entrance standards, the colleges having such high standards have prospered and are prospering. That has been true everywhere, and I am delighted with the progress being made in the advancement of medical education. A thought that has come to me in my own experience in the last few years is that we are in danger of making our methods in medical colleges too mechanical, too fixed, and I hope that some one will tell us how we are going to overcome that. I would like to enter a protest against too mechanical requirements. In our institution we are conscientious in the enforcement of entrance requirements. A general thought I would advance is this: in medical schools, as in engineering schools and colleges of liberal arts, we are introducing too many mechanical methods. We want educated men. We want to produce men who can observe and think and reason. Four years is a desperately short time to give a man an education. He can be given a start, and can probably be trained to observe and to think in that short period of time.

DR. VICTOR C. VAUGHAN, Ann Arbor, Mich.: We must not have cast-iron rules in the teaching of medicine; we must have diversity. We must not expect any two medical schools to teach medicine in exactly the same way. The individual teacher must always be given a certain amount of freedom in the management of his department. I do not expect to dictate to the professor on physiology how he shall teach physiology. If he is a capable man, that must be left to him. I recognize that the fifth-year medical course, adopted in the Canadian medical schools, as referred to by Professor Adami, is applicable to, and probably must be adopted by, certain schools in the United States, but I do not believe that it is comparable with the six years combined course. I do not believe it is so good.

DR. HENRY A. CHRISTIAN, Boston: Of the various methods of increasing the curriculum, three general suggestions have been made. One concerns itself with the increasing the required hours within the assigned time. More has been said about that in the past year than this year. The result of that suggestion has been that the curriculum has been crowded. The limit has been reached already. At present, our curriculum needs energetic surgical treatment. In other words, we need to reduce materially the number of subjects taught, and the number of hours of required work. So far as the curriculum is concerned, leaving it as a four-year curriculum, the war cry now should be simplification. A second method suggested of increasing the curriculum has been along the lines of increasing the preliminary requirements of students before they enter a medical school. We have gradually increased the standard of medical education by increasing the preliminary preparation of the medical student. The method of pediatrics can well be applied to that phase of the subject; we should continue to feed the preliminary requirements until students gradually grow to a larger size. It may be that breast milk, or modified milk, will be best for the infant, but the infant at the present time to my mind needs a little more food and a little more growth. A third method suggested of improving the curriculum has been by the addition of a fifth year. Dr. Wesbrook, of the University of Minnesota, proposed that the fifth year shall be a hospital year. In discussing that paper I offered certain objections, not to the student having as much clinical experience as he could possibly get, but to incorporating a fifth year in the medical curriculum and making the medical school responsible for that hospital year.

SYMPOSIUM ON STATE LICENSE

Valuation of Credentials

DR. FRANK B. HILLER, Secretary Missouri State Board of Health: There rests on a medical licensing board a responsibility and duty threefold in character: (1) that highest and greatest duty of safeguarding the public against the unworthy acts of the unqualified who desire to engage in the practice of medicine; (2) the duty of demanding of the institutions teaching medicine and surgery, that these schools and colleges shall so measure up to the standard of equipment and teaching capacity as to permit none to leave their halls with the degree of M.D. except those who are well-rounded and qualified morally and professionally to take their places in the ranks of a profession whose standards and knowledge are advancing with remarkable rapidity of force; (3) that of dealing justly and adequately with the applicant as he appears before such a board, an aspirant to have conferred on him the legal right to engage in the practice of the profession he has chosen. The standards demanded by the board must and necessarily do form the basis from which the valuation is computed, and the quality and uniformity of requirements constitute the rock on which reciprocity suffers injury, and in many instances wreckage. In other words, uniformity of medical requirements and standards exacted by all examining boards in the country is the ideal for which we are working. The agitation by the American Medical Association has brought about many reform methods in the examining boards. The work of the Association necessarily has been along the lines of agitation and education, the Association not having within itself the legal power to enforce the requirements it has advocated. The state examining boards, however, in practically all states, are supported by statutory law enabling them to enforce many or all of the advanced requirements that have been set forth by the Council on Medical Education, and all boards should vigorously assume the responsibility and boldly and justly administer the duties with which they are charged.

Interstate Reciprocity

DR. W. T. GOTT, Secretary Indiana State Board of Medical Registration and Examinations: Under our form of government the physician's license makes him a professional prisoner in the state which granted him his license. If the exigencies of climate, fortune, or business make it necessary for him to change his location to some other state it is necessary that his qualifications be again tested, and he must undergo another examination. Is this right? If the United States is one country and one people, is it fair or reasonable to require a citizen to submit to forty-eight examination tests in order to demonstrate his fitness to practice medicine in this country? Under our form of government by federated states, however, that is necessary unless some plan of interstate agreement can be secured that will in a measure nationalize the licensing of physicians. That plan is by interstate reciprocity by which due weight is given by one state to credentials obtained from a sister state whose requirements and standards are substantially equivalent to those of the state of proposed residence.

Some men hold that such reciprocity agreements cannot be fairly entered into until all states secure uniform practice acts and uniform requirements; and without question such uniform legislation and requirements would be a great advantage to society, to the individual and to the public. However, if no attempt has been made to establish reciprocity relations between states until all states have adopted by legislative enactment uniform medical practice acts, the millennium would have been reached before a single license would have been issued through reciprocity.

In recognition of a strong demand in the profession, some states entered into reciprocal agreements as early as 1901, and at present the majority of states have such agreements with certain other states. Reciprocity in medical licensure, if conscientiously administered, has a favorable influence on educational standards. State practice acts are not apt to be weakened or the standards lowered since that would endanger the reciprocal relations with other states. Medical colleges also are urged to keep their standards high since their students are thereby made eligible to registration through reciprocity in a larger number of states.

So long as cults in the healing art exist, it is a serious mistake, in my opinion, to provide for each a separate board of medical examiners. The administration of such boards is consciously or unconsciously influenced, biased, and unnecessary temptation is put in the hands of such boards to be lax in passing on the credentials of applicants of their own system of practice. The credentials issued by a board composed entirely of representatives of one system of practice should not be acceptable for a certificate through reciprocity and such a ruling would have a salutary effect in upholding the standard of educational qualifications throughout the country.

Examinations

DR. WILLIAM S. FULLERTON, *St. Paul:* The primary object of a state board examination is not to protect the physician against the unlicensed man, but the one and only object for the existence of the state board is to protect the public against the incompetent practitioner of medicine, and on that ground, and that alone, state boards rest. So long as the appointment of a state medical examining board is a political favor for party allegiance, irrespective of selecting the best men for the position, just so long will the public fail in being protected to the degree to which they are entitled. Men appointed on boards of examiners should not be behind those who are teaching the subjects in colleges, and they should not be subject to removal at the end of a short term. They should be chosen on the recommendation of the medical profession to the appointive power. These men should have facilities, both financial and otherwise, for carrying on the examinations.

Discussion on State License

DR. HERBERT HARLAN, Maryland: Are examinations as now conducted the best method of testing a candidate's fitness to practice medicine? I should say, unqualifiedly, no; they are not. I believe that a practical examination is feasible, but not on every subject in every department; but I believe that it can and will be slowly introduced. I recognize that there are many difficulties in the way. The Maryland law says that the examination shall be written, but when we succeed in having the law amended, as we hope to do, practical examinations will be provided for.

DR. G. B. YOUNG, United States Public Health and Marine-Hospital Service, *Chicago:* My experience on an examining board has led me to arrive at the conclusion that a high school certificate is very indefinite as far as giving a reliable test of the candidate's educational fitness to study or to practice medicine is concerned. What we want in education preliminary to study of medicine, as I understand it, is not simply the acquisition of certain knowledge which makes the acquisition of subsequent medical knowledge easier, but such a training of the student's mind will produce a candidate who is intellectually fit to master the problems which are presented in acquiring a medical education, and has ability to apply that knowledge to practice. Is it not worth while for the organized boards to consider the propriety of including in their examination some test or means of ascertaining the definite value to be assigned to the certificates which are presented?

DR. CHARLES H. COOK, Natick, Mass.: Boards of registration in medicine are to protect the public or the citizens of the commonwealth, and the members are state officials, rather than physicians, appointed to those positions, not for the benefit of physicians primarily, but to protect the public. It is a question whether the power of officials of one state can be delegated to the officials in another state. So far as I know, this point has never been carried to the courts. If it were, I would be interested to know what the decision would be.

MR. ABRAHAM FLEXNER, New York City: None of the European countries I have visited—France, Germany, Austria or England—still makes exclusive use of the written examination. Although they all to some extent employ a written examination, the emphasis falls strongly on the practical features. One hears in America many different objections to the introduction of the practical examination. In some instances the laws seem hostile. Whether the law which prescribes a written examination could not really be circumvented, so that a practical examination, so far as the answers go are concerned, can take more or less a written form, I do not know. I should think it not impossible that a little ingenuity expended on that point might bring forth some interesting results and avoid the necessity of recasting the state law. It is alleged, also, that the numbers to be examined in this country are fatal to the introduction of the practical examination. I believe that the Minnesota State Board, for example, is not now embarrassed by the question of numbers. I suspect that any state board now undertaking to examine its candidates practically will find that the embarrassment due to the popularity of the examination will prove decreasingly important. As a matter of fact, if the practical examination were introduced, I believe it would be found that the question of numbers would cut no figure whatsoever. The most efficient practical examination which it was my good fortune to witness was also the largest from the standpoint of numbers, this examination having been held by the Conjoint Board, in London, England.

DR. GEORGE H. MATSON, Columbus, O.: The Ohio State Board has undertaken practical examinations in physical diagnosis. We have now finished three examinations of this kind. The applicants who have appeared before us have been called on to test their ability on patients who were suffering with various cardiac and pulmonary diseases, with enlarged livers and spleens, and some of them with incipient nervous affections, tabes particularly, and one or two patients with hemiplegia. We secured these patients from the county infirmaries and from the dispensaries, and the first exhibition of this practical examination was remarkable. Formerly, we had at our June examination from 240 to 250 applicants, but since we have established practical examinations we are having from 125 to 140.

Universal reciprocity can never obtain for three reasons: first, because universal uniformity can never obtain in medical colleges. Second, universal laws can never obtain in a progressive body of states, and, third, we can never have uniformity in the personnel of medical boards, so that when we speak of having universal reciprocity we can only look in the future to the minimum medical requirement and never to a maximum. Practical examinations are a reality, and not a theory.

Evening Session

Standards and Authority

PROF. GEORGE EDGAR VINCENT, President-Elect of the University of Minnesota: Physicians are rightly regarded as social servants; their skill and fidelity are obviously vital to the community. Yet this view is far from universal. Individuals by tens and thousands see in a medical career chiefly a means of livelihood. They resent the rising standards of medical education as obstacles to the early enjoyment of an income. Many of these individualists resort to short-cut schools and to least resistant states. But these outcasts are embittered by exclusion from prestige in practice. They swell the ranks of the quacks and unfurl the black flag of the medical privateer. The discredited schools and diploma mills also insist on the old dogmas of liberty and *laissez faire*, and make appeals to the traditions of the fathers, the spirit of '76 and other quaintly irrelevant ideas and shibboleths. To the influences which resist the standardization of medical education may be added makers of proprietary remedies whose success varies directly with the credulity of the public. But in spite of impatient selfishness, mental inertia, sincere fanaticism, unscrupulous greed, the standardizing of medical education goes steadily if too slowly on. The association under whose auspices we meet affords an example of that extra-legal centralized organization which creates national institutions amid what often seems a chaos of state particularism. Slowly but inevitably we are selecting a medical élite, experts to whom we entrust a constantly growing body of scientific knowledge and an elaborated technic. If the community for its own protection insists on testing and training its social functionaries, it must provide a way of finding and encouraging unusual ability however this may be circumstanced. A system of scholarships awarded by competent authority after adequate tests and continued only so long as the scholar's work justifies the support would seem to be a socially necessary consequence of the increased demand of medical education. Medical associations, individuals, institutions and the state should all have a share in creating such a system.

Scientific men should face facts as they are. The public mind is like a force of Nature. It is childish to rail at it, to denounce it, to expect it to be docile about technical matters. Physicians should diagnose the condition of the public mind calmly and in a scientific spirit. They should try to trace the play of cause and effect, and then take measures to bring desired results to pass. In this they have the right to ask the cooperation of all thinking men and women. The public is controlled by leaders. These leaders must be informed and intelligent. Colleges and universities have a responsibility in training these leaders. Every institution of higher education should be a model of public sanitation and hygiene. Every graduate should be well-grounded in the principles of personal and community health. The public schools could do much more than they do at present to train children in hygienic habits and in intelligent deference to sanitary regulations. Popular literature, lectures, parent's meetings, visiting nurse associations, organizations like the antituberculosis societies, city and state health departments and boards—agencies of many kinds are all engaged in the work of popular health education. Would that Mr. Carnegie's next $10,000,000 gift might be devoted to publishing in newspapers authoritative advertising bulletins on hygiene and sanitation. Many an editor would be glad to be freed from irksome slavery to the "patent-medicine" men.

Great responsibility for the education of the public must fall on members of the medical profession. Physicians and professors of medicine must devote some time to public addresses, to cooperation with public school authorities, to hearty support of local health authorities when these are reasonably competent, and to civic movements designed to improve a defective public health service.

Movements for legislation affecting medical education, admission to the practice of the profession, the organization of health boards, the enactment of sanitary regulations, etc., should all be regarded as a part of the process by which the expert few and the many are to be brought into relations of mutual respect and good will.

The State and Medical Education

PROF. WILLIAM L. BRYAN, President of Indiana University: The first appropriation of public funds for medical education in Indiana was made within the past thirty days. The schools of medicine have come together. Aside from the two-year school at Valparaiso, for which I wish to say a good word in passing, we have now in Indiana one school of medicine, and that is a department of the state university. The sects have come together on the terms of the law governing the medical schools. The language of the statute is as follows:

> That there shall be no discrimnation for or against any school or system of medicine in the university, and that all or each of the schools or systems of medicine now recognized by the state shall have adequate opportunity to teach the practice of medicine in the university according to the principles advocated by them respectively, and that it shall be the duty of the trustees of Indiana University to provide such instruction in as thorough a manner as the means at their disposal will permit, and as nearly as possible to provide the same quality of instruction whenever a reasonable demand shall be made for the same.

Everybody agreed to that. The university holds the doors of the school hospitably open to every variety of medical theory on the conditions set forth in the law. Up to this time no particular school of medicine has taken advantage of this law.

The Responsibility of State Universities in Public Health Matters

PROF. GEORGE E. MACLEAN, President, State University of Iowa: A college of medicine first should turn out well-prepared practitioners, not simply to cure disease, but educated as sanitarians, and conscious that the medicine of to-day must lend itself to the science of preservation and health and prevention of disease. The practitioner must be more than a mere medical man. He must be a citizen, and with large functions for society. He, therefore, will study in the university psychology, sociology, philanthropy, social pathology. Experience shows that he ought to know something of political and economic science, for more physicians break into the legislature than into the penitentiary. The state board of health should find the highest expert service, free from all political contamination, in the men of laboratories of the State University. The university students, and especially the medical students, should have the benefit of these health experiment stations, for enlarging the scope of their undergraduate education, and in order to be trained for sympathetic cooperation with the health authorities and the university as they settle in their professions throughout the state.

The Board of Control in Iowa is charged with inspection of poor-houses, and even of private eleemosynary institutions, and the state board of health with inspection of hospitals, maternity and children's homes. This accepted responsibility by the state opens the door when correlation of all the state bodies is effected, for the university to aid by its experts, and to make all these institutions in some sense adjuncts to the university laboratories. A federation of the hospitals, public and private, with the university, which might furnish interns, would not only give a proper extension of the course in medicine, but would disseminate missionaries of public health. Most naturally, the university becomes as much of a coordinating point in sanitary matters as it is in educational affairs.

Impressed by our opportunities and the vision of the future possibilities of public health, we put up the prayer to you medical men: "Come over into Macedonia and help us."

The original Macedonian cry was a missionary call and a crisis in civilization when the Occident turned to the Orient for the life of Christianity. At this moment, according to Edward A. Woods, America is awakening to the realization that the chief wealth of her country is not in its material resources, but in the lives and health of its people. The lives of a nation, according to the insurance men, are worth three times its property, or over three and one-half billions of dollars. In the light of the inestimable worth of life in a nation with a Christian faith, how great our responsibility in this tremendous public health movement now just starting to conserve health and even lengthen life!

JOINT CONFERENCE ON MEDICAL PRACTICE ACTS

Medical Practice Acts and the Public

Hon. Edward J. Brundage, Corporation Counsel, City of Chicago: Notwithstanding the vastly greater importance of the public health, all requirements for the practice of medicine have been left by the people to the physicians themselves. While watchful over the possession of things material, the people have been careless in their dealings with the most precious of all assets—good health. If unfit men are practicing medicine in this day, the fault is not with the profession, but with the public that permits quack-producing conditions to exist. There has been a great advance in the last decade in the standard for the practicing of medicine, and physicians are entitled to the credit for raising the standard. The public, through ignorance or lack of understanding, has contributed little toward helping physicians in this work. The state of the public health is dependent on the progressiveness of the medical profession, but the profession is not responsible if the public is lax. Some of the people have become aware of this situation, but the vast majority are still unable to discriminate between physicians properly trained and those untrained. The title of doctor is the most abused of all. In its common use it signifies nothing as a title of learning or distinction. Doctors are of as many varieties as the product of a pickle factory. The thing essential for the protection of the public is some way to discriminate between men bearing the title. In my judgment a man of training, high education and character, ought to possess a title distinguishing him from the man who treats the diseases of animals or practices chiropody. But one course appears to the layman to protect the public against such incompetency, and that is to raise the standard of admission to medical colleges by requiring a preliminary degree in arts or sciences as a prerequisite. Even then, after graduation, no license should be granted to practice medicine or surgery until actual experience in a hospital or similar work has been obtained, for a sufficient period to demonstrate ability.

The best evidence that the public is becoming aware of the importance of the physician to the welfare of the community is the growing demand for the creation of a national department of health. Problems in matters of health are constantly being created with the rapid growth of urban life. Medical science is taxed to its greatest capacity to obviate the danger caused by the massing of people in restricted areas. No branch of science has progressed so rapidly, no profession contains more thinkers, willing to devote their lives to the betterment of mankind. The public is learning more and more to depend on physicians, and I am sure the progressive men of the medical profession will find increasing support from the public at large.

Attitude of the Judiciary in Enforcement of Medical Practice Acts

Judge Jesse A. Baldwin, Appellate Court, Chicago: The medical practice acts in the various states have been vigorously contested on the ground of alleged unconstitutionality. A proper consideration of the basis on which such legislation rests readily discovers satisfactory reasons why the courts, in more than thirty of the states where the legislation was directly attacked, have distinctly sustained the constitutionality of such legislation. With the medical practice acts varying, as they do, in the several states, and with supreme courts, and in many instances appellate courts, in each of the states, it is not surprising that there should be a lack of absolute uniformity either in the legislation or in the decisions of the courts under it. It is difficult to draw any conclusion as to the attitude of the judiciary in the enforcement of medical practice acts from the decisions, and yet examination makes it safe to say that so far as they are criminal statutes, enforcible by fine and imprisonment, the courts are required by the accepted canons of construction to construe them strictly, but examination also shows that both the judiciary and the medical fraternity are applying a progressive science.

While possibly the courts are even more conservative, and more subservient to precedent than the medical profession, no one, after a careful review of the situation, can deny that even the courts are affected by new and progressive views and constructions which are, by changed conditions and necessities, made applicable to the case under consideration. The statutory regulations in regard to the practice acts must be adopted in good faith, must be reasonable, must operate equally on all alike, must prescribe qualifications reasonably possible of attainment by study and character, and fairly intended to protect the public against fraud and imposition. If these requirements are met, the acts will be sustained by the courts, even though the conditions are rigorous, and though sometimes the provisions are not such as the court would itself deem the wisest.

"Let me urge you to move forward unitedly, and secure in the interests of suffering humanity the strongest and best legislation possible; continue in your efforts to compel higher standards in your profession, subordinating selfish interests to the public good, and be assured that the attitude of the judiciary in the enforcement of legislation enacted under such conditions and to embody such purposes will be cordially sympathetic."

What Should be the Attitude of the State Toward the Practice of Medicine

Dr. M. L. Harris, Chicago: The only justifiable pretext for a medical practice act is that it shall protect the people against ignorance and incompetence on the part of those who treat the sick. It was thought that this might be accomplished by prohibiting anyone from practicing medicine who had not been licensed so to do, and in not licensing anyone who had not proved himself qualified. A law carefully drawn up on these lines and strictly enforced would undoubtedly restrict the practice of medicine to those qualified. But none of the acts so far passed adhere strictly to this plan nor are any of those which closely approximate it strictly enforced. The state should not attempt to restrict the practice of medicine to a particular class, but should designate those who are competent so that the public may be able to distinguish between the competent and incompetent. Joined to this duty of guidance is the equally important duty of protection. None but qualified physicians should be eligible to any medical position in the public health service, or in any public or charitable institution under the control of the state or any of its municipalities. As all contagious diseases are a menace to the public, and as most of them should be reported to the proper health officers, no unqualified person should be permitted to treat or to assume the medical care of people suffering from these diseases. All parents, guardians and institutions having minors under their care or control should be obliged to furnish them with qualified medical attention in case they are sick or injured and require it. No death certificate should be accepted by the authorities unless signed by a qualified physician. In this manner the state will be able to carry out its duty of protection.

The restrictive or licensing plan of regulating the practice of medicine is fundamentally wrong in principle in that it makes the state dictatorial in a matter of personal rights which is best left to the thinking individual.

Regulation of the Practice of Medicine for the Public Good

Mr. Charles R. Henderson, Professor of Sociology, University of Chicago: Studies and experience disclose the necessity of training in purely scientific investigation. Every advance movement in public hygiene must start from a new laboratory revelation, as the control of diphtheria, typhoid, tuberculosis, summer diseases of infants. Not all, not even a majority of physicians, can be pioneers, but every one should have the fundamental discipline which will make him intelligent and sympathetic toward the investigators. The educated physician is needed to save the nation from quackery which fattens on popular ignorance and inherited superstition. The "patent-medicine" vendors and the faith-healers thrive because science is not a common heritage. The alcoholic superstition owes its survival partly to the want of unanimity among doctors. Free competition in each calling has limits of usefulness. A physician's "trust" is desirable on certain conditions: it must admit all who are competent; it must use fair tests to exclude all others; its charges must not be prohibitive to the poor. Some affect to fear that examinations will snuff out some spark of genius; but the criticism of scholars is a guarantee that no valuable idea will be lost. Indeed, the higher the standard of state examination, the more certain it becomes that every possible hypothesis will be adequately tested by men who try their experiments cautiously on animals before they take too great risks with human patients.

The Administration of Medical Practice Laws

Dr. A. B. Brown, Secretary Louisiana State Board of Medical Examiners: In order for the Board of Medical Examiners to administer usefully the functions that should belong to such a board, it is essential that there should be legislative authority broad enough to permit the board to cover the entire field of regulation of practitioners of medicine. Such a statute must not be too strict in limiting the power of such board. It is humanly impossible for the author of a statute of this nature to foresee all the possible changes that may occur in connection with the development of medical science. The definition of the practice of medicine must be comprehensive. It must enable the board to reach every person who professes to cure disease, or to remedy defects in human beings, or to relieve physical pain or to rectify mental aberration. As a prerequisite to the right to take examinations, the statute should require the presentation to the board of examiners of a diploma, or equivalent certificate showing that the candidate had completed, to the satisfaction of the medical college issuing it, his course in said college; said diploma or equivalent certificate must be issued by a college the requirements of which are satisfactory to the board. The standing of each college must be left to the judgment of the board of examiners. There can be no other judge of the collegiate standing than the board. The legal procedure by which the law is to be enforced should be such as to render the board independent of any local influences that might attempt to obstruct the provisions of the board.

Financing of State Board Work

Dr. Herbert Harlan, President, Maryland State Board of Medical Examiners, Baltimore: The objection to the financing of state boards by the state, is the difficulty in arranging for a liberal expense account under the control of the board. For example, would the average controller pass the voucher for *per diem* and traveling expenses of a representative of a a board to attend such a meeting as this one? Again, the state law officers would surely be expected to act as counsel in defending suits and pushing prosecutions. Many state's attorneys have shown themselves to be, if not hostile, at least very indifferent in regard to enforcing medical practice acts. In Maryland we had great difficulty on this point even though we have our own attorney to aid us. It is my opinion that the best results would come from leaving the distribution of the funds entirely with the boards. In certain states, where the amount is large, larger than is needed for all expenses and for reasonable compensation of the secretary and members, as the money all comes from the physicians, there could be no serious objection to having the surplus turned over to the uses of the state medical society.

CONFERENCE OF THE NATIONAL LEGISLATIVE COUNCIL

The chairman, Dr. H. B. Favill, appointed the following committee on resolutions: Dr. E. J. McKnight, chairman, Hartford, Conn.; Dr. A. B. Brown, New Orleans; Dr. R. M. Funkhauser, St. Louis; Dr. Charles F. Whithington, Boston; and Dr. Frederick R. Green, Chicago, secretary of the Council on Health and Public Instruction, ex officio.

Dr. F. R. Green, Chicago, presented his report, after which there was a roll-call by states and presentation of reports from state representatives. There were also reports from interim committees, Carroll memorial, medical expert testimony and optometry.

Report of Committee on Optometry

Dr. John C. Bossidy, Chairman, Boston: Twenty-four states had legalized optometry by the end of 1909; or, as opticians claim, had recognized it as a profession. In 1910 physicians vigorously fought the further extension of this pernicious measure, and the opticians were beaten in every state where they made their effort. The committee finds apathy on this subject in the medical ranks. The fight in the past has been by a few medical men, and this state of affairs should be remedied. Columbia University, of New York, was persuaded during the last year to establish a course in optometry. The university prescribed a minimum of twelve students before starting the course. The result of the establishment of this course has been that Columbia University has been quoted in many states as the chief argument for the establishment of further optometry laws; and yet, with all this effort, there were on the first of February of this year, but eleven students taking this course. The committee is impressed with the great harm that can be done to the public through unwise legislation, and its members hope that every medical man present at this conference will see this subject in all its present and future dangers.

Educational Work in Vital Statistics

Dr. Cressy L. Wilbur, Chief Statistician, Bureau of the Federal Census, Washington, D. C.: One of the chief assets of the Bureau of the Census in its work of endeavoring to promote the better registration of vital statistics in the United States is the continued earnest cooperation of the organized medical profession. Nothing could be done if the physicians of the United States were opposed to the enactment and enforcement of effective registration laws, and practically all that has been done to secure such legislation has been through the active efforts of the medical profession. The registration service in the United States is too often treated as merely clerical or the mechanical part of public health organization and entrusted to utterly incompetent hands. The result may be exceedingly disastrous when the health officer undertakes to test his work by the use of vital statistics, and in general it may be said that all sanitary workers in this country are hampered by the lack of uniformity and thoroughness in statistical publications; hence the desirability of building up, with its roots in the broad scheme of medical education, a body of trained practical workers in vital statistics and appreciative students and users of their results. This object is nearer to accomplishment than ever before, but it will take many years of earnest cooperative effort on the part of these councils of education and legislation, with the full support of the entire profession before we shall bring this neglected subject up to the full measure of its usefulness.

REPORT OF COMMITTEE ON RESOLUTIONS

The Committee on Resolutions presented the following report, which was adopted:

Whereas, The Committee on Carroll Memorial has completed its work in a highly satisfactory manner to all concerned; therefore, be it

Resolved, That the final report of the committee be accepted and the committee discharged; and be it further

Resolved, That the committee recommends that the cordial thanks of the conference be extended to Major Ireland and his committee for the efficient manner in which they have accomplished their work

Resolved, That the thanks of the conference be extended to Drs. Halsey, Gay and Bristow for their individual efforts in the consideration of medical expert testimony, and that this committee be discharged; and, be it further

Resolved, That the Council on Health and Public Instruction be requested to establish a standing committee to give this matter thorough consideration and, if possible, to confer with a committee of the American Bar Association.

Resolved, That the Seventh Annual Conference of the American Medical Association on Medical Education and Medical Legislation deplores the action of Columbia University, of New York, in establishing a course of study in optometry, for the reason that opticians have never succeeded in founding an official school of optics or optometry, but have relied on the recognition or legalization of the word optometry to make them a profession, and for the further reason that the existence of such a course at Columbia University has this year been used in many states as the chief argument for the further enactment of optometry laws, which are designed to permit opticians to practice medicine in a limited degree; and, be it further

Resolved, That a copy of these resolutions be transmitted by the secretary of the conference to the president of Columbia University of New York.

Resolved, That this conference reaffirms its endorsement of the model bill on vital statistics and expresses its appreciation of the interest shown by Hon E. D Durand, director of the census, and by Dr. Cressy L. Wilbur, chief of the division of vital statistics, in promoting the adoption of uniform vital statistic laws in the various states, and that the secretary be instructed to furnish a copy of these resolutions to the above-mentioned gentlemen.

JOINT CONFERENCE ON MEDICAL PRACTICE ACTS

Medical Practice Acts and the Public

Hon. Edward J. Brundage, Corporation Counsel, City of Chicago: Notwithstanding the vastly greater importance of the public health, all requirements for the practice of medicine have been left by the people to the physicians themselves. While watchful over the possession of things material, the people have been careless in their dealings with the most precious of all assets—good health. If unfit men are practicing medicine in this day, the fault is not with the profession, but with the public that permits quack-producing conditions to exist. There has been a great advance in the last decade in the standard for the practicing of medicine, and physicians are entitled to the credit for raising the standard. The public, through ignorance or lack of understanding, has contributed little toward helping physicians in this work. The state of the public health is dependent on the progressiveness of the medical profession, but the profession is not responsible if the public is lax. Some of the people have become aware of this situation, but the vast majority are still unable to discriminate between physicians properly trained and those untrained. The title of doctor is the most abused of all. In its common use it signifies nothing as a title of learning or distinction. Doctors are of as many varieties as the product of a pickle factory. The thing essential for the protection of the public is some way to discriminate between men bearing the title. In my judgment a man of training, high education and character, ought to possess a title distinguishing him from the man who treats the diseases of animals or practices chiropody. But one course appears to the layman to protect the public against such incompetency, and that is to raise the standard of admission to medical colleges by requiring a preliminary degree in arts or sciences as a prerequisite. Even then, after graduation, no license should be granted to practice medicine or surgery until actual experience in a hospital or similar work has been obtained, for a sufficient period to demonstrate ability.

The best evidence that the public is becoming aware of the importance of the physician to the welfare of the community is the growing demand for the creation of a national department of health. Problems in matters of health are constantly being created with the rapid growth of urban life. Medical science is taxed to its greatest capacity to obviate the danger caused by the massing of people in restricted areas. No branch of science has progressed so rapidly, no profession contains more thinkers, willing to devote their lives to the betterment of mankind. The public is learning more and more to depend on physicians, and I am sure the progressive men of the medical profession will find increasing support from the public at large.

Attitude of the Judiciary in Enforcement of Medical Practice Acts

Judge Jesse A. Baldwin, Appellate Court, Chicago: The medical practice acts in the various states have been vigorously contested on the ground of alleged unconstitutionality. A proper consideration of the basis on which such legislation rests readily discovers satisfactory reasons why the courts, in more than thirty of the states where the legislation was directly attacked, have distinctly sustained the constitutionality of such legislation. With the medical practice acts varying, as they do, in the several states, and with supreme courts, and in many instances appellate courts, in each of the states, it is not surprising that there should be a lack of absolute uniformity either in the legislation or in the decisions of the courts under it. It is difficult to draw any conclusion as to the attitude of the judiciary in the enforcement of medical practice acts from the decisions, and yet examination makes it safe to say that so far as they are criminal statutes, enforcible by fine and imprisonment, the courts are required by the accepted canons of construction to construe them strictly, but examination also shows that both the judiciary and the medical fraternity are applying a progressive science.

While possibly the courts are even more conservative, and more subservient to precedent than the medical profession, no one, after a careful review of the situation, can deny that even the courts are affected by new and progressive views and constructions which are, by changed conditions and necessities, made applicable to the case under consideration. The statutory regulations in regard to the practice acts must be adopted in good faith, must be reasonable, must operate equally on all alike, must prescribe qualifications reasonably possible of attainment by study and character, and fairly intended to protect the public against fraud and imposition. If these requirements are met, the acts will be sustained by the courts, even though the conditions are rigorous, and though sometimes the provisions are not such as the court would itself deem the wisest.

"*Let me urge you to move forward unitedly, and secure in the interests of suffering humanity the strongest and best legislation possible; continue in your efforts to compel higher standards in your profession, subordinating selfish interests to the public good, and be assured that the attitude of the judiciary in the enforcement of legislation enacted under such conditions and to embody such purposes will be cordially sympathetic.*"

What Should be the Attitude of the State Toward the Practice of Medicine

Dr. M. L. Harris, Chicago: The only justifiable pretext for a medical practice act is that it shall protect the people against ignorance and incompetence on the part of those who treat the sick. It was thought that this might be accomplished by prohibiting anyone from practicing medicine who had not been licensed so to do, and in not licensing anyone who had not proved himself qualified. A law carefully drawn up on these lines and strictly enforced would undoubtedly restrict the practice of medicine to those qualified. But none of the acts so far passed adhere strictly to this plan nor are any of those which closely approximate it strictly enforced. The state should not attempt to restrict the practice of medicine to a particular class, but should designate those who are competent so that the public may be able to distinguish between the competent and incompetent. Joined to this duty of guidance is the equally important duty of protection. None but qualified physicians should be eligible to any medical position in the public health service, or in any public or charitable institution under the control of the state or any of its municipalities. As all contagious diseases are a menace to the public, and as most of them should be reported to the proper health officers, no unqualified person should be permitted to treat or to assume the medical care of people suffering from these diseases. All parents, guardians and institutions having minors under their care or control should be obliged to furnish them with qualified medical attention in case they are sick or injured and require it. No death certificate should be accepted by the authorities unless signed by a qualified physician. In this manner the state will be able to carry out its duty of protection.

The restrictive or licensing plan of regulating the practice of medicine is fundamentally wrong in principle in that it makes the state dictatorial in a matter of personal rights which is best left to the thinking individual.

Regulation of the Practice of Medicine for the Public Good

Mr. Charles R. Henderson, Professor of Sociology, University of Chicago: Studies and experience disclose the necessity of training in purely scientific investigation. Every advance movement in public hygiene must start from a new laboratory revelation, as the control of diphtheria, typhoid, tuberculosis, summer diseases of infants. Not all, not even a majority of physicians, can be pioneers, but every one should have the fundamental discipline which will make him intelligent and sympathetic toward the investigators. The educated physician is needed to save the nation from quackery which fattens on popular ignorance and inherited superstition. The "patent-medicine" vendors and the faith-healers thrive because science is not a common heritage. The alcoholic superstition owes its survival partly to the want of unanimity among doctors. Free competition in each calling has limits of usefulness. A physician's "trust" is desirable on certain conditions: it must admit all who are competent; it must use fair tests to exclude all others; its charges must not be prohibitive to the poor. Some affect to fear that examinations will snuff out some spark of genius; but the criticism of scholars is a guarantee that no valuable idea will be lost. Indeed, the higher the standard of state examination, the more certain it becomes that every possible hypothesis will be adequately tested by men who try their experiments cautiously on animals before they take too great risks with human patients.

The Administration of Medical Practice Laws

DR. A. B. BROWN, Secretary Louisiana State Board of Medical Examiners: In order for the Board of Medical Examiners to administer usefully the functions that should belong to such a board, it is essential that there should be legislative authority broad enough to permit the board to cover the entire field of regulation of practitioners of medicine. Such a statute must not be too strict in limiting the power of such board. It is humanly impossible for the author of a statute of this nature to foresee all the possible changes that may occur in connection with the development of medical science. The definition of the practice of medicine must be comprehensive. It must enable the board to reach every person who professes to cure disease, or to remedy defects in human beings, or to relieve physical pain or to rectify mental aberration. As a prerequisite to the right to take examinations, the statute should require the presentation to the board of examiners of a diploma, or equivalent certificate showing that the candidate had completed, to the satisfaction of the medical college issuing it, his course in said college; said diploma or equivalent certificate must be issued by a college the requirements of which are satisfactory to the board. The standing of each college must be left to the judgment of the board of examiners. There can be no other judge of the collegiate standing than the board. The legal procedure by which the law is to be enforced should be such as to render the board independent of any local influences that might attempt to obstruct the provisions of the board.

Financing of State Board Work

DR. HERBERT HARLAN, President, Maryland State Board of Medical Examiners, Baltimore: The objection to the financing of state boards by the state, is the difficulty in arranging for a liberal expense account under the control of the board. For example, would the average controller pass the voucher for *per diem* and traveling expenses of a representative of a a board to attend such a meeting as this one? Again, the state law officers would surely be expected to act as counsel in defending suits and pushing prosecutions. Many state's attorneys have shown themselves to be, if not hostile, at least very indifferent in regard to enforcing medical practice acts. In Maryland we had great difficulty on this point even though we have our own attorney to aid us. It is my opinion that the best results would come from leaving the distribution of the funds entirely with the boards. In certain states, where the amount is large, larger than is needed for all expenses and for reasonable compensation of the secretary and members, as the money all comes from the physicians, there could be no serious objection to having the surplus turned over to the uses of the state medical society.

CONFERENCE OF THE NATIONAL LEGISLATIVE COUNCIL

The chairman, Dr. H. B. Favill, appointed the following committee on resolutions: Dr. E. J. McKnight, chairman, Hartford, Conn.; Dr. A. B. Brown, New Orleans; Dr. R. M. Funkhauser, St. Louis; Dr. Charles F. Whithington, Boston; and Dr. Frederick R. Green, Chicago, secretary of the Council on Health and Public Instruction, ex officio.

DR. F. R. GREEN, Chicago, presented his report, after which there was a roll-call by states and presentation of reports from state representatives. There were also reports from interim committees, Carroll memorial, medical expert testimony and optometry.

Report of Committee on Optometry

DR. JOHN C. BOSSIDY, Chairman, Boston: Twenty-four states had legalized optometry by the end of 1909; or, as opticians claim, had recognized it as a profession. In 1910 physicians vigorously fought the further extension of this pernicious measure, and the opticians were beaten in every state where they made their effort. The committee finds apathy on this subject in the medical ranks. The fight in the past has been by a few medical men, and this state of affairs should be remedied. Columbia University, of New York, was persuaded during the last year to establish a course in optometry. The university prescribed a minimum of twelve students before starting the course. The result of the establishment of this course has been that Columbia University has been quoted in many states as the chief argument for the establishment of further optometry laws; and yet, with all this effort, there were on the first of February of this year, but eleven students taking this course. The committee is impressed with the great harm that can be done to the public through unwise legislation, and its members hope that every medical man present at this conference will see this subject in all its present and future dangers.

Educational Work in Vital Statistics

DR. CRESSY L. WILBUR, Chief Statistician, Bureau of the Federal Census, Washington, D. C.: One of the chief assets of the Bureau of the Census in its work of endeavoring to promote the better registration of vital statistics in the United States is the continued earnest cooperation of the organized medical profession. Nothing could be done if the physicians of the United States were opposed to the enactment and enforcement of effective registration laws, and practically all that has been done to secure such legislation has been through the active efforts of the medical profession. The registration service in the United States is too often treated as merely clerical or the mechanical part of public health organization and entrusted to utterly incompetent hands. The result may be exceedingly disastrous when the health officer undertakes to test his work by the use of vital statistics, and in general it may be said that all sanitary workers in this country are hampered by the lack of uniformity and thoroughness in statistical publications; hence the desirability of building up, with its roots in the broad scheme of medical education, a body of trained practical workers in vital statistics and appreciative students and users of their results. This object is nearer to accomplishment than ever before, but it will take many years of earnest cooperative effort on the part of these councils of education and legislation, with the full support of the entire profession before we shall bring this neglected subject up to the full measure of its usefulness.

REPORT OF COMMITTEE ON RESOLUTIONS

The Committee on Resolutions presented the following report, which was adopted:

WHEREAS, The Committee on Carroll Memorial has completed its work in a highly satisfactory manner to all concerned; therefore, be it

Resolved, That the final report of the committee be accepted and the committee discharged; and be it further

Resolved, That the committee recommends that the cordial thanks of the conference be extended to Major Ireland and his committee for the efficient manner in which they have accomplished their work

Resolved, That the thanks of the conference be extended to Drs. Halsey, Gay and Bristow for their individual efforts in the consideration of medical expert testimony, and that this committee be discharged; and, be it further

Resolved, That the Council on Health and Public Instruction be requested to establish a standing committee to give this matter thorough consideration and, if possible, to confer with a committee of the American Bar Association.

Resolved, That the Seventh Annual Conference of the American Medical Association on Medical Education and Medical Legislation deplores the action of Columbia University, of New York, in establishing a course of study in optometry, for the reason that opticians have never succeeded in founding an official school of optics or optometry, but have relied on the recognition or legalization of the word optometry to make them a profession, and for the further reason that the existence of such a course at Columbia University has this year been used in many states as the chief argument for the further enactment of optometry laws, which are designed to permit opticians to practice medicine in a limited degree; and, be it further

Resolved, That a copy of these resolutions be transmitted by the secretary of the conference to the president of Columbia University of New York.

Resolved, That this conference reaffirms its endorsement of the model bill on vital statistics and expresses its appreciation of the interest shown by Hon. E. D. Durand, director of the census, and by Dr. Cressy L. Wilbur, chief of the division of vital statistics, in promoting the adoption of uniform vital statistic laws in the various states, and that the secretary be instructed to furnish a copy of these resolutions to the above-mentioned gentlemen.

Medical Economics

THIS DEPARTMENT EMBODIES THE SUBJECTS OF ORGANIZATION, POSTGRADUATE WORK, CONTRACT PRACTICE, INSURANCE FEES, LEGISLATION, ETC.

THE SECRET COMMISSION EVIL

The following editorial appeared in *Colorado Medicine*, February, 1911:

> "EVERY MAN WHO DOES GOOD WORK SHOULD BE PAID FOR WHAT HE DOES, AND NO MAN SHOULD BE PAID FOR WHAT HE DOES NOT DO."

1. A surgeon who lets it be understood that he will give to every doctor sending him a case, a certain proportion of the fee, whether he earns it or not—say half, as is frequently done—really makes every one who agrees to this his hired agent, just as much as if he sent him out to canvass the incoming railroad trains with the promise of a fat commission for every patient he might steer in.

These agents are sometimes beginners in practice or else more or less unsuccessful and unscrupulous practitioners. They soon discover that they can make more money and make it easier by furnishing cases on commission than they can through legitimate practice, and their hunt for subjects for operation becomes a frantic one. With a poorly paying practice on the one hand and a rich bait of 50 per cent. of the fee dangling within easy reach on the other, they soon begin to strain a point and urge operations where operations are unnecessary. It becomes easy to say: "If you are not operated on you will die." Under the circumstances excuses for this questionable conduct are easily found.

Now, the surgeon who employs these agents is a more or less unscrupulous man, who is wildly grasping for work and does not care how he gets it. He is not willing to earn it by proving to others that he can do things well, thus establishing a legitimate reputation—the recognized and approved method—but he is anxious to buy his work and let the proof of ability come afterward, if it ever does come.

It may be said that such a man may soon become an expert operator, owing to the amount of work which he will do. True: but an expert operator does not constitute a good surgeon—this requires, in addition, judgment, learning, conscience, and an undeviating purpose to do that which is best in every respect for the patient, irrespective of fees and operative statistics. In this sense, he who buys his cases can seldom become a good surgeon.

When an agent sends a case to such a commission-paying employer, the necessity for an operation has often been exaggerated so as to make sure of bagging the game. Hence, in order to protect the interests of his agent, as well as the interests of his pocket, the surgeon *must* operate; but it can readily be conceived that his already elastic conscience is usually equal to the emergency; and I venture to say that few such cases are ever turned down, even when an operation is not really called for.

2. Hence, the commission business leads to indiscriminate, reckless and useless operating; and in these days, when the tendency in this direction is already too great, owing to the comparative ease with which many operations can be done, this is unfortunate, to say the least.

3. Individual ability in different lines of work should be encouraged and not hampered. In every community there are surgeons who are noted for certain things—one is particularly skilful in hysterectomy, another in operating on the brain, a third in the surgery of the appendix, a fourth in stomach and gall-bladder work. The general practitioner is supposed to find out in the course of time who these men are, and his patients have a right to expect that he will use this knowledge for their benefit. But how can a fine, *or* even a coarse discrimination be exercised with 50 *per cent. of the fee* obscuring the vision, and with [illegible] out and take it? The doctor's employer, [illegible] surgeon, inevitably gets the case, whether he is the best man to handle it *or* not.

Suppose your wife were very sick and required the services of a surgeon, and you trusted your family physician to pick out the one best suited to operate on this particular case; and you found out afterward that the surgeon had really been selected not because of fitness, but because he paid your doctor half the fee for selecting him. How would you feel about this? Would you not feel that you had been buncoed? Would you not call it an unjustifiable traffic in human misfortune? Would you not feel like shooting your family physician, especially if disaster resulted to your wife?

4. Publicity is what is needed: If but two doctors resided in a small town and one was known to be a "commission-doctor," while the other carried on a legitimate business of his own, being in the employ of no one and choosing his surgeons according to their merits alone—if this state of affairs existed, other things being equal, how long would it take the populace to make a selection between these two men?

And this suggests the easiest, best and quickest manner o doing away with the commission evil—publicity. Such things flourish in darkness. Turn on the light and they run for cover Is there any doubt that if the public knew a surgeon obtained his work by paying commissions rather than by proving his skill it would express its disapproval by avoiding him?

5. Every man should be paid for what he does, and no man should be paid for what he does not do:

Simply referring a case to a surgeon without further action should usually mean a consultation fee only, which the patient will generally pay without question. It is true, however, that in surgical cases the responsibility is often increased by advising operation: but if the case is one which should go to the surgeon, is not the responsibility even greater if he is not so advised? In fact, the responsibility cannot be escaped either way. It would be right, however, for medical men to demand a larger fee for the added responsibility and trouble accompanying the diagnosis of many surgical cases, the selection of a surgeon, and other matters incidental to the necessary arrangements for an operation. When this matter is presented in a proper light to the public it is always quick to see its justice.

When a case is sent to a surgeon, especially to a strange surgeon in a strange city, the patient often desires his physician to accompany him. Even when this is not actually necessary it contributes a feeling of security and backing which would otherwise be absent. In addition, most individuals wish their physician to be present at an operation, and it gives them confidence to know that he is there and watching over their interests. They also want him to see them during their convalescence, to cheer them up and to make such suggestions as his knowledge of *their peculiarities* may prompt.

There can be no question that these attentions should be paid for according to their value; but this is not yet sufficiently recognized. Physicians too often give their time and skill and receive *no pay* in return. Undoubtedly, the proper method would be for the *patient to meet these obligations directly* At present, however, he often does not see it in this light, and in order to educate the people up to this point (6) it is permissible for the surgeon and the physician to present a joint bill—for services rendered by Dr. A. and Dr. B. This can be *itemized* if desired, or at least it should be if the patient request it. Understand, what makes such a joint bill legitimate is that it is clearly indicated that it is for services rendered by *both* the attendants, and not by the surgeon alone In this way it not only assists the physician in collecting his just dues, but also helps to educate the public to understand that the physician's time and services in connection with an operation are worth something—a point well worth driving home at every opportunity, because services for which nothing is charged are usually estimated as being worth nothing.

The other day a Denver surgeon remarked: "It is nobody's business what I do with a fee, as long as I do not overcharge—if I want to give half of it away, that is my affair, and does not concern the patient or anyone else." But it does concern some one else. It concerns the patient, the public and the *whole medical profession.*

If we wish to retain the confidence of the public, and our own honesty and self-esteem, no transaction should be entered into that we cannot openly lay before the patient and his friends. This is a precept which we cannot afford to neglect The tendency is already too great to distrust the actions and motives of doctors, and we should do all in our power to combat it rather than to encourage it. We should in every way endeavor to convince people that we are honest men with right motives who are trying, within our limitations, to cure the sick without taking undue advantage of them. This is really what separates us from the charlatan and the quack. It is the standard raised by our forefathers, and we should endeavor to maintain it.

7. When an agent receives part of a fee without earning it somebody suffers—either the surgeon gets too little or the patient pays too much. In the former instance the rights and dignities of the profession are trampled on, and in the latter the individual is buncoed.

For the surgeon's agent to receive from the patient something for nothing without the patient's knowledge, is as culpable as if he engaged in a get-rich-quick scheme, or robbed a bank or held up a citizen on the highway. Because surgeons are popularly believed to make more money than the general practitioner, which in the long run is questionable, is no reason why the latter should graft either on the surgeon or on the public. If there is a real grievance it should be rectified in some more legitimate manner, in accord with the high ideals and moral responsibilities which physicians are supposed to possess—for instance, by educating the public to understand that with the growth of surgery increased responsibilities and duties have been thrust on the general practitioner, which should receive increased remuneration.

It goes without saying that every surgeon will be glad to assist in such a campaign of education so far as lies within his power. For instance, a few words to the patient in explanation of the situation are usually sufficient to bring about a proper understanding of the value of the services rendered by the physician before the operation, during or after it; assuming, of course, that the physician is not a grafter and desirous of obtaining remuneration for something he does not do. It is usually easy enough to convince a patient that a good diagnosis, involving the responsibilities and trouble of an operation, is worth more than ordinary medical services, and should be paid for accordingly, but this can never be done by the medical man pretending to work for nothing and then getting half the fee from the surgeon.

8. Buying cases is worse in some ways than advertising in the daily press, because the public has no way of protecting itself against this form of graft. All members of the profession recognize that advertising in the newspapers or on bill-boards is a serious breach of ethics. This is one thing on which we fully agree and are extremely "touchy." The reason for this is not so much because it lowers our dignity and cheapens us, although this is of importance, but because advertising enables men to make false and wonderful claims to deceive the public, the extent of which is limited only by their ability to write and pay for advertisements. From time immemorial it has been recognized that the only decent and honorable course for the doctor to pursue is to let his work speak for itself, and not cry his accomplishments from the house-tops, this being left to the quacks and to the charlatans. If we acknowledge this to be true, how do we reconcile with it the actions of the commission-paying surgeon? Instead of letting his work speak for itself, he pays for his cases—he does not make his reputation, he buys it like any other charlatan. He introduces into the profession a form of advertising much more pernicious than that which employs the newspapers, because against its secret practice the public cannot defend itself. People may be too intelligent to be misled by the allurements of an ordinary advertisement; but when they are steered against a commission-paying surgeon by his paid agent they are helpless, because the game of graft and bunco is a hidden game and not an open one, like that of the ordinary quack.

POSTGRADUATE COURSE FOR COUNTY SOCIETIES

DR. JOHN H. BLACKBURN, DIRECTOR
BOWLING GREEN, KENTUCKY

[The Director will be glad to furnish further information and literature to any county society desiring to take up the course.]

Eighth Month—Second Weekly Meeting

TUMORS OF THE UTERUS

FIBROMYOMATA: Histologic varieties, number, size, rate of growth. Clinical varieties; interstitial, subperitoneal, submucous and intraligamentous. Secondary changes: Atrophy, calcification, fatty degeneration, infection, edema, necrobiosis, cystic degeneration, malignancy.

DIAGNOSIS: History, symptoms, physical examination.
1. Interstitial, pelvic and abdominal in situation.
2. Subperitoneal, pelvic and abdominal in situation.
3. Submucous fibroma. Uterine polypi.
4. Intraligamentous, between folds of broad ligament, anterior and posterior tumors.

CHORIOEPITHELIOMA, DECIDUOMA MALIGNUM

ORIGIN: Fetal or maternal. Location. Microscopic diagnosis. Metastasis.

SYMPTOMS: History, hemorrhage, discharge, pain, anemia, cachexia, etc. Physical examination. Symptoms of metastasis. Differentiate from carcinoma and sarcoma, incomplete abortion, submucous fibroid.

CANCER OF UTERUS: (a) Of the body, (b) of the cervix. Diagnosis, history, symptoms, physical signs, microscopic examination.

SARCOMA OF THE UTERUS: 1. Fibrosarcoma, affecting primarily the parenchyma. 2. Diffuse sarcoma, affecting primarily the endometrium. Diagnosis of each type.

Medical Education and State Boards of Registration

COMING EXAMINATIONS

CONNECTICUT: Regular, City Hall, New Haven, March 14-15. Sec., Dr. Charles A. Tuttle; Homeopathic, Grace Hospital, New Haven, March 11. Sec., Dr. Edwin C. M. Hall, 82 Grand Ave.; Eclectic, Hotel Garde, New Haven, March 14. Sec., Dr. T. S. Hodge, 19 Main St., Torrington.

MAINE: Portland, March 14-15. Sec., Dr. F. W. Searle, 806 Congress St., Portland.

MASSACHUSETTS: State House, Boston, March 14-16. Sec., Dr. Edwin B. Harvey, Room 159, State House.

Indiana January Report

Dr. W. T. Gott, secretary of the Indiana Board of Medical Registration and Examination, reports the written examination held at Indianapolis, Jan. 10-12, 1911. The number of subjects examined in was 16; total number of questions asked, 100; percentage required to pass, 75. The total number of candidates examined was 17, of whom 16 passed and 1 failed. Seven reciprocal licenses have been granted since Jan. 1, 1911. The following colleges were represented: .

PASSED

College	Year Grad.	Per Cent.
Howard University, Washington, D. C.	(1910)	86.7

Book Notices

Practical Bacteriology. Blood Work and Animal Parasitology. Including Bacteriologic Keys, Zoölogic Tables and Explanatory Clinical Notes. By E. R. Stitt, M.D., Surgeon, U. S. Navy. Second Edition. Cloth. Price, $1.50 net. Pp. 345, with 91 illustrations. Philadelphia: P. Blakiston's Son & Co,, 1910.

In the second edition of this book the original arrangement has been adhered to, but the matter has been thoroughly revised. Chapters on immunity, anaphylaxis and poisonous snakes have been added, and the matter on the important subject of animal parasites has been rewritten, as has also the section on the bacteriology and parasitology of the body fluids. Other additions are, an outline of methods for the chemical examination of urine and gastric contents, and for the determination of nitrogen elimination. The author has avoided theoretical consideration, and does not hesitate to say plainly what is and what is not important in laboratory diagnosis. This is an advantage, when spoken with the authority of knowledge and experience. The book is well illustrated. Methods and procedures are concisely yet clearly given. The usefulness of the index, however, and consequently of the book as a work of reference, is impaired by the fact that the parasites are indexed solely under the name which the author has adopted, even though that may be less familiar than another name. Thus, *Lamblia intestinalis*, *Acanthia lectularia* and *Necator americanus* are indexed under those names alone; one looks in vain for *Cercomonas*, *Cimex* and *Uncinaria*. Unfortunately, moreover, the index is not complete, even as to names used by the author.

The Hygiene of Infancy and Childhood and the Underlying Factors of Disease. By A. Dingwall Fordyce, M.D., Extra Physician, Royal Hospital for Sick Children, Edinburgh. Cloth. Price, $2 50 net. Pp. 289. New York: William Wood & Co., 1910.

In this book the author has attempted to "correlate the primary scientific facts of medicine as they apply especially to pediatrics," in order to assist the pediatrist in keeping abreast of the scientific advances associated with his own clinical work. Food, heredity, environment, bacterial infections and the different age periods with their characteristics and susceptibilities to disease and their developmental peculiarities, are discussed.

Fever-Nursing. Designed for the use of Professional and other Nurses, and especially as a Text-Book for Nurses in Training. By J. C. Wilson, M.D., Author of "A Treatise on the Continued Fevers." Cloth. Price, $1 net. Pp. 248. Philadelphia: J. B. Lippincott & Co., 1910.

The text of this book, which originally embodied the substance of Dr. Wilson's lectures before the nurses' class at the Philadelphia Hospital, has gone through revisions until this, the fifth edition, contains only the essentials of nursing in fevers according to present ideas. The demand for a new edition gives evidence that it is meeting its purpose.

The Prescribing of Spectacles. By Archibald Stanley Percival, M.B., Senior Surgeon Northumberland and Durham Eye Infirmary. Cloth. Price, $2 net. Pp. 159, with 24 illustrations. New York: William Wood & Co., 1910.

The author presents the subject of refraction in a practical manner, enabling one to quickly grasp the essentials in determining the errors of refraction and of ocular muscle balance. The use of the various instruments of precision is well treated, and some space devoted to the various types of lenses. A large part of the book is given to the mathematical problems connected with this subject.

Notes on Dental Metallurgy. For the Use of Dental Students and Practitioners. By W. Bruce Hepburn, L.D.S. (Glasgow), Lecturer on Dental Metallurgy and Visiting Dental Surgeon in the Glasgow (Incorporated) Dental Hospital and School. Cloth. Price, $2 net. Pp. 213. New York: William Wood & Co., 1911.

This work is a most complete summary of dental metallurgy. It is written on a short, concise plan, and the subjects can be quickly and easily referred to by the student. Those making a specialty of this line of work should have this book within reach for reference.

Studies in Invalid Occupation. A Manual for Nurses and Attendants. By Susan E. Tracy. Cloth. Price, $1.50 net. Pp. 175, with illustrations. Boston: Whitcomb & Barrows, 1910.

Although this book is not directly medical, it is of interest to physicians, and to all who have to do with invalids. Practically every sort of work that may be employed to pass the tedious time of persons crippled or otherwise shut-in has been explained and illustrated here.

Medicolegal

Insufficient Evidence of Malpractice and Erroneous Rulings

The First Appellate Division of the Supreme Court of New York reverses, in Brown vs. Goffe (125 N. Y. S. 458), a judgment for malpractice, and orders a new trial. It deems it sufficient to say that the principal operation performed by the defendant involved the removal of certain of the plaintiff's organs which had become diseased. Later in the same day a condition arose which required a second minor operation, mainly for the purpose of drainage, and some time later a second incision was made for the same purpose. Still later, after the plaintiff had sufficiently regained her strength, a fourth operation was performed, consisting of opening one of the incisions already made and securing so far as possible some of the spots found to have been weakened by the infection found on the occasion of the first operation.

The burden of the complaint was that the defendant, while possessing the requisite skill and learning, did not use reasonable care in the exercise of his skill and the application of his knowledge. But there was no evidence in the case from any qualified witness to the effect that any one of the operations performed by the defendant was improper, or was carelessly, negligently, or unskilfully executed. Furthermore, the charge of negligence and carelessness in the aftercare of the patient rested entirely on the evidence of the plaintiff herself, a young woman about 25 years of age who had been employed as a waitress in a restaurant, contradicted in the main not only by the defendant, but also by his assistants and the house surgeons of the hospital. It was insisted throughout the trial and on the appeal that the defendant had compelled the plaintiff to lie for days at a time with unchanged bandages and dressings. This insistence had no better foundation than the plaintiff's inadmissible evidence that one of the hospital staff had told her that the defendant had given orders that the bandages should not be changed. No legal evidence of such an order was given. But counsel quoted a sentence from the defendant's evidence that "I never ordered the bandages removed," but carefully refrained from quoting the very next sentence, that "the bandages were taken off every day after they were soiled." It is well settled that the burden of establishing affirmatively either want of skill or negligence in the care and attention of a patient must be assumed by him.

A very important inquiry in a case like this is whether or not the defendant did that which his best judgment dictated. One of the obligations resting on a surgeon or physician is to use his best judgment in exercising his skill and applying his knowledge, and when his acts are challenged it must necessarily be open to him to show that they accorded with his judgment as to what should have been done. So the defendant was prevented from showing precisely that which it was incumbent on him to show, when this question was excluded: "Now, in performing this operation did it, in your judgment, become necessary to separate the tissues in either way from the sac in which the pus was found?"

The necessities of the case required that the defendant should leave, in a large measure, to the hospital staff the care of the patient after the operations, which it was shown was the usual and proper practice in hospital cases, and it was error not to allow him to answer the perfectly proper question as to what instructions he left with the hospital physicians or nurses as to care of the patient.

Practice of Medicine by "Suggestive Therapeutics"

The Fourth Appellate Division of the Supreme Court of New York in People vs. Mulford (125 N. Y. S. 680) affirms a conviction of the defendant of practicing medicine without having a license and being registered as required by Chapter 344 of the Laws of New York of 1907, which declares that "A person practices medicine within the meaning of this act . . . who holds himself out as being able to diagnose, treat, operate or prescribe for any human disease, pain, injury, deformity or physical condition, and who shall either offer or undertake by any means or method to diagnose, treat, operate or prescribe for any human disease, pain, injury, deformity or physical condition."

It appeared from the evidence, without contradiction, that the defendant had an office, where he received patients, and treated them for physical ailments, and received compensation therefor; that he gave no medicine, and prescribed none; that he performed no surgical operations, and used no surgical instruments; that his entire treatment consisted of the laying on of hands, and manipulation, breathing and rubbing his hands together; and that his treatment was beneficial to his patients. The sign in front of his office indicated that his treatment was known and designated as "suggestive therapeutics." On the evidence he was practicing medicine, the court holds, as defined by the above statute, and was guilty of a misdemeanor thereunder.

The only contention of the defendant was that the statute is a violation of the state and United States constitutions, but it does not seem to the court to require any extended discussion to show that the legislature had the right to enact the provisions of this law, and that it does not violate the provisions of the constitutions.

It was said that the defendant could do no harm, if he did no good, and that he should therefore have been permitted to practice his calling without interference, and that this law, which brought him within the definition of one who practiced medicine, and was therefore prohibited from doing so without a license and being registered, deprived him of a legal right to carry on a proper business, and was a violation of the provisions of the constitutions. But a patient may often suffer as well from a failure to prescribe proper remedies, or afford surgical relief promptly, as from making improper prescriptions, or performing unskilful operations. A physician who holds himself out to treat patients for physical ills should know whether to do anything, and what to do, to relieve his patient; otherwise, he should not be permitted to practice, and impose on the unfortunate sufferers who, like the poor, are always with us, and many of whom need the protection of the state against quacks in and out of the profession of medicine. "I [Justice Williams wrote the opinion] have no sympathy with this class of practitioners, who seek to remain outside of the control of the state, for the welfare of the people."

School Boards May Employ Suitable Persons to Ascertain Physical Condition of Pupils

The Supreme Court of Minnesota holds, in State ex rel. Stoltenberg vs. Brown, City Comptroller (128 N. W. R. 294), that a school board may employ a suitable person to ascertain the physical condition of the pupils in attendance on the public schools of the district.

The court says that the education of a child means much more than merely communicating to it the contents of textbooks. But, even if the term were to be so limited, some discretion must be used by the teacher in determining the amount of study each child is capable of. The physical and mental powers of the individual are so interdependent that no system of education, although designed solely to develop mentality, would be complete which ignored bodily health. And this is peculiarly true of children, whose immaturity renders their mental efforts largely dependent on physical condition. It seems that the school authorities and teachers coming directly in contact with the children should have an accurate knowledge of each child's physical condition, for the benefit of the individual child, for the protection of the other children with reference to communicable diseases and conditions, and to permit an intelligent grading of the pupils.

In this case the board of education of Minneapolis, pursuant to a previously adopted resolution recommending the employment of a suitable graduate nurse for one month to make an inspection of the physical condition of the pupils of certain-named schools, appointed the relator to make such inspection at a salary of $60 for the month's services. She performed those services, a warrant for her pay was drawn and signed by the president and secretary of the board, but the city comptroller refused to countersign the warrant. The above considerations and many others not deemed by the court necessary to mention leads it to the conclusion that the comptroller was properly directed by mandamus to countersign the warrant.

4. Nature of Virus of Yellow Fever, Dengue and Pappataci.—In reviewing the work which has been done on the nature of the virus of yellow fever, dengue and pappataci fever, Craig says that one is impressed with the similarity existing between them, a similarity which points to the close relationship of the causative organism. Clinically, there is considerable resemblance, all three diseases having a sudden onset, running a comparatively rapid course, and terminating by crisis rather than by lysis. In point of severity, pappataci fever is the mildest, yellow fever the most severe, while dengue occupies the position between the two. In all three the cause is present in the blood, but only during certain periods; in yellow fever during the first three days of the disease; in pappataci fever during the first day; and in dengue, so far as is known, during the third and fourth days of the attack. In all, the injection of filtered or unfiltered blood produces the disease. All three of the fevers are transmitted by an insect; in two, yellow fever and dengue, by a mosquito, and in pappataci fever by a biting fly. In yellow fever and pappataci fever the causative agent undergoes a cycle of development within the transmitting insect, while in dengue this point is still undetermined. In yellow fever the mosquito does not become infective until twelve days after it has bitten the infected individual, while in pappataci fever the fly does not become infective for from seven to ten days. In all three diseases the causative agent is ultramicroscopic in size, as is passes through the best filters that can be obtained, and because the most careful examinations of the blood both microscopically and culturally have failed to show any parasite. In addition, there is conclusive evidence that these diseases are not contagious. The careful consideration of all of these facts impresses Craig with the belief that yellow fever, dengue, and pappataci fever, as well as other diseases due to a filterable virus, are caused by parasites which differ markedly from any with which we are acquainted. The evidence goes to show that they differ from one another in virulence, thus producing the variations in the clinical picture of the three diseases, just as in malarial infection we have different species of plasmodia which produce mild or severe attacks. In many respects these fevers resemble those due to the malarial plasmodia. Like the malarial fevers, they are transmitted by insects, but may be produced by the injection of blood from an infected individual; while there is almost as much difference in the severity of the fever due to the benign tertian plasmodium and the often fatal infection produced by the estivo-autumnal plasmodia, as there is between yellow fever and severe dengue. The discovery of the actual organisms concerned in the production of these fevers is apparently impossible until we can perfect the microscope or discover some method of staining or cultivating them, but Craig believes that, in time, it will be proved that these fevers are due to closely related species belonging to the same genus, and that in all probability they will be found to belong to that great class of organisms which are daily becoming of more vital interest to the physician, the protozoa.

15. Vital Statistics in Illinois.—The history of the vital statistics movement in this country is discussed fully by Webster. His concluding remarks, based, in the main, on the Illinois situation, although applicable to other states occupying the same position as Illinois in this matter, are, in part, as follows:

It is the duty of the State of Illinois to see to it that at least the three principal events in the life of each of its citizens be made a matter of public record. These three principal events are birth, marriage and death. Illinois has spent $40,000,000 on a sanitary canal, largely for the purpose of improving the water supply of some of her cities and chiefly for the purpose of diminishing deaths from typhoid. To what extent has the typhoid death-rate of the state as a whole been affected? Nobody knows. Owing to the lack of any adequate system of sanitary bookkeeping, we don't know the actual annual death-rate in the state, from typhoid, or any other disease, either before the canal was opened, or afterward. What would you think of the business sagacity of a corporation that would spend $40,000,000 on some improvement and then fail to keep a set of books that would enable it to know whether it was a paying investment or not? For several years the Illinois State Board of Health has been engaged in a state-wide antituberculosis crusade. And with what result? Nobody knows. We do not know the exact death-rate from this disease and consequently are not in a position to estimate correctly the value of any or of all the methods instituted for its suppression. The Illinois State Geologic Survey and the Illinois State Water Survey have done splendid service in showing the need of a better water-supply and how to obtain it. What effect has it had on the typhoid or other mortality? Nobody knows. In Illinois, the birth or the death of a blooded horse or a Jersey bull is at once recorded in a herd-book, but the people of southern Illinois, through the voice of their chosen representatives, have gone on record as saying that it is too much trouble to obtain legal permission to bury their dead or to make a legal record of the event and, consequently, in this state, outside of cities having ordinances with a compulsory burial-permit feature, a human being may be placed underground without the slightest legal note or record. What a disgrace to our state that we should be found holding open the door for graveyard insurance. When a human being can pass, or be sent, from this world to the next, without a single formality, inquiry into or record of the cause of the death, and the body buried like a dog, it is time we enacted and enforced a suitable law, if for no other reason than as a deterrent of crime. Good laws are the expression of an enlightened public sentiment enacted for the protection of society as a whole, and not for any class, and another failure to enact a satisfactory birth and death law in Illinois will be greatly to the discredit of the intelligence and public spirit of the people of the state. For sanitary, legal, social, economic reasons, Illinois should prepare and enact, and then enforce, such a birth and death law as will enable her to take her proper place among, not only foreign countries, but her immediate neighbors in the Registration Area of the United States, to the end that sanitary science can be advanced, preventive medicine be improved, the legal rights of every citizen be better protected, a proper foundation be laid for the working out of many social problems of vital importance, the health of every citizen be better protected and life prolonged.

18. Hemolytic Jaundice.—Thayer shows that the studies the last several years have brought out a fairly defini clinical syndrome, that of acholuric jaundice associated wi splenomegaly and fragility of the red blood-corpuscles. its purest form, this group of symptoms is manifested in sharply defined disease picture, congenital, often famili splenomegalic jaundice. It is probable that many of Gilbert cases of chronic simple jaundice with splenomegaly as w as of Hayem's infectious splenomegalic jaundice are exampl of the disease. A similar condition is, however, not infrequently encountered in adult life. In these so-called acquired cases the symptoms are, as a rule, considerably more acute and severe than in the congenital malady. The syndrome has, moreover, been found in a variety of other instances of non-obstructive jaundice associated with various infections or poisons. What the essential primary element in these cases may be, is not at present clear. Most important is the recognition of those apparently idiopathic examples of acquired hemolytic jaundice simulating pernicious anemia, cholelithiasis, the so-called splenic anemias or indeed, icterus gravis; most important because of the fact that the recognition and persistent treatment of some of these patients with iron may bring a great improvement, and perhaps permanent recovery. The recognition of this syndrome has opened again, and in an interesting manner, the question as to the possibility of a purely hematogenous jaundice. The methods of studying the corpuscluar resistance necessary for the diagnosis of such cases are, of course, too delicate for use by the busy practitioner, but they may be carried out easily in any well-equipped laboratory. In the severe acquired forms, rest in bed and t other adjuvants suitable for the treatment of any gra anemia should be adopted. In congenital hemolytic jaundi recovery is unknown, but a temporary improvement in t anemia may be obtained by persistent treatment with iro In acquired hemolytic jaundice long continued treatment m result in apparent, perhaps, indeed, in complete recover This is a very important fact when one reflects on the futilit of treatment with iron in Addisonian anemia, a malady whi may so closely resemble this syndrome.

37 *Malarial Pigment (So-Called Melanin): Its Nature and Mo of Production. W. H. Brown, Madison, Wis.

28. Cardiac Hypertrophy.—Stewart deals with first, the development of the reactive processes known as hypertrophy, in point of view of time after the establishment of a condition favorable to its onset; second, the question of co-hypertrophy; and third, the relation which the altered muscle bears to the normal. He found that hypertrophy induced by the production of aortic insufficiency involves all the chambers of the heart. The greatest absolute increase in weight is in the left ventricle. The remaining segments, arranged in the order of decreasing increments are septum, right ventricle and auricles. The greatest relative increase is also in the left ventricle, but the auricles show a relative hypertrophy greater than that of the septum or right ventricle. The co-hypertrophy of the auricle is not due to an altered venous pressure, but results from an increased force of auricular systole. The heart shows an increase in weight within one week after the production of aortic insufficiency. The increase in weight is due only in part to an increased water content.

34. **Effect of Pregnancy on Implanted Embryonic Tissue.**—Rous found that grafts of embryonic tissue, obtained at operation and implanted in the mother, will grow well in case she no longer carries young. The growth is no more rapid than that in favorable non-pregnant aliens, but persists for a longer period without retrogression and results in a greater variety of tissues. The superiority of auto-transplantation over iso-transplantation is responsible for this fact. No evidence of a specific "growth-substance" peculiar to the pregnant state is furnished by the experiment. When a mouse is implanted with embryonic tissue from its own uterus, and still carries developing young, the fate of the grafts is very different from that just described. They are vascularized from the host but fail to grow or differentiate. Yet they do not die, and after pregnancy is concluded they may start to grow. The finding is strikingly like that of others of implanted tumor in pregnant hosts. It seems probable that some general factor affecting the growth of implanted tissues is here concerned.

36. **The Estivo-Autumnal Parasite.**—The description of two distinct types of estivo-autumnal crescentic parasites given by Craig, Rowley-Lawson has been unable to confirm. She says that the crescentic parasite is throughout the entire existence extracellular (i. e., not without the substance of the red corpuscle, but attached to its surface). It develops from the familiar small ring-form parasite, retaining a circular contour until fully matured. The very young ring-form parasite has no capsule; the macrogamete has one during its development and sexual activity; while the microgametocyte has it only during its development. The sexual cycle of the crescent may occur in the circulating blood of its human host. The cycle is probably very rapid, for practically the whole cycle can be seen in a few smears taken from one puncture. This microgametocyte, or male, develops a flagellum (microgamete) which, after the parasite has assumed the crescentic phase, leaves the body of the parasite and enters the body of the macrogamete, or female, during its existence as a round body. Fertilization is then accomplished. The microgametocyte, after the escape of the flagellum, shows evidence of degeneration and is probably cadaveric. After fertilization, the macrogamete assumes the crescentic form, reaches the reproductive phase and undergoes sporulation, the product of which appears to be the small ring-form parasite. Renewed infection of the red cells then takes place.

That the sexual cycle is not seen oftener in the circulating blood of man, Rowley-Lawson believes, may be due to one or more of the following reasons: (a) The process of reproduction may be and probably is very rapid (some forms of protozoa are exceeded in rapidity or reproduction only by bacteria). (b) The cycle may usually take place in some of the internal organs. (c) It may be that the sexual cycle occurs in the peripheral blood only at intervals, when it becomes necessary for the parasite to renew its exhausted vitality. (d) The occasional occurrence of the sexual cycle in the circulating blood may be due to some slight chemical change in the composition of the host's blood-serum. She finds no good evidence of conjugation-forms in estivo-autumnal malaria. She found some of the young ring-form parasites in close approximation or overlying each other. As the sexual cycle does not take place in the blood of man, such a process of conjugation would seem unnecessary, unless it occurred as an atypical process. The fact that the crescent is more resistant to quinin than the other varieties of malarial parasites might be explained by the presence of a capsule which appears to protect the parasite, certainly during the sexual phase and probably during the "resting" period (when not undergoing sexual changes). The youngest form of ring parasite shows no evidence of encapsulation. This may explain the fact that quinin is best administered just before the paroxysm when the parasite is undergoing segmentation.

37. **Malarial Pigment.**—Two important methods for the study of malarial pigment are described by Brown: (a) a method for obtaining a solution of malarial pigment from fixed tissues without the removal of a trace of hemoglobin from the red blood-corpuscles; (b) a method for obtaining an iron reaction in malarial pigment. By comparing the bleach reactions and solubility of melanins and malarial pigment, the dissimilarity of the two classes of pigments has been demonstrated. The spectroscopic examination of a solution of malarial pigment proves conclusively that the pigment is hematin. It is suggested that the action of a proteolytic enzyme of the malarial parasite on the hemoglobin of the red corpuscle is the most probable mode of elaboration of malarial pigment. The difficulty with which the human organism disposes of malarial pigment indicates that the production of hematin cannot be considered as a normal intermediate process in the formation of bile pigments from hemoglobin.

46. **Intratracheal Insufflation of Air and Ether.**—This paper is devoted to the subject of anesthesia itself, with special reference to the technic of the method. The apparatus used for intratracheal insufflation is described. Elsberg has so far anesthetized about thirty patients by intratracheal insufflation. Some of them were operated on for intrathoracic disease, many for abdominal or other affections. He has found the anesthesia very useful in operations on the head and neck, as the anesthetist was never in the operative field or in the way of the operator or his assistants.

47. Abstracted in THE JOURNAL, Jan. 28, 1911, p. 298. Appended to this paper are the abstracts of 264 cases recorded in the literature.

48. **Diverticula of the Lower Bowel.**—Fifteen cases of diverticula of the lower bowel were studied by Wilson up to Dec. 1, 1910. Three of these were cases of peridiverticulitis. In these the inflammation did not involve the mucosa. Its presence in the peridiverticular fat was apparently due to leakage through the thin-walled diverticulata—a condition similar to that seen in old umbilical hernias. The symptoms were those of peritonitis or obstruction from pressure. In four cases carcinomata had developed in the diverticula, probably from epithelium segregated by chronic inflammation.

49. **Volvulus and Strangulated Hernia.**—Miller presents two cases, with abstracts of the cases reported since Knagg's paper in 1900. Volvulus, he says, may produce *in a hernia signs* and symptoms which accurately simulate hernial strangulation; or it may be associated with actual strangulated hernia. Volvulus, in either association, may readily escape recognition; it is probably contributing heavily to the mortality of strangulated hernia. The diagnosis before operation is usually exceedingly difficult: there are, however, [illegible] very suggestive features, viz., advanced age, [illegible] *of hernia for*

many years, shock out of proportion to the signs about the rupture, and marked abdominal pain and tenderness with occasionally a palpable mass. The diagnosis at operation depends on careful observation, there being certain signs which are pathognomonic; an operation undertaken for strangulated hernia must demonstrate absolutely the strangulation. Volvulus proximal to actual strangulated hernia apparently offers no sure means of diagnosis other than routine abdominal exploration—a procedure which is manifestly not to be recommended.

50. **Fecal Continence After Colostomy.**—The fundamental idea of the method Marro applies consists in causing the proximal end of the resected intestine, properly mobilized, to cross a subcutaneous tunnel, which is parallel to the exterior border of the rectus muscle, in such a way that a simple belt (that of the drawers, for instance), going round the trunk and passing over the iliac wings, should play the part of an effectual and comfortable band of compression on the intestinal segment running between skin and aponeurosis. Such a compression may be rendered more active by a contraction of the abdominal wall, in the moments in which the individual feels the need of it, e. g., in diarrheic attacks and during active peristalsis of the colon. Theoretically, its function would thus imitate well enough the natural function of the sphincters. Three cases are reported in which the method proved quite successful.

57 *Id. M. Prince, Boston.
58 Raymond—His Life and Example, 1844-1910. W. B. Swift, Boston.

54. **Hysteria and Modern Psychoanalysis.**—According to Friedländer, we do not possess a therapy applicable in all cases of hysteria. The cathartic method of Breuer and Freud, from the theoretical standpoint, has been very fruitful for the psychology of hysteria; it is of practical value in certain cases of traumatic hysteria. The association studies of Jung and others deserve critical consideration. The psychoanalytic method, he says, is surely not the only one that is of value in the treatment of hysteria, neurasthenia or obsessions. In so far as the method is connected with the detailed discussion of sexual matters and perversities, it is justly rejected by many authors. Psychical treatment, as it is practiced by those who do not belong to Freud's school, accomplishes as much as sexual psychoanalysis, but it must be aided according to the particular case by general therapeutic measures applicable to functional neuroses and psychoses. (Training in work, hydrotherapy and electrotherapy, dietetics, etc., and, under certain conditions, hypnosis.) The procedure of those authors who carry on a propaganda in lay journals about this method of treatment, which at best is not proved, and which is rejected by many, Friedländer holds deserves emphatic disapproval.

55. **Fundamental States in Psychoneurosis.**—Sidis says that in all his phobia cases, he found as the basis of the morbid condition the primitive instinctive fear of the unknown, of the unfamiliar, a fundamental fear instinct rooted in the impulse of self-preservation, and an overdeveloped sense of the mysterious. The recognition of these fundamental states by the psychopathologist and their disintegration by treatment are of the utmost importance for psychopathology and psychotherapeutics. The fear of the mysterious is the beginning of phobia.

5e prolonge**The Mechanism and Interpretation of Dreams.**—J [illegible] it up to the present no one who has taken the trouble to acquire the psychoanalytic method has failed to confirm Freud's theory in all essential particulars. Prince, on the other hand, holds that no one who has shown by his writings that he is thoroughly trained in and conversant from first-hand knowledge with all the phenomena of abnormal experimental and functional psychology has accepted Freud' theory.

64 *An Unusual Case of Foreign Body in the Eye. R. S. Lamb Washington, D. C.

64. **Foreign Body in Upper Eyelid.**—The patient in thi case was suffering from a condition of the left eye which t all appearances was a trachoma with pannus, or possibly a kerato-iritis with vascularization of the cornea of such lon standing as to have caused the beefy-looking inflammation o the upper lid. He gave a history of having got a piece o hair in the eye and of having it removed at one of the hospitals, since when the eye had been better and worse, bu always somewhat inflamed. After bleaching with cocain an adrenalin as much as possible, a thorough search failed to discover any sign of any foreign substance, and Lamb conclude it was a case of syphilis, even though the patient denied th knowledge of having been infected. He treated him accordingly internally with Donovan's solution, external mercur rubs and locally with yellow oxid and atropin sulphate 1 pe cent., having him use smoked glasses. In the course of a fe days the man was better, but complained now of a mor marked scratching sensation, whereupon Lamb took cocai and adrenalin, bleached as best he could, and searched carefully and long, finally locating in one of the fleshy masses of the upper lid, near its center at the upper border of the cartilage, a small black point. The surrounding flesh was removed and a wiry hair ¼ inch long was pulled out. It had been imbedded in the lid at right angles to its surface, and so whenever the granulating flesh grew smaller the hair presented itself and began again the process of scratching the cornea.

70 *Chronic Family Jaundice. W. Tileston, New Haven, Conn. and W. A. Griffin, Sharon, Mass.

65. **Unilateral Hematogenous Infection of the Kidney.**—Brewer has encountered fourteen cases of this severe type of unilateral infection. Of these, two patients were untreated; both died within twelve days. Four patients were treated by nephrotomy and drainage; all died shortly after operation. Eight were treated by early nephrectomy; all recovered. He also reports a number of cases of some of the milder types of the affection in which measures less radical than nephrectomy are indicated. These cases, like the preceding group, often simulate in their symptomatology, appendicitis, cholecystitis, or abscesses of the liver. If unrecognized and unrelieved by appropriate treatment, they go on to the formation of the more definite and more easily recognized lesions, as renal abscess, perinephritic abscess, pyelonephritis, or pyonephrosis. The lesions in these cases, while the same in general character as in the severe type, are fewer and more scattered, and the amount of renal tissue involved is less. Stripping the capsule from the organ when the lesions are small, or combined with the openings and drainage of cortical abscesses or areas of necrosis when present, constitutes the best treatment. In certain instances, when the treatment has been delayed too long, the suppurative process continues and

a secondary nephrectomy may be necessary. Brewer has operated in about twelve cases of this type, and while there was no postoperative death in the series, on one occasion he was obliged to perform a secondary nephrectomy for advancing sepsis; in another patient in whom the function never returned, he performed nephrectomy for persistent renal neuralgia; and in at least one other case a persistent pyelonephritis has resulted. The end-results in most instances, however, have been satisfactory.

There is still a milder type of the disease, the so-called idiopathic pyelitis, which, as a rule, requires no treatment other than rest, hexamethylenamin, and the ingestion of a large amount of pure water. The symptoms are mild in character, and when on the right side are often mistaken for a subacute appendicitis or cholecystitis. The disease may or may not be ushered in by a chill. When present, the chill generally indicates a severe type of infection. The initial rise of temperature is high, generally 104 F. (40 C.), or 105 F. (40.5 C.); pulse is frequently 120, or above. The toxemia is marked from the first and, with the high fever, suggests often an acute grippe, lobar pneumonia, or one of the exanthemata. Then follows a more or less vague pain in the abdomen, or flank, corresponding to the side of the lesion. Tenderness and muscular rigidity over the region of the appendix, or gall-bladder, leads often to error in believing one of these organs to be the seat of the disease. As the urinary secretion from the infected kidney is greatly diminished, and is largely diluted by the abundant secretion from the unaffected organ, the mixed urine, when passed or drawn from the bladder, is often quite normal in appearance, and the slight trace of albumin, blood and pus, is often overlooked unless a more than ordinary careful examination is made. The one pathognomonic sign present in all cases is a marked unilateral costovertebral tenderness.

96. **Postoperative Conditions After Intubation.**—Of a carefully recorded series of 437 intubations for laryngeal diphtheria, in 80 per cent. of which the patients were alive when the tube was removed, Shurly has been able to locate and examine thirty of the older children. All these patients had clinical laryngeal diphtheria. The age varied at operation from seventeen months, the youngest, to eleven years, the oldest. The smallest dose of antitoxin given was 1,000 units; the largest 4,000 units. The time during which the tube was worn consecutively was from forty-eight hours to one hundred and twenty-four hours. No instance of retained tube occurred in any of these cases. Four patients required reintubation. In one case intubation had been attempted by two other operators during some hours, without success. Other cases of diphtheria appeared in the same family or in the neighborhood, from which the contagion could be traced in five of these cases. The subsequent statements show the extent of susceptibility of infectious or contagious diseases in these cases, as follows: Measles, ten cases; chicken-pox, four cases; mumps, four cases; whooping-cough, two cases; scarlet fever, three cases. Partial or complete aphonia remained for from one day to seven years after the removal of the tube. "Throat disease" was claimed in ten cases. Four patients were partial, periodic or complete mouth-breathers. Other adenoid symptoms were present in six cases. Lung or heart disease was noted in six cases. Affections of the ears were acknowledged by four. A greater susceptibility to coryza was observed in seven cases. Dyspnea, asthma or hay fever was present in two cases (from adenoids).

The examination was made five years after intubation in one case, and from eight to twelve years in the other cases. Nasal conditions requiring operations were: Deflected septum, four; intumescent and hypertrophied turbinates, two. In eight nasopharyngeal conditions required operation (tonsils). No laryngeal conditions required operation. Enlarged cervical glands were found in nine cases. Thickening of the interarytenoid fold was observed in four cases. Every patient in this series was intubated for laryngeal diphtheria. Shurly concludes that intubation in laryngeal diphtheria is required more frequently when marked tonsillar hypertrophy exists, and that pathologic adenoids and tonsils are prominent predisposing factors in diphtheritic infections of the larynx. No deleterious effects of antitoxin were noted. Laryngeal paralysis is extremely rare after intubation, he states. Scar tissue was observed in two cases. The cicatrix was insignificant and apparently produced no modification in function. No case of laryngeal paralysis was found, although one with motor insufficiency was observed. Children developing laryngeal diphtheria show, Shurly says, a marked tendency to other infections in childhood. So-called chronic catarrhal inflammation of the upper respiratory tract is usual after severe diphtheria.

105. Abstracted in THE JOURNAL, Nov. 19, 1910, p. 1838.

108. **Surgical Anesthesia and Blood-Pressure.**—The authors made a study of the blood-pressure and its relations to the pulse rate during administration of various anesthetics, hoping to determine by instruments of precision the onset of untoward symptoms. In all cases, the pressure was taken the day previous to operation, one hour before operation, at the starting of the anesthetic, every five minutes during the operation, one hour after the operation, and the day following; the pulse rate being recorded each time the pressure was taken. In some cases the Stanton instrument, in others the Tycos, was used. They learned that when ether is used the blood-pressure rises at first in nearly every case. When the ether was preceded by ethyl chlorid the pressure remained unchanged during the few moments of ethyl chlorid administration, but when the ether was started, the pressure rose as in the cases in which ether alone was employed. When the skin incision was made it was found that there was a fall in the blood-pressure, which was more marked if the patient was but lightly anesthetized; this fact was also noted in operations in which the peritoneum was incised. One point already well known was once again confirmed, namely, that if the ether was pushed to the point of very deep anesthesia during the operation the blood-pressure fell in proportion to the degree of ether saturation. They conclude that artificial anesthesia causes in many cases a marked alteration in the ratio between the blood-pressure and the pulse rate; this is augmented by anything that produces shock to the nervous system during the operation, notably incision of the skin or peritoneum or drawing on the pedicle of an organ. If at the time of this shock anesthesia be light, the shock will not be so marked as if the patient were under deep anesthesia. In certain operative cases in which the patients show abnormal blood-pressure, on the one hand whether it be high or low, or on the other hand present evidences of cardiac fatigue or actual myocardial weakness, a suitable course of treatment would likely be to diminish chances of circulatory complications both during and after operation to a considerable degree.

113. **Death and Disability.**—From the opening of the new Montreal Maternity, Oct. 17, 1905, to Oct. 1, 1909, there were treated at that institution 2,634 patients. Of these thirty-five died. It is admitted that this 1.33 per cent. unexpurgated mortality is unusually high, but no patient seriously ill was refused admission, even postpartum, and during the entire four years no patient whose death seemed imminent was allowed to be removed from the hospital. The causes of death were one or other of the forms of toxemia, 40 per cent.; infection, 37 per cent.; and all other causes, including placenta prævia, 23 per cent. Of thirteen patients dying as the result of infection, seven came to the hospital after treatment outside; four had been delivered; two partially delivered; and in one, a placenta prævia, had been repeatedly examined. Another patient with a streptococcus sore throat died of peritonitis within a few hours of delivery, and the child likewise died of streptococcus septicemia. One case of Cesarean section terminated fatally after operation, as did also one case in which pubiotomy was done. For the three remaining cases there is no excuse offered by Little. Two of the patients were delivered spontaneously and one by a low forceps operation, all within two weeks of one another. He says that while laceration of the cervix and of the perineum may account for a certain number of the conditions noted, one further feature in the general management of cases postpartum seems to be accountable for much later distress. This is the custom of tightly bandaging the patient after delivery, and leaving her in such a condition that she is comfortable only when lying flat upon the back. This procedure has, he believes, three distinct disadvantages. In the first place, it absolutely opposes any involution of the round ligaments, which would tend to draw the uterus forward; it prevents the falling forward of the uterus on the bladder, with the consequent tendency to spontaneous micturition; and, finally, tends permanently to hold the uterus back, so that the anterior lip of the cervix is drawn forcibly from the more or less fixed posterior lip, and laceration, if present, is prevented from healing by the formation of scar tissue in the angle of the wound. Not only does this permanent opening of the cervix cause discomfort later, but it is usually associated with a permanent displacement of the uterus. Opposed to these three marked disadvantages of the binder, there is, in Little's opinion, no definite advantage to be claimed for its use.

7 *Poisoning After Small Doses of Acetyl-Salicylic Acid (Aspirin). C. Morgan.

1. **The Choice of a Diuretic.**—The citrates, acetates and tartrates of sodium, potassium and ammonium, Smith says, increase the osmotic pressure of the blood and draw water from the tissues into the blood stream. They do not, therefore, irritate the kidneys, and may be used without fear, he declares, even when these organs are acutely inflamed. It is important that when taken, these drugs should be well diluted, for their action on the kidneys is thus rendered more certain; and it is useful to combine them with spirits of nitrous ether, which, on account of the nitrite of ethyl it contains, is a useful agent in causing dilatation of the afferent vessels of the kidney. In cases of renal dropsy, if the illness be acute, the saline diuretics are the only remedies of the kind which can be given without risk of further injury to the affected organs. That they may act with success, it is of the highest importance to make sure that there is no obstruction to the portal circulation through the liver. A preliminary dose of blue pill followed by a liberal saline aperient is always advisable; and if during the course of the treatment the action of the remedies is found to be getting uncertain or ineffectual, especially if the arterial tension be high, a repetition of the dose will prove to be of service. In all cases, a careful watch should be kept on the work of the bowels, and their action should be encouraged by sufficient doses of a watery aperient every day or every other day, such as the compound jalap powder. To be effectual, this powder must be ordered in adequate dose, and its action can be rendered more energetic by the addition of jalap. In the treatment of adults, elaterium is a useful remedy, but in early life its action is uncertain, and the jalap powder is to be preferred in the case of a child.

The remedial action of pilocarpin Smith has not found very satisfactory. When the acuteness of the attack subsides and the complaint begins to settle down into a chronic course, Smith advises the use of some of the special drugs which act directly on the secretory apparatus, such as digitalis and caffein. In the choice of a diuretic in cardiac dropsy, we must bear in mind that the cause of the edema lies primarily in the chest, and not in the abdomen, and that remedies which act on the kidney are of little or no value unless combined with others which strengthen the action of the heart. We must remember, too, that when blood-pressure is low, drugs which tend to lower arterial tension still further are not only useless, but become an actual source of danger. Digitalis, strophanthus, convallaria, squill and some other drugs act as cardiac tonics, but digitalis, as a rule, is the most prized. Its efficacy as a diuretic may be further enhanced by giving it in combination with other drugs which promote diuresis by different means. The citrate of caffein is, perhaps, the most useful of these drugs in ordinary cases. The combination is further strengthened by the addition of sweet spirits of nitre, as dilator of the afferent vessels of the kidney, in doses of from 30 to 60 drops. In giving this combination it is best to prescribe the digitalis alone or in conjunction with the nitrous ether for two or three days before adding the caffein, as digitalis requires to be taken several days before its effects become noticeable. The dose of caffein should be moderate (from 2 to 3 grains two or three times a day), as stimulation of the epithelial cells of the kidney should always be looked on as a temporary measure which is not to be abused, and may do harm if carried to excess.

The infusion of broom-tops (scoparius) is another safe remedy which may be usefully combined with digitalis. It contains spartein, an alkaloid which has an action on the heart similar to that of caffein, and also contracts the afferent vessels of the kidneys. An ounce of the infusion given in conjunction with a dram of the infusion of digitalis, from 30 to 60 drops of spirits of nitrous ether, and from 60 to 90 drops of the acetate of ammonia solution is a diuretic of great value, both in cardiac dropsy and in that which results from renal disease after the acute stage is at an end. Nitrous ether is one of the most valuable diuretics and can be included in most combinations; but it is incompatible with salicylates, and also with antipyrin and any drug containing tannin. Its good effects are most noticeable when given in combination with acetate of potash, digitalis and squill.

When progress seems at a standstill, there are two drugs, either of which will often bring about a welcome change in the situation—tincture of cantharides, from 2 or 3 to 10 minims, and mercury. Either calomel or blue pill may be employed, but Smith prefers the latter. Mercury is to be avoided, he says, if renal disease be present, and when given should not be pressed if diuresis does not result in the course of three or at the most four days, for it is in such cases that the system may possibly be unfavorably affected by the treatment. Smith has given blue pills in doses of 3 grains, three times a day, in many cases, both to young people, 10 or 12 years of age, and also to the adult, and has found it to be very well borne and to produce free secretion; but when diuresis has been fully established, he has made it a rule to discontinue the mercury and replace it with a mixture of caffein and spirits of nitre with infusion of broom-tops. If the mercury be continued too long there is the risk of setting up stomatitis; and in any case it is wise while the remedy is being taken to wash out the mouth several times a day with a suitable antiseptic solution.

2. **Serotherapy of Diphtheria.**—Goodall is averse to using antitoxin as a prophylactic. He says that not only might it happen that the person treated was especially and peculiarly susceptible to the action of serum, even if he was not known to be asthmatic, but supposing he was not naturally susceptible, it would not be unlikely that by the injection one would render him artificially so, in which case, if subsequently it were found to be necessary to use antitoxin remedially, he would run the risk of undergoing a very unpleasant illness. There are outbreaks of diphtheria in institutions for the care of children, in which, Goodall thinks, the use of antitoxin as a prophylactic, given cautiously and after due inquiry into the children's life history, may be justified. But he is strongly of the opinion that an indiscriminate use of serum as a prophylactic is not only unnecessary, but unjustifiable.

3. **Argyll-Robertson Sign in Cerebral Syphilis.**—In a recent analysis of forty-eight cases of syphilis of the brain and twenty-one of the cord, sixty-nine in all, Clarke obtained the following results with regard to the Argyll-Robertson pupil: In every case there was a clear history of syphilis, or some undoubted syphilitic lesion, and, in addition, in the later cases Fleming's test was positive. Out of the sixty-nine cases, the Argyll-Robertson pupil was present in two of cerebral syphilis. One patient was a man, aged 32, apparently with syphilitic meningitis of the convexity; he had headaches, was apathetic, forgetful, depressed, with indistinct or slightly slurring speech and exaggerated knee-jerks. He showed

no improvement under treatment, and his symptoms suggested the possibility of an early stage of general paralysis. The other patient was a woman, aged 45, who suffered from right facial paralysis twelve years ago, five years ago was under Clarke's care for cerebral syphilis, with right hemiplegia and Argyll-Robertson pupil, and has developed on the hemiplegia a typical tabes dorsalis. In another patient there was paralysis of the right third nerve, with complete iridoplegia, the left pupil did not react to light on admission, but recovered fully under treatment. In six patients the pupil reaction to light was sluggish, but not absent, and in three it became much brisker after treatment. One patient suffered from epileptiform fits, both general and localized, with headache and vomiting; two from hemiplegia, with headache and vomiting; one from meningitis of the convexity, with hemiparesis, cranial nodes and double optic neuritis; the fifth was a patient with hereditary syphilis, with cerebral symptoms and optic neuritis; and the sixth was a patient suffering from syphilitic cerebrospinal meningitis, with hemiplegia and intense optic neuritis. Optic neuritis, in varying intensity, was present, therefore, in three of the six patients with sluggish reaction; optic neuritis does not, of course, abolish the light reaction.

Of the twenty-one spinal cases, in one the light reaction was sluggish, and in two the Argyll-Robertson sign was present. Of the latter, one was a rather remarkable case. The patient was a man, aged 32, who had had left hemiplegia two years before, from which recovery was not complete. When admitted, he was dull, apathetic, and had some mild delusions as to place and as to his circumstances. The cord affection corresponded to Erb's syphilitic spinal paralysis, and was of very gradual onset, with the usual affection of the bladder, great exaggeration of deep reflexes, and double extensor plantar reflex. The pupils were very small. Under mercurial treatment he made an unexpectedly good recovery, both as to his mental and physical state, and was able to return to work. The Argyll-Robertson sign persisted. In the other case the cord affection was of the same kind, with no affection of sensation, no ataxy, and no symptoms, except slight incontinence, beyond those clinically referable to degeneration of the pyramidal tracts; the disease was also of very gradual onset. It is an interesting point that the only cases presenting the Argyll Robertson sign among Clarke's cases of syphilitic disease of the cord are cases belonging to the clinical group of syphilitic spastic paraplegia, first described by Erb.

7. **Poisoning After Small Doses of Acetylsalicylic Acid.**—Morgan reports a case of a rare idiosyncrasy to acetylsalicylic acid, a vasomotor neurosis, allied to angio-neurotic edema, but without visceral symptoms. Half an hour after taking 5 grains of the drug, the patient noticed that her lips were swollen. The swelling spread rapidly all over the face, and finally the tongue and throat became affected. In twenty-four hours all swelling had disappeared. Several months later the patient was told to take the drug again. Within an hour she became very anxious and restless, her face was enormously swollen, especially the eyelids, lips and nose. The tongue was swollen so much that it was with difficulty protruded between the teeth. The fauces also were much swollen, and she complained of great discomfort in her throat. There was no headache, but she complained of her head being "funny and uncomfortable." On her hand and forearms there was an urticarial rash. The pulse was 110, feeble. The pupils were moderately dilated, and the conjunctiva of both eyes were bloodshot. Next morning the swelling was much less, but the eyelids were still very puffy, and the vessels of the conjunctiva engorged; in fact, this symptom did not disappear for a week. The pulse was 80, and she felt well.

10. **Treatment of Injuries Caused by Electricity.**—There are two main theories as to the cause of death in electric shock: (1) inhibition of the medulla oblongata, leading to arrest of respiration, followed by cessation of the beat of the heart; (2) death directly from the heart without the intermediary of respiration. Oliver's experiments seemed to show death to be of cardiac origin. After death from electric shock there is usually rigidity of the muscles. The heart is flaccid, especially the right ventricle, which contains dark fluid blood. The left ventricle may be empty. The lungs may show nothing abnormal, or there may be signs of congestion, if death was not immediate and artificial respiration had been resorted to. The pupils are dilated. The brain and spinal cord may be congested, and the abdominal veins and viscera full of dark blood. There may be hemorrhage in the brain and petechial hemorrhages in the pleura and pericardium. Although the blood is usually fluid, it is occasionally coagulated. On spectroscopic examination, it is found to contain both oxyhemoglobin and reduced hemoglobin. Chromolytic changes in the cerebral cells were found in two cases reported by Oliver. For slight shock followed by recovery no treatment is required. For burns the application of boric acid compresses, or charcoal poultices, if there is much destruction of tissues, is called for. When an injured workman is in contact with or cannot lose grip of live metal, the greatest care must be exercised in touching his body, for any attempt to separate the two might be followed by a disastrous shock to the person rendering assistance. Under any circumstances the breaking of the current means a fresh shock to the individual concerned. Once the circuit is broken, should there be no signs of life, the body must be placed on its back and artificial respiration immediately resorted to and continued for a considerable time, even if there is no quick response. In Oliver's experiments he succeeded in resuscitating animals whose heart beats and respiration had ceased for several minutes.

11. **Inoculation of Tuberculin with Local Anesthesia.**—The only question on which Crowe attempts to throw light is whether the inoculation of tuberculin produces its effect in any degree by stimulating afferent nerve endings at the site of the injection. His procedure has been to combine a considerable proportion of a 4 per cent. solution of beta-eucain lactate with varying doses of tuberculin in cases of phthisis under treatment by vaccines. Daily observations of the opsonic index were recorded during the whole course of the investigation, and as far as possible the blood specimens were taken at the same hour of the day. There was a distinct difference in the response to an inoculation of tuberculin in phthisis if eucain was combined with the dose. The chief proof of this rests on the form of opsonic curve which follows such doses as compared with doses in which no eucain was given. There is a possibility that an inoculation of tuberculin produces its effect, in part, by stimulating the central nervous system. Such stimulation may take place at the site of the inoculation.

32. **Human Milk and Diarrhea.**—Maloney found that diet and exercise seem to have little or no influence on the sugar and fat content of human milk. Menstruation may coincide with marked impoverishment in fat. The amount of fat in milk varies as the hour and phase of the food, and also according to individual peculiarities of mothers; a rigorous maternal régime does not appreciably influence the richness of the milk in fat; but an impoverishment may appear simultaneously with the menses. The lactose of human milk is remarkable for the constancy of its amount, which seems indifferent to feeds, days, régimes, and menstrual periods. In sixteen milks examined by Maloney, varying in age from 3 weeks to 7 months, the amount of lactose was only once below 5.28 per cent., and twice above 6.50 per cent. The average age of these milks was 3.12 months, and the average percentage of lactose they contained was 5.82. The percentage of lactose usually attributed to human milk seems, therefore, to be too high. Diarrhea in breast-fed infants whose feeding is carefully directed may persist in some cases owing to excess of fat in the milk; in others, either owing to the presence of an abnormal laxative principle in the milk, or to the undue irritability of an otherwise normal intestinal tract. In none of Maloney's cases could excess of sugar be incriminated. A state of chronic diarrhea prevailed in seven nurslings whose feeding was carefully directed, and whose food was not abnormally rich either in fat or in lactose. Regulation of the mothers' régime did not influence this diarrhea. From three to six, usually four, motions occurred daily; they were characteristically of a light yellow color, semifluid, inoffensive, and without curds. The infants steadily gained in weight, were apparently content, enjoyed an average amount of sleep, and were not unduly querulous. Four of these babies had a history of a persistent tendency of looseness of the bowels from birth. This benign diarrhea resulted, therefore, says Maloney, either from some relatively harmless laxative principle in the mother's milk, or from an excessive irritability peculiar to the infant's intestine. If, on transferring the child for a time to a healthy wet-nurse whose own charge was progressing normally, the diarrhea should cease, the mother's milk would be proved abnormal; if, however, it should continue, the infant's intestine would be proved hypersensitive. The three or four motions each day represented the child's habit. The only treatment required was to discourage weaning and to reassure the mother; for her benefit a little bismuth was usually given to the child. Eczema may arise in nurslings from overfeeding, from richness of the milk in sugar, and from the influence of a faulty maternal hygiene on the chemical composition of the milk. But undoubtedly it may, as in Maloney's six cases, exist in the absence of overfeeding and when the milk contains only a normal amount of sugar. It may remain unaffected by the sacrifice of all the maternal indiscretions of diet. Probably it may arise independently of its commonly alleged factors; yet the co-existence of diarrhea and eczema in three babies makes Maloney reluctant to exonerate the milk-supply in any case of eczema occurring in a nursling.

54. **Continuous Stream of Oxygen in Treatment of Diffuse Peritonitis.**—THE JOURNAL, May 28, 1910, page 1829, mentioned encouraging results that have been obtained by flushing the abdominal cavity with a constant stream of oxygen which escapes through drains at the lowest points. Banzet's experience in a case of diffuse peritonitis in a woman of 30, confirms the advantages of this simple measure. Besides the biologic stimulating effect of the oxygen, the gas helps, he asserts, to expel all morbid products and fluids. From the previously almost dry drains poured a flood of serous and purulent fluid after the jet of oxygen was turned into the abdomen. Banzet did not have at his disposal a tank with a stopcock to regulate the flow, and consequently he had to apply the oxygen from rubber bags, a bag containing 20 liters taking about half an hour to empty itself. The drains should not be perforated, he says, and he found that the oxygen acted more effectively when it was introduced through the different drains in turn.

56 *Combinations of Drugs in Therapeutics. (Les associations médicamenteuses et le renforcement de l'activité d'un médicament par une autre substance ajoutée à petite dose.) P. Chapelle.

55. **Estimation of Hydremia in Nephritis and Cardiac Edema.**—Widal has long insisted on the importance of daily weighing of patients with a tendency to failing compensation and chronic kidney trouble as it is thus possible to detect retention of fluids before the edema becomes clinically manifest. The blood itself early becomes diluted, and he has found that the refractometer is a sensitive index of the degree of this dilution. He here gives the clinical findings in a number of cases in which both the changes in weight and the refractometric hydremia index were recorded in parallel tracings and the various types of the curves determined for interstitial and epithelial nephritis and in heart disease alone or associated with kidney disease. The findings are also recorded during and outside of courses of salt-poor dieting and administration of digitalis. They show that the serous infiltration of the tissues is accompanied by corresponding dilution of the blood; an "edema of the blood," he remarks, is the natural accompaniment of the edema of the tissues. As the weight declines, the refractometric index rises, but the change in weight becomes apparent first. The refractometer shows that as the excess of fluid is thrown off first from the tissues, the blood remains diluted for a time, and only later becomes concentrated. The action of digitalis is shown by the refractometric findings as it causes a sudden influx of the edema fluid into the blood. The fluids impregnating the tissues interfere with their normal nutrition and when the fluid is drained

away part of the constituents of the cells are washed away with it, and the patient emerges from the course of treatment much thinner, but recuperates afterward like a typhoid convalescent. The increase of weight later may be due to reaccumulation of the edema, and this can be determined by the refractometer; if the curve persists within normal limits, there is no dilution of the blood and no paralleling edema of the tissues. The refractometric findings also reveal at once if the course of dechloridation has not been continued long enough; the drop in the index is a warning to abstain still longer from salt.

56. **New Combinations of Old Drugs.**—Chapelle reviews recent research which has shown that the therapeutic efficiency of certain drugs can be materially enhanced by addition of even a minute amount of some other drug. The data learned recently in regard to the action of ions, of the colloids and metallic ferments, superficial tension, radio-activity, anaphylaxis, immunity, etc., have thrown much light on biologic processes and have shown the infinite variety of conditions in which there is an unstable balance between the cellular elements and the media laving them, so that the possible increased efficacy of combinations of drugs no longer seems paradoxical. They open new horizons and virgin fields for applying the old weapons in new ways and combinations.

57. **Treatment of Gout and Rheumatism with Radium.**—His thinks that there are great therapeutic possibilities for internal medicine in radium treatment, his experience having shown the efficacy of radium emanations in a number of cases of gout and rheumatism as adjuvants to the ordinary measures. He gives the radium emanations usually by inhalation, having the patients stay for two hours daily in air containing from 2 to 4 Mache units, equivalent to 1,000 electric units. The apparatus used provides a stream of oxygen bubbling through a fluid containing the radium salt and saturated with its emanations, a ventilator distributing the emanations through the room. He regards it as important to distinguish between gout and rheumatism as the dietetic indications are important and vary widely. The only criterion is the presence of uric acid in the blood, and he deplores the fact that he knows of no simple and easy technic for detecting uric acid in the blood. The only reliable method, he states, is that of Krüger and Schmidt, applied to as much as 80 or 100 c.c. of blood. Since he has systematically investigated the blood by this method, he has had many surprises, finding that uricacidemia is evidently responsible for the frequent myalgias in the back of the neck, shoulders and lumbar muscles in many cases while they are of rheumatic origin in others. Many insidious and symmetrical affections of the smaller joints, which seem to be rheumatic, are shown by the blood-test, he asserts, to be due to uricacidemia, as also neuralgia, especially sciatica, in many cases. He hopes that a reliable unit for work with radium will soon be developed and possibly that some commoner substance may yet be discovered with radio-active powers. In conclusion, His remarks that old exostosis, indurations, loose bodies in joints and extreme atrophy of the muscles and similar irreparable conditions are not amenable to radium or any treatment; the best results may be anticipated in the more recent cases of not too long duration, in which the main changes are merely from infiltration of the joint capsule. See Ab. 3, page 700.

58. Practically the same article was published in the *Medical Record*, New York, Jan. 21, 1911.

59. **Shutting Off Part of the Circulation as a Therapeutic Measure.**—Tornai applied Klapp's suggestion to shut off part of the circulation as an improved method of giving anesthetics, but Tornai uses it without regard to any drug. He found that by applying a constricting band to arrest the venous circulation in the limbs, the heart had less than half the former area to serve and could work with so much less blood that its task was proportionately lightened, and it was thus given a chance to recuperate. He has applied this as a therapeutic measure in a number of cases, shutting off the circulation in the limbs for twenty or thirty minutes every morning for a week or so. The effect was striking, he reports, in cases of fatigue and dilatation from stasis of the right heart, the right ventricle being too weak to empty itself completely during the systole. By holding back part of the blood, the right ventricle was able to accomplish its task better, with less expenditure of energy, and was given a chance for rapid recuperation. The most striking benefit was obtained with mitral affections, but benefit was also realized even with degeneration of the myocardium and with beer heart, the tachycardia, arrhythmia and insufficient systole subsiding. After release from the constriction the pulse becomes slower and more regular. In the severer cases in which heart tonics fail, little can be expected from the constriction method, but he has obtained good results in a few exceptional cases even of this kind. The relief from the measure is so great that often the patients await its application with impatience. Diuresis is generally promoted, and there was profuse sweating in some cases as the constricting bands were removed; this must be done very slowly and gradually. He uses rubber tubing for the constricting band as for the Momburg technic. He attempted to enhance the action of drugs by this means, finding that a small amount had an immeasurably greater effect when the limbs were excluded from the circulation, but in order to accomplish this the arterial circulation in the limbs had to be arrested likewise, and the constriction kept up for an hour or more; the patients objected to this, so he has abandoned the method.

60. **Etiology of Cirrhosis of the Liver.**—Klopstock presents arguments to show that ascites is not always due to disturbances in the portal circulation, but is more liable to be the expression of chronic peritonitis. This theory throws light on the infectious and toxic factors in the origin of cirrhosis, and it also suggests that the Talma operation of omentofixation is not applicable in every case. The very fact that the ascites was cured immediately by this operation in a number of cases showed that the cure could not have been due to establishment of a collateral circulation as this requires time to develop. He knows of over 300 cases in which the Talma operation has been employed, but permanent benefit was obtained in only 30 per cent. of the 274 cases compiled by Bunge. It is adapted only for the cases in which the portal circulation is actually the causal factor.

61. **Subcutaneous Arthrodesis.**—Peltesohn reports three cases in which he followed Bade's technic of hammering an ivory peg into the joint. The outcome was a failure in every case, although all the wounds healed by primary intention, and there was no reaction of any kind on the part of the tissues to the presence of the foreign body. The trouble was in the ivory pegs which seemed to disintegrate; one broke, and in each case the ivory had to be removed.

65. **Mydriatic Action of Organ Extracts.**—Catapano describes experimental work which demonstrated that extracts of the suprarenals and hypophysis have a distinct and intense mydriatic action, while a weaker action was observed in the same line with extracts of the thymus, kidney, pancreas, liver, ovaries, testicles and muscle tissue, but not with the thyroid, brain or spleen. The mydriatic action is thus shown to be not an exclusive property of the suprarenals.

67. **Differentiation of Human and Cow's Milk.**—Tugendreich states that human milk gives a brown color reaction, while there is no reaction with cow's milk, when 3 c.c. of the milk are mixed with an equal amount of a 1 or 2 per cent. solution of silver nitrate and rapidly heated to boiling, three times in succession. He thinks this color reaction is connected with the

urine reaction mentioned by Engel and Turnau, whose article was abstracted in The Journal, February 18, page 546. [A later article by Boschan explains the reaction as merely the reduction of the silver nitrate by the chlorid in the urine. The brown stain occurs when the proportion of chlorids is low.]

68 *Varying Susceptibility to Opium with Age. E. Döbeli.

68. **Opium for Children.**—Döbeli reports extensive experimental research and clinical experiences which supplement the data in the literature, all proving that infants are especially susceptible to opium, but that older children are no more sensitive than adults if the dosage is proportional to their age. Suckling rabbits were twice as sensitive to opium and morphin as adult animals, but after the young rabbits had been eating ordinary food for a time they were no more sensitive than adults. He found, however, that the susceptibility to codein was alike at all ages.

71. **Salvarsan in Syphilis.**—Marschalko has never witnessed any serious signs of arsenic intoxication in the course of salvarsan treatment of almost 400 patients, but he warns that subcutaneous and intramuscular injections have no durable curative action. In fifty-four cases in which the patients have been under continued observation for from two to five months, recurrence has been the rule in nearly 50 per cent., and he advises other physicians not to waste their efforts with these ineffectual technics, but to use the intravenous technic which, he states, seems to be far more reliable in respect to the durable action of the drug. He ascribes great importance to the Wassermann reaction, having found it a most valuable guide in over 4,000 cases of syphilis in the last two and a half years. In most of the cases in which salvarsan was given the Wassermann reaction gradually declined in intensity, but it became absolutely negative in only a few. He thinks that salvarsan given by the intravenous route, supplemented by mercury, is the technic for the future. He refuses now to inject salvarsan when there is a tendency to paralysis, as one patient who had had paralysis for some years died two weeks after injection of 0.3 gm. of salvarsan. There seemed to be considerable improvement for ten days after the injection, but then severe paralysis developed; there were no symptoms of arsenic intoxication at any time.

72. **Technic for Intravenous Injection.**—The danger with intravenous injection is that the needle entering the vein may go too far and injure the posterior wall of the vein. To avoid this secondary injury, von Notthaft always exposes the vein, incises it between clamps and then cautiously introduces the needle in the incision. This technic cannot be applied casually in the office or home.

74. **Treatment of Lupus of Mucous Membranes.**—Senator states that expert examination of the mucosæ is indispensable for detection of all foci and lesions, and that surgical treatment will succeed while other methods are liable to fail. Long-continued supervision is necessary to attack recurrences at their first inception.

75. **Thyroid Intoxication After Iodin Medication.**—Wolfsohn reports the case of a woman of 42 who was given potassium iodid in treatment of leg ulcer, as the lack of benefit from other measures suggested a possible syphilitic factor in the lesion. The day after the iodid had been commenced, the patient complained of enlargement of the neck and malaise, with tremor of eyelids, tongue and fingers; the pulse increased to 128 and the heart-beat was unusually loud and fast, with slight enlargement to the left; there was no fever. The iodid was suspended at once and the symptoms had disappeared by the end of a week. Three months later, the leg ulcer showing no improvement, it was dressed with vioform, a powder containing iodin, and in half an hour the entire leg burned and itched and in the evening the neck had become enlarged and an erythema developed, with tremor; both lobes of the thyroid were found enlarged, but not tender. During the intervals and beforehand there had never been any signs to call attention to the thyroid. In another case a woman of 32, with an old tendency to goiter and nervousness, developed Basedow symptoms after a course of iodids and thyroid tablets. The injury from this treatment persisted unmodified after the suspension of this treatment and the exophthalmic goiter syndrome has continued a progressive course during the five years since. Injection of 5 c.c. of this patient's serum into a guinea-pig evidently induced a special hypersusceptibility to iodin in the animal as it died with signs of anaphylaxis when injected with a little iodin which the control animals bore without disturbance. Wolfsohn's experiences further warn of the necessity for constant supervision of patients taking iodin, whether there is a manifest goiter or the thyroid is not palpable. The possible injury from iodin cannot be estimated beforehand; even minimal amounts are liable to induce signs of severe thyroid intoxication.

79. **Picric-Acid Test for Seminal Fluid.**—Barberio here reviews all that has been published on this forensic test for differentiation of human seminal fluid, the general conclusions testifying to the sensitiveness and reliability of the test. An equal volume of a saturated aqueous solution of picric acid is mixed with the fluid to be examined, after filtration; the specific crystals soon form even in a concentrated solution of five-year-old fluid. The crystals dissolve if the mixture is heated, but after filtering they recrystallize out again as the fluid cools. The crystals are insoluble in cold water, but dissolve in dilute hydrochloric acid and in solutions of the halogen salts of the alkaline metals. The specific crystals are octahedrons, and the findings parallel those with the Florence test, but the reaction can be obtained for years after the Florence test has ceased to give positive findings.

80. **Diabetes Mellitus in Children.**—Langaker reports from Christiania the history of a healthy family with eight children, all apparently robust, until one after the other five of the children died between the ages of 4 and 11 of typical diabetes mellitus. The environment was good and the children well cared for, but five died thus in the course of nine years. Nothing grossly pathologic was found at the necropsy of the first child that died but in the last child the pancreas seemed to be much degenerated; the others were not examined post mortem.

89 Technic for Wassermann Reaction. A. Alexander.

83. **Acute Tuberculous Iritis After Chilling.**—The importance which industrial insurance is assuming in Germany lends interest to the case reported: A boy of 14 was driving a wagon through a small stream when the pole-pin broke and

he had to work breast-high in water for some time to remedy the trouble. A few days later he developed acute tuberculous iritis of the right eye, compelling enucleation. Signs of a slight apical process were detected with the Roentgen rays. Fleischer admits the possibility of the effects of the chilling mobilizing bacilli in the lungs and setting up an acute process in the eye, but he does not regard it as very probable. The lack of similar cases on record in the literature testifies against the etiologic importance of the chilling; otherwise such occurrences would be common.

84. **Differentiation of Exophthalmic Goiter.**—Kraus calls attention to sudden attacks of intense pain in the upper abdomen and to increased radiation of heat as signs of possibly latent exophthalmic goiter. The abdominal pain in two of the most typical of his fifty cases came on suddenly, resembling gall-stone colic or the crises of tabes, and was so intense that only large doses of morphin could control it. The celiac plexus was tender but not the gall-bladder region. The attacks did not correspond to intake of food; they came on generally at night and application of cold or heat gave no relief. The pain was ascribed at first to spasm of the abdominal vessels, and drugs to act on the kidneys were given but without effect. One patient also had the typical "giving way of the legs" sign of exophthalmic goiter but there was no paralysis; the extensors of the knees gave way completely all at once and the patient required aid to get up from the kneeling posture. The very severe acute condition in the other patient had evidently been aggravated by local application of iodin. After exclusion of all other causes for the pain, nothing was left but the assumption of action on the solar plexus of the toxin causing the exophthalmic goiter. In a third case, a man of 28 had suffered for seven years from mild exophthalmic goiter which was finally aggravated by overwork. Then attacks of pain came on in the night accompanied by vomiting. In a fourth case the spasmodic pain was the first symptom of trouble; a man of 52 was suddenly attacked with violent abdominal pain—neuralgia as he supposed. The pain persisted and he lost 21 pounds in weight in two weeks and by the end of the month his weight had dropped from 172 to 118 pounds. Several courses of sanatorium treatment brought no relief. By the end of three months symptoms of exophthalmic goiter developed, including restlessness insomnia, palpitations and pains in the shoulders, but the appetite remained good. On suspicion of "Basedowoid," he was given antithyroidin and the pains gradually subsided under this and hydrotherapy with application of the continued current to the neck. The Basedow triad since has become more pronounced but the general health has improved and there has been no recurrence of the abdominal pains. Another important sign of hyperfunctioning of the thyroid is the increased radiation of heat from the skin. The temperature in the axilla is liable to be as high as that in the mouth or even a trifle higher. The burning skin with otherwise latent exophthalmic goiter may suggest latent tuberculosis. Cardiovascular neuroses may simulate exophthalmic goiter but the lack of rapid drop of weight speaks against the latter. Hyperthyroidism may induce a condition resembling chlorosis, and during the menopause disturbances may develop suggesting the Basedow triad. This borderland disturbance deserves special attention, Kraus remarks, as the prevailing tendency to give iodids in prophylaxis or treatment of arteriosclerosis is liable to induce these nervous disturbances or aggravate a latent tendency to exophthalmic goiter. Another sign of hyperfunctioning of the thyroid is the tendency to frequent and copious stools. This sign is particularly instructive when individuals long constipated suddenly find bowel functioning becoming regular as other signs of hyperfunctioning on the part of the thyroid develop. In all dubious cases the scale is turned by the disproportion between an abundance of nourishing food and the progressive decline in the body weight.

100 Teaching of Pathology in the United States. H. Chiari.

90. **Salvarsan in Syphilis.**—Kopp was discouraged by the frequent local necrosis with subcutaneous injection, and he now uses the intravenous route exclusively. In his experience with 130 cases he had this necrosis in 20 per cent. of the subcutaneous cases, but has had no mishaps in the forty-eight patients treated by the intravenous route. In three cases the injection was made soon after infection, before the primary exanthem had developed, and none of the three patients has shown any sign of recurrence during the five months since, so that he regards them as probably cured.

Treupel and Levi have also changed to the intravenous route but warn that this method cannot be applied to outpatients. In one case they noticed total facial paralysis and considerable deafness after two injections of salvarsan, the symptoms resembling those reported by Finger in a few cases.

93. **The Diastolic Blood-Pressure and Palpation of the Ulnar Artery.**—Ehret has compared the findings with his method of palpation of the ulnar artery with those from auscultation, and with von Recklinghausen's method of oscillation. He says that with a simple Recklinghausen cuff, a rubber bulb and a manometer both the systolic and diastolic pressure can be determined by his method with as much precision as with a more expensive apparatus. He gives the conclusions from study of the findings on application of his method in over 1,000 cases.

94. **Stroganoff's Prophylactic Method of Treating Eclampsia.**—Roth reviews the experiences at the clinic in charge of Leopold at Dresden where Stroganoff's method was applied in fifty cases. The results were encouraging and justify, he declares, the adoption of this method in routine treatment of eclampsia in the home when removal to an institution is impracticable for any reason. The main point is to commence the treatment early and carry it through systematically according to Stroganoff's directions. [They were given in The Journal, July 3, 1909, page 86.]

95. **Rigidity of the Arteries in Children.**—Hamburger has frequently noticed unusual size and hardness of the arteries in children between the age of 8 and 14; the findings are sometimes so pronounced that they suggest arteriosclerosis or kidney disease, but he ascribes the phenomenon to nervous vasomotor influences. Certain signs of neurasthenia and nervous irritability can usually be detected in these children, and this exaggerated tonus of the artery is encountered during the years when school life makes special demands on the nervous system. Disturbances of this kind are more common in ambitious, studious children.

96. **Exercises in Repose.**—Hirschlaff has devised a system of exercises which aim to relax all the volitional muscles while excluding external impressions and promoting mental concentration. The patient reclines on a lounge, the eyes covered and the attention concentrated on his slow breathing. He has the patient do this for five respirations and repeat every hour or so during the day. A little perfume on the upper lips helps to concentrate the attention, and he describes other devices to promote absolute repose of the muscular and nervous systems in treatment of cramps and tics, professional neuroses, chorea, tremor, etc.

Therapeutische Monatshefte, Berlin

February, XXV, No. 2, pp. 81-144

101 *Treatment of Diabetic Acidosis. L. Lichtwitz.
102 *Albumin Milk in Infant Feeding. (Erfahrungen mit Eiweissmilch.) E. Welde.
103 Lime Metabolism in Connection with the Food. (Der Kalkstoffwechsel in seiner Abhängigkeit von der Nahrung.) M. Kochmann.
104 The Organism Does Not Become Accustomed to Action of Certain Narcotics. (Ueber die Gewöhnung an die Narkotika der Fettreihe.) F. Japhé.

101. **Substitutes for Sodium Bicarbonate in Acidosis.**—Lichtwitz discusses the mechanism of the acid intoxication in diabetes and shows that sodium salts with anions capable of combustion are preferable to the bicarbonate. Sodium citrate is advantageous as its taste permits it to be added to certain dishes or given with lemon juice as lemonade. It does not cause disturbance in the stomach like the bicarbonate; the appetite does not suffer, and he has never observed diarrhea even with 50 gm. (750 grains) a day. In a typical case 20 gm. a day of the bicarbonate caused diarrhea; it was then suspended and 30 gm. of the citrate given daily, which seemed to have an equally good effect on the metabolism while no further bowel trouble was noticed. The elimination of nitrogen also increased under the citrate. The citrate might be injected intravenously in emergencies; the bicarbonate is less adapted for this method of administration on account of its strong alkaline reaction. The citrate has only a weak alkaline reaction and this can be neutralized by adding a little citric acid.

102. **Casein Milk in Infant Feeding.**—Welde reports a year's experience with the Finkelstein and Meyer *Eiweissmilch*; it contains very little sugar and salts and proportionately large amounts of casein. He says that this albumin milk fulfilled all his anticipations and more, and may possibly prove the best substitute for mother's milk, at least during periods of indigestion accompanied with diarrhea. It has the disadvantages of a high price and uninviting aspect and taste. One new-born infant tested thrived on it; three infants with eczema were cured soon after being put on the albumin milk, twenty-three of twenty-five infants with severe indigestion were cured, as also sixteen in twenty in the phase of "decomposition," two of three infants with acute intoxications and six of eight with severe infectious processes. Only seven of the fifty-six very sick babies died, while among those saved were a number who had seemed to be actually moribund. Some of the children taking the "albumin milk" passed safely through an intercurrent influenza. This modification of milk was described in The Journal, July 2 and 30, 1910, pages 93 and 407.

108 Nature of Hysteria. O. Kohnstamm.
109 Anaphylaxis. (Wesen und die Bedeutung der Ueberempfindlichkeit.) E. Friedberger and F. Klemperer.

105. **Typhoid Fever in Children.**—Baginsky discusses the points in which typhoid in children differs from that disease in adults. He feeds the child milk, broth and raw yolks of eggs, with a little wine during the entire febrile stage and convalescence. He thinks the wine is important to keep up the general nutrition. He warns in particular to be on the watch for otitis. The child's heart can be depended on much more than the heart of the adult, and drugs are seldom necessary for disturbances in the heart action, but too much attention cannot be paid to prevention of boils and other disorders of the skin as secondary septic infection may have most serious results.

106. **Febrile Liver Syphilis.**—Huber describes a case in which a man of 31, four years after infection with syphilis followed by energetic mercurial treatment, had violent attacks of pain in the liver radiating to the right shoulder; the liver was much enlarged and after two years and a half fever developed with night sweats and chills. Gall-stones had been diagnosed; no improvement followed systematic medical treatment on this assumption and an operation for the supposed gall-stones followed. None was found but signs of gumma of the liver were discovered; under a single injection of salvarsan the entire syndrome subsided. Tertiary syphilitic liver fever is of the hectic type, intermittent or remittent, with night sweats and more or less pronounced chills. With all this the general health suffers little for a long time. The absence of jaundice is also suggestive.

February 2, XXIV, No. 5, pp. 153-190

110 *Changes in the Pancreas in Diabetes Mellitus. A. Weichselbaum.
111 Behavior of Albuminuria and Tube-Casts in Urine During a Course of Mineral Waters at Marienbad. K. Zörkendörfer.
112 Leg Phenomenon in Hysteria. (Ein dem "Beinphänomen" der echten Tetanie in seinem klinischen Aussehen gleichendes, vielleicht richtiger als "Pseudo-Beinphänomen" zu bezeichnendes Symptom in einem Falle von Pseudo-tetania hysterica.) W. Buettner.
113 Globulins in Syphilitic Serums. (Vergleichende Globulinmessungen an luetischen Seris.) R. Müller and W. Hough.
114 Metaplasia of Gastric Epithelium. A. Hermann.

110. **The Pancreas in Diabetes.**—Weichselbaum found the islands of Langerhans strikingly pathologic in the 183 cadavers of diabetics he has had opportunity to examine, while no changes of the kind in the islands could be detected in the seventy-three cases of chronic tuberculosis he examined post mortem. He states further that his findings demonstrate that it is not any special changes in the islands but the extent of involvement which determines the development of diabetes. In some non-diabetics the parenchyma was found atrophied while the islands were not much degenerated; in a few cases the pancreas weighed less than 35 gm. or even 20 gm. but the islands had maintained their integrity; although the urine had been examined repeatedly for sugar during life the findings were constantly negative. The type of the diabetes corresponds to the different forms of the changes in the islands, the graver forms accompanying complicating arteriosclerotic changes in the islands. The practical conclusion is that everything that tends to favor arteriosclerosis should be carefully avoided when diabetes is feared or is established. Chronic alcoholism is a factor of this kind; it seems to be able to induce not only cirrhosis of the liver but a chronic interstitial pancreatitis which may lead to sclerosis of the islands.

Zentralblatt für Chirurgie, Leipsic

February 4, XXXVIII, No. 5, pp. 153-184

115 *Opening New Collateral Blood and Lymph Routes. (Eröffnung neuer Abfuhrwege bei Stauung in Bauch und unteren Extremitäten.) O. Lanz.
116 *Urethral Injection of Glycerin to Facilitate Passage of Sounds. (Perurethrale Glyzerin-Druckinjektion zwecks leichteren Entrierens sog. impermeabler Strikturen.) T. Goldenberg.
117 *Improved Technic for Nephropexy. Liek.

115. **Operative Opening of New Collateral Circulation.**—Lanz has applied the Talma operation in four cases of ascites from cirrhosis of the liver, with complete success in two cases and absolute failure in the others. In a more recent case the patient was a man of 69 with enormous ascites and suspected cirrhosis of the liver and alcoholism. The absence of enlarged veins in the abdominal wall and the age of the patient suggested carcinomatous peritonitis. In order to divert the fluid into a new route, after removal of 12 or 15 liters of fluid, Lanz drew the right testicle upward out of the scrotum by pulling on the spermatic cord, and implanted it in the open abdominal cavity, suturing the spermatic cord its entire length around the peritoneal incision. The discovery of tuberculous nodules in the peritoneum had left little hope of permanent recovery and the patient died five weeks later. There had been no recurrence of the ascites but the spermatic cord and the retroperitoneal tissue were found gorged with serous infiltration, everything showing that the operation had provided a collateral circulation for the lymph with direct drainage of the peritoneal cavity along the spermatic cord with its wealth of lymphatics. The outcome might have been still better if the testicle had been wrapped in omentum. The findings at necropsy corroborated the advantages of this method of internal drainage; the results are more promising, Lanz declares, than when the omentum is merely fastened—as by the Talma operation—to the abdominal wall which is not so rich in lymphatics.

116. **Glycerin for Impermeable Urethral Stricture.**—Goldenberg injects about 20 c.c. of glycerin under considerable pressure and at once the catheter finds its way through the previously impermeable stricture. The glycerin has the further advantage of being completely soluble in water, thus obviating all danger of embolism.

117. **Nephropexy.**—Liek used the capsule of the kidney to fasten it in its proper place in a case reported, drawing the slit capsule up around the lower pole of the kidney and fastening it to the twelfth rib. The technic is illustrated.

Zentralblatt für Gynäkologie, Leipsic

January 23, No. 4, pp. 85-112

127 Pathogenesis of Infectious Purpura Hemorrhagica. S. Cannata.

124. **Inherited Hemorrhagic Telangiectasia.**—Osler reports a fifth case of this anomaly, his other four having been published at various times since 1901. Others have reported similar cases since so that he now knows of fourteen or fifteen families in which two or more members through from two to five generations had these multiple telangiectasias of the skin and mucous membranes, bleeding frequently and leading in some cases to repeated and almost fatal epistaxis. The only etiologic factor of any account seems to be the heredity. One of his patients had had repeated epistaxis for over forty years; another had frequent hemorrhages from a vascular nevus on the hand and another on the arm. Probably in many of the cases the anomaly has been regarded as a manifestation of hemophilia, but this is incorrect, he thinks. The trouble is a dilatation of the capillaries and smaller veins and much can be done in treatment by cauterization. In his last case he warded off danger by destroying the dilated vessels in the nose and on the tongue by cauterization. The patient was a woman of 35 and the lesions had notably increased in number and size during the last six years. Coe has reported benefit from administration of calcium lactate in such cases, and Osler suggests that if the angiomas are large it might be wise to apply radium treatment.

125. **Exploratory Puncture of Bone Marrow.**—Ghedini here reports the experiences on which he based his conclusions recently summarized in these columns, February 4, page 389. Application of the measure in twenty-four cases has demonstrated, he remarks, the ease and simplicity of the technic and its harmlessness.

Hospitalstidende, Copenhagen

February 1, LIV, No. 5, pp. 105-136

128 *Multiple Punctures in Treatment of Cystic Disease of the Kidney. (Behandling af det multilokulære Nyrekystom med multiple Punkturer.) T. Rovsing.
129 Inherited Predisposition to Pulmonary Tuberculosis. (Arvelighed af Disposition til Lungetuberkulose.) N. J. Strandgaard. Commenced in No. 4.

128. **Multiple Puncture in Cystic Disease of the Kidney.**—Rovsing had a patient, a man of 41, who had been healthy until about a year before when violent pains in the left kidney region came on suddenly and the attacks returned from time to time, with occasionally mild pains in the right side. There was considerable albuminuria and the left kidney was found much enlarged. On the diagnosis of tumor of the kidney. Rovsing exposed the left kidney and found it studded with cysts. Nephrectomy was contra-indicated as cystic disease is generally bilateral, and the urine from the other kidney was not normal. He at once punctured the superficial cysts and then the deeper and deepest ones. There was scarcely any bleeding and after the puncture the kidney subsided to less than half its former size. He left a wick in the wound and the diuresis increased while the albuminuria disappeared. The patient was freed entirely from pain and regained full earning capacity, dying three years later from uremia following an acute febrile disease. Rovsing had been very dubious in regard to the outcome, for, if the "retention cyst" theory of cystic disease of the kidney is correct, the multiple puncture holes would have drained away the urine and infiltration and a fistula would have been the result. On the other hand, if the disease were in the nature of a new growth, there was danger that the tumor mass would proliferate into the adjoining tissue. Nothing of the kind occurred; the wound healed rapidly and there was no question but that the operation was not only palliative but improved the kidney functioning; there must have been considerable sound kidney tissue which was able to resume functioning when released from compression by the cysts. Encouraged by this success he applied the same measure in two other cases later, with equal benefit, as he relates in detail.

THE INTERPRETATION OF PAIN AND THE DYSESTHESIAS

CHARLES L. DANA, M.D., LL.D.
Professor of Nervous Diseases, Cornell University Medical College
NEW YORK

In one of Horace's Epistles, he speaks of an *ægrimonia fastidiosa,* an expression which indicates an illness characterized by certain niceties of suffering, and not by the common and every-day variety of pain.

It is to this field of what may be called fastidious, though not unreal, distress that I invite some attention now; and my excuse is, that I believe it greatly deserves and will amply repay serious study and patient attention. For the time has come for the physician to study the subjective side of his patient more carefully, and the psychology of suffering in general, so that he can learn and interpret the patient's state of mind, as thoroughly as he does that of the body.

The research into human ailments by present methods has nearly reached its limit so far as clinical study goes. It must be continued in the laboratories, and from the methods of the laboratory we may yet expect our richest finds. A field most fertile for the neurologist now is that of studying the mental make-up of his patient, his habits of thought and feeling, the quality of his reactions and the mold in which education and environment have shaped his character. Then we begin to understand what he means by his complaints. The elements of psychology, when properly taught, do not form a difficult subject, or one which medical students cannot easily master. I can heartily second the advice recently given by President Schurman of Cornell, that this branch be taught to the medical student as an obligatory part of his course. So far, it is only the psychiatrists who have seriously taken up and applied psychology to medicine; but by doing so they have given to that branch the enormous impulse which it has received during the last decade. Neurology will fall behind if it does not make use of the same instrument.

THE DOCTRINE OF PARALLELISM

Let me now apply this preaching and come to the subject in hand. Psychology has shown that all mental activities are accompanied by neural activities, and that there is such a thorough-going parallelism between the two that when the mental state is disordered the accompanying neural activity must be also disordered. As Mr. Marshall puts it, "All neurotic activity is but an emphasis of a corresponding neururgic activity."[1]

We cannot imagine for example, a hallucination (which is an abnormal mental state) to be the production or the parallel of a perfectly normal neural state, or that there can be a perfectly normal neural activity of any kind running parallel with a morbid mental activity.

We cannot, as psychologists, imagine an agonizing pain disturbing our consciousness, without supposing *that there is an abnormal neural state associated with* it. Thus it must be that all pains and all suffering are real things. There is no such thing, strictly speaking, as an imaginary pain; that is, a pain which has no morbid neural condition underlying it. There is, furthermore, no such thing as a purely mental disease, for all disturbances of the mind are associated with some abnormal neural change. I assert, therefore, that whenever a person believes that he is suffering, he really is suffering. There are no functional psychoses and no functional neuroses. I emphasize this point, because *it is so easy and so common a thing* for physicians to dismiss a certain class of patients by saying: "There is nothing the matter with you; forget it and you will be well." The view of human suffering which I take is directly the opposite of that of the late esteemed Mrs. Eddy, but I must bear the obloquy. The surgical method of treating hysteria is to say: "You are a damned fool; go and behave yourself." Sometimes this form of therapeutic procedure answers, but it is not because the statement is strictly true that it succeeds. The fact that there is a system of therapeutics, based on the view that pain or morbidly unpleasant sensations do not exist, is not a proof of its veracity, even though the theory may often answer well. Pains *do disappear when the attention is directed elsewhere,* and the threshold of consciousness is raised so that the disagreeable sensations are excluded; but there was all the same an abnormal condition, cured by opposing to it a mental state; just as by changing the gait, certain strains are removed and ease of walking returns.

This paper is an attempt to study pains and dysesthesias and to show what they mean and how serious they are. I shall say little about the ordinary pains due to lesions of the peripheral and spinal sensory tracts; the facts here do not need much further interpretation.

SENSORY TRACT PAINS

We have a rather different kind of pain according to the seat of the irritation in the sensory nerve-tract.

1. For example, lesions of the cutaneous terminals of sensory nerves, such as occur in diabetic neuritis and certain forms of toxic and arteriosclerotic neuritis, cause symptoms more of the nature of paresthesias, burning sensations and soreness, than of actual pain.

2. Lesions of the muscular and visceral sensory terminals cause colicky, anginal and cramping pains.

3. On the other hand, lesions of the nerve-trunks themselves, as in alcoholic or rheumatic neuritis, cause a distinct aching and throbbing kind of pain, with occa-

---

[1] Marshall, Henry Rutgers: Consciousness, Macmillan Co., 1910

sional shooting pain running more or less along the nerves, with the complicating feelings of heaviness, weakness and some minor paresthesias.

4. Lesions of the posterior ganglia and sensory roots cause sharp, shooting pains more particularly, together with vasomotor disturbances.

5. Lesions of the sensory tracts of the cord and brain, (aside from the thalamus) rarely cause pain; more often only numbness and other paresthesias, such as cold and hot sensations.

6. Lesions of the thalamus cause burning, smarting pains.

7. Lesions of the sensory cortex of the brain cause no pain.

Of course the character of pain depends much on the nature, intensity and duration of the stimulus, but the general facts are about as I have stated.

Now, in clinical examinations, it is usually quite easy to interpret the description of the pains complained of and to determine that they are caused by some irritation of a nerve terminal as in diabetic neuritis, or of the trunk, as in brachial neuritis, or of a posterior ganglion and root, as in tabes and tumors of the cord.

PSYCHIC AND ATTENTION PAINS

But there is another group of sensory complaints. For ten or fifteen years, it has been my custom when a patient was particularly eloquent and emphatic in the description of various painful symptoms, to write down the characteristics on a slip of paper, add to it the name, age and diagnosis and file away the semeiologic note. I have collected these multitudinous scraps of sensorial description and have tried to associate them with some definite group of nervous or mental ailments. I have not been able entirely to clear up the mystery of bizarre complaints by this plan, but I have got thus far, namely, that now when certain groups of sensory symptoms are told me, I can often infer at once that the patient has one or another form of a psychoneurosis, or has some degree of arteriosclerosis, or of toxic or neuritic irritation.

There are two tendencies among those studying the psychoneuroses just now. One is to group what we may call the minor psychoses into three or four classes; and to put our patients into Class A, B, C, or D, and then treat each as we would the similar patients of this class. Other psychoneurologists advocate the individual treatment of patients, and deny the importance of making any very definite diagnosis. Each individual and disease-condition, they say, should be treated by himself and itself. The past history is unfolded to the last detail, the present state is analyzed and the disordered associations are then treated and educated into right channels again.

The true method lies probably in the golden mean, but my habit and practice, I confess, go more with the first group. It seems to me that there are three or four broad general lines in which chronic forms of psychoneuroses shape themselves, and that nearly all cases can, with proper caution, be merged into one or other of these groups.

There is, for example, a certain condition which is known as neurasthenia, in which the cerebral and spinal centers are weak and irritable and easily exhausted and tired. In these cases, there is sometimes no important psychic defect.

There is another group which has received the name of psychasthenia, in which there is always present some psychic defect. The dominant and important symptoms are mental, and the patient has fears and doubts, tormenting ideas, depression and panics. Belonging to this group are those persons also who are subject to hysterical crises and to the impulsions and explosions characteristic of the inebriate.

There are, again, forms of mild depression which usually in early life are not accompanied with any nervous or physical symptoms, but in later life are very closely associated with physical symptoms. These depressions are for practical purposes called the manic depressive type and involution type of melancholia.

Finally, there is a condition of constitutional inferiority in which the individual has always an undue sensitiveness to irritation.

In looking over my Pandora's box of woe, I find that a rather distinct kind of pain and dysesthesia goes more or less with each of these groups.

THE PAINS OF THE OBSESSIVES

In interpreting the tales of suffering and pains which are unfolded to us, by persons who have no grave organic disease, one has to note carefully the attitude of mind of the patient towards his own suffering. In a certain class of patients, the pains are described with enthusiasm and intensity of feeling—with, indeed, a sort of joyful emphasis—the sufferers using a most rich vocabulary of superlatives as they point out their woes. The patient, with a smile, says that she is suffering untold and infinite agony from a pain which has not left her arm or head or back for six months. Another, with a certain expression of satisfaction, says that she has had a headache for fourteen years, always very severe. Another describes in a tumultuous flow of words a succession of curious and unpleasant sensations for which we have no definite names in our clinical symptomatology.

These patients, who with a healthy look and a somewhat earnest and satisfied way describe their sufferings, always belong in general to the class of obsessives or psychasthenics. Their pains are generally pretty definite. It is always a neuralgia of the arm or a pain over the kidney or the liver, or a steady pain in the back or on the side of the head.

The symptoms are those which involve especially the epicritic nerves; in other words, they are clear-cut, severe pains, or definitely outlined and located feelings of heat, cold, or tactile dysesthesias.

The localization of these pains is usually in some spot that does not correspond with the course of a nerve or with any nerve plexus. They are in the shoulder, or a joint, or the side of the head or back. Very often they lie in or over the abdominal viscera, and include neuralgias or paresthesias of the rectum, stomach, intestines or uterus. As a rule, these pains have no doubt been originally started by some definite sensory irritation, such as an injury or a disturbance of visceral function, or a strain put on the eyes or brain. In the obsessive patients, there is usually also an undercurrent of neurasthenia, and their pains, brought on at first by exhaustion and toxic conditions, are emphasized and glorified by the psychasthenic condition.[2]

---

[2] Psychasthenic and Neurasthenic Pains.—The following are from notes of cases: a favorite sore spot on the side of the head; a tremulous jelly-like feeling in the back; a pain in the ovary, when excited; a painful globus; a localized paresthesia over the supraclavicular and infraclavicular region, lasting several years; a dysesthesia fixed definitely in the knees, elbows and epigastrium; fixed pains in side of head, in side of chest, in arm, fingers, ovaries; pressure, soreness and heat of occiput, tightness around jaw or neck; helmet sensation, sensation of the head being a vacuum; of the body being too short or too long; sensations of nervousness, tensic [illegible] ty, restlessness, inside trembling, sinkii [illegible] int, or die; sensations of unsteadiness, [illegible] eme painful sensory reaction to certain [illegible], developing pains, nausea, faintness, vertigo, etc.

The pains of the obsessives are such as can be argued with. They will admit that they should not have these pains, that perhaps they are imaginary, though they do not really believe it; they will often try conscientiously to forget them. And by suggestion, by earnest explanation, by various therapeutic incantations or by long and patient reeducation, often excellent results are produced.

A healthy woman about 40 years of age was met one day by her son, who had returned after a long absence and who grasped and squeezed her hand with an extra degree of filial earnestness, so that he practically crushed some few peripheral nerve filaments of the hand and caused her great pain. This lasted throughout the day; the next day, instead of subsiding, it increased. The hand was bandaged and kept at rest, but the pain still continued, and after some weeks was so severe that it was determined there was a neuritis. This neuritis, it was supposed, ascended, so that in the course of the next nine months, the several nerves of the arm were cut, three different operations being done on it, all without relief, and with the result of still greater suffering. At the end of the nine months I examined the hand and found nothing objectively wrong, except what had been done by the surgeons. On my telling her to let her hand alone and go about her work, the pain in the course of a few weeks subsided, and she recovered the use of her hand.

In this case, the pains from which the woman had suffered for nearly a year were not due to any irritation of importance in the sensory tracts. The pain was central and would ordinarily be called "imaginary" or hallucinatory.

The psychology of it is not so simple. It means that there was a disorder of attention and a lowering of the threshold of consciousness; all the time there was some real neural irritation which occupied and morbidly enlarged the field of attention. It is not necessary to invoke hysteria or necessarily the subconsciousness or the memory of the painful squeeze tucked away in the optic thalamus. The term "attention-pains" offers a sufficient psychology to begin with. With these pains is usually an egotistic and anxious feeling, and these factors furnish the indications for treatment.

A patient of mine, now a man of 60, has for fifteen years been going around on crutches because he has so much pain in the knees. These knee-pains are always present slightly, but are greatly increased by walking, or by any serious vibration; so that he cannot use a motor car or carriage, and he travels, whenever it is possible, by boat. This patient is an educated and intelligent man, without any observable psychosis or stigma of hysteria, so called. The most elaborate methods of physical and clinical exploration have failed to discover anything wrong with his knees. He intelligently appreciates the explanation that his trouble is purely an idea and tries to follow the suggestion based on this line, without avail. For he gave up business and devoted his attention to his knees. Naturally he has attention-pains.

A woman aged 40, of good general health, came to me complaining of pain over the region of the liver, which she had had for nearly three years continuously. It was a kind of pain which would be associated with some disturbance of the gall-bladder. She had been examined in every possible way by the best experts, who all reached the conclusion that it was, as they termed it, "nervous." She had nothing to gain by having the pain, and seemed earnestly to try to raise herself above it. She and a devoted husband worked together daily over the pain, but it continued obstinately despite every kind of cure, until the time when I saw her. It then gradually disappeared under a course of educational therapeutics which was given to her. Her pain began from an acute local disturbance. It kept up through her attentions to it.

These examples illustrate some of the types of attention-pains which often baffle us.

The use of the word "hysterical," much used in this connection, conveys a very vague explanation to serious minds, and arouses generally indignant protest from the patients, who know perfectly well that the pains are not hysterical, or as they interpret it, "imaginary." And in fact the worst and crudest method of interpreting them is to say with finality that they are imaginary or hysterical. I will admit, however, that just as fetich-worship suits the savage, so the theory of a hysteria or the philosophy of mental science may sometimes answer for the ignorant.

NEURASTHENIC PAINS

There is such a condition as neurasthenia or nervous exhaustion, but it quite rarely exists by itself. It has certain painful symptoms connected with it which are real and due, it is to be supposed, to tired nerves, which means often persisting autotoxemia. The pains of the neurasthenics and of the constitutionally inferior are mainly headaches, occipital and frontal, and are associated with sensations of pressure and constriction or fulness and discomfort about the head. Pains along the back, such as occur in spinal irritation, are largely due to the condition of the muscle mass which supports the spine. There are also direct and reflex symptoms that come from tired hearts and stomachs and lazy intestines. These pains are described in a rational way, as a rule, and are usually recognized by the fact that they are increased by exertion, and lessened by rest.

The pains of neurasthenia, however, are apt to become associated with the attention pains, and an obsessive state sometimes develops on a neurasthenia.

DEPRESSION PAINS

The attitude of the morbidly depressed patient, who has pains, and especially of those who have that form of depression associated with anxiety, a malady allied closely to the melancholia of involution, is quite different, and the description of pains and suffering is given in more serious style. The patient says with shut jaw and serious look that he has not ceased to have pains in his knees for fifteen years; he has not slept for weeks; he has sensations of prickling, boiling, bursting, coldness and heat along the spine and knees which annoy him to a point beyond endurance. He says this with a weary, anxious look; the tears come to his eyes. His pains are more than real; they are frightening and agonizing.

No amount of reasoning has much effect on these patients, except for an hour or for the moment, for these sufferings are deep-seated and a part of their conscious life. They show you their hands, which seem to them hot or badly nourished and ask you to feel of them; they want you to examine the disturbed area and feel or see that there is something wrong in the tingling forearms, the drawing sensations about the knees, or the pulling sensations about the neck.

These are the patients who have the most curious and bizarre kinds of sensory complexes. One will tell you that he feels as though his legs were bursting, or as though his body was stuffed with pricking burrs. He has sensations about the head, not merely of pressure and constriction, but of some substance under the skin which is twisting or jumping or crawling. He has curious visceral pains, such as "boiling in the stomach" and feelings of heat deeply seated within the trunk, or within the limbs. He has sensations of coldness as though there was a piece of ice on the back, or of heat like a band over the chest, or of prickling irritation over the shoulders or in the knees.[3]

The general character of these sensations would make one think that in the dysesthesias of melancholia, the protopathic nerves are especially affected, while in psychasthenic pains, it seems to be more the epicritic nerves—sensations of a finer quality and more definite character.

When the patient comes to the physician's office, and begins to say that he has hot and annoying sensations in the knees and burning irritation along the back, disagreeable and rather indefinite disturbances of sensation about the hands and feet; when he begins to show you his limbs and point out the places where he suffers, one can infer at once that he is dealing with a person who has a hypochondriacal depression.[4]

By carefully recording the descriptions of symptoms given by patients, one can after a few interviews construct a sensory syndrome. If this is once done and attached to the history, it saves much trouble, time and repetition. Besides, when the patient knows you have all his troubles typewritten, he ceases to talk so much about them, and it does him good, for he knows that he has had a complete mental catharsis.

If one were to interpret these sensations psychologically according to the scheme which is presented below, I should say that in the psychasthenic pains there has ceased to be any peripheral irritation. The neuritis is gone; the nerve injury is healed, and the only neural disturbance is a morbid change in some primary sensory center, like the optic thalamus, where sensory impressions are first received and distributed. In other words, there is slight or no disorder of the sensory nerves, but there is some disassociation and disorganization in the work of the higher sensory mechanism. But beyond this there has occurred disorder of attention; the patient's mind has become so fixed on this slight neural change that the threshold of consciousness is greatly lowered; and even slight neural disturbance keeps up an agonizing suffering. I would still insist that there is a neural change, and that the pains are not imaginary, but the neural disturbance is always a minimum, while the focusing of attention on it is at a very morbid height. This may be shown in the diagram (Fig. 1 at A). It means, of course, that in these cases the therapeutic attempt should be directed toward turning away the field of thought to other channels and reestablishing the proper associations.

On the other hand, in the pains and dysesthesias that go with the anxious depressions, there is probably present a real morbid condition affecting perhaps especially the protopathic nerves. These usually do not arouse sensations in consciousness, but through conditions of autotoxemia, arteriosclerosis and the rheumatic and bad metabolic conditions, that usually accompany the period of involution, these nerves are irritated.

In addition to this the mind of the patient is depressed by his psychosis and made more sensitive and attentive to the inflow of sensory impulses. There is then both an increase in the stimulus and a lowering of the threshold of consciousness. These pains of the anxious depressives have a certain physical basis in the badly nourished and irritable nerves, and the alertness of self-attention which exists in anxious minds.

So we find that, in these cases, there is not much to be accomplished by attempting to divert the attention of the patients by therapeutic talks. They are relieved most by measures which improve the bodily condition—by rest, diet, fresh air and eliminatives.[5]

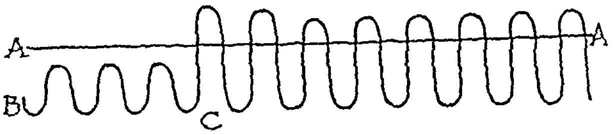

Fig. 1.—Diagram illustrating the conditions when a painful stimulus continues causing constant real pain. A, threshold of consciousness; B, waves of sensory stimuli; C, waves of abnormal and painful stimuli rising into consciousness.

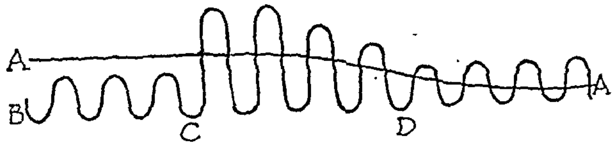

Fig. 2.—Diagram illustrating habit or attention pains. A, threshold of consciousness; B, waves of normal sensory stimuli; C, waves of abnormal sensory stimuli from trauma, inflammation, etc. At D the sensory stimuli have dropped to normal, but the threshold of consciousness has been lowered so that ordinary stimuli are felt as painful.

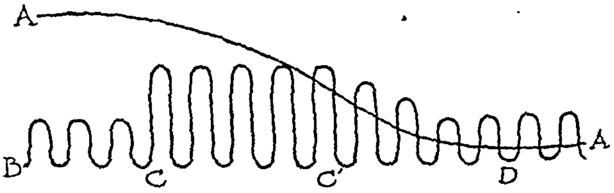

Fig. 3.—Diagram illustrating post-traumatic pains. A, B, and C, as in other diagrams. At C^1 the painful stimuli begin to cease, but the attention keeps the threshold of consciousness abnormally low and pain continues to be felt.

THE PSYCHOLOGY OF FUNCTIONAL PAINS

The accompanying diagrams and parts of the description have been prepared for me through the courtesy of Mr. Marshall.

The word "consciousness" is used in two ways: First, as an equivalent of *psychic existence as such*, as when we question whether the plants have consciousness, or say that stones have no consciousness; second, as the equivalent of *awareness*, which is a narrow phase of psychic existence as such. Thus, when one forgets, one is likely to say that he is not conscious that he did so and so.

---

[3] Depression Pains.—The following are actual descriptions given by different patients: feeling as if a piece of ice was between the shoulders with paresthesia and stiffness of neck; cold sensation in small of back as if it had shrunk up; burning *pain on top of head*; burning pain in the back; sensations of coldness of certain parts of the body; sense of heat and fever over chest and neck and head; sensations of burning, smarting like bee-stings over head, arms and back; sensations of body being filled and stuffed with pricking burrs; a feeling as if fine needles were sticking out of the scalp, or as if something were working and wriggling under the scalp; a feeling as if a ton-weight were pressing on the top of the head; hot hands and feet; dysesthesias of legs, arms and epigastrium; pricking over sides of chest and top of head, which becomes actual pain when worried.

[4] The custom of internists is to ascribe them to arteriosclerosis, a custom not founded on sound data.

[5] There has been a great deal said and written about the pains and dysesthesias of arteriosclerosis and of the gouty and arthritic states. Many symptoms, such as cold sensations, heat sensations, numbness and paresthesias of the hands and feet, are due in part at least to those causes. The burning feet and hand in diabetes and peripheral neuritis must be recognized, the dysesthesias (very rare) in central lesions, must be considered. But in these there is lacking the peculiar mental state. As for arterial sclerosis, one sees it repeatedly in the most intense degrees without the patient complaining of those sensory syndromes which go with neurasthenic, obsessive and depression states; hence, I do not accept the explanation commonly given of arteriosclerosis as a cause of the many pains and dysesthesias complained of by people who really have such vascular condition; the psychic factor is the important and real one.

The term "threshold of consciousness" is in common use. It indicates that there is a something below this so-called threshold. What we really mean is that we have a threshold of awareness within our psychic existence. All that is within the consciousness of any moment and that is below the threshold of awareness is part of what Marshall calls subattentive consciousness, and is what is generally called the subconscious. There are many different thresholds of awareness, and these thresholds shift sometimes suddenly. Such a shifting takes place when we wake up. If we represent the threshold of consciousness in any moment by an approximately straight line, then we may represent special mental items by waves as in Figure 1; the rise of each wave above the level of the threshold indicating the degree of its emphasis.

We suppose now, in Figure 2, the normal waves of stimuli are abnormally increased at C by some injury or inflammation. The waves of stimuli pass up above the threshold of consciousness and pain is felt. After a time the injury is healed and only normal sensory stimuli are propagated, but, the attention of the patient being directed to these stimuli, the threshold of consciousness is lowered and the pain is still felt. We have now the psychic, or attention or habit pains.

Figure 3 illustrates a somewhat similar condition. In the heat of battle or excitement of accident, the threshold of consciousness is greatly raised, *quoad* the sensory stimuli from an injured part. No pain is felt until later, when quieter and more normal conditions are brought about. Then at C^1 the real pains begin to be felt. They excite the attention of the patient and the threshold of consciousness is lowered at D and pains continue to be felt even when the injured part is healed. These are the pains of the traumatic psychoses.

SUMMARY

A more careful study should be made of the psychology of patients who complain of chronic pains and dysesthesias not due to objective causes. The study of elementary psychology in the medical schools should be obligatory. Clinical neurology will not make much further progress without psychology.

I have collected and analyzed the symptoms of pains and dysesthesias not directly due to organic disease, and have here tried to group them according to the neurosis or psychosis.

1. I find a certain kind of pains characteristic of simple neurasthenia.
2. Also pains, etc., of psychasthenia and the obsessives are peculiar to that psychosis. These perhaps involve especially the epicritic nerves. The mental attitude and reactions of the patient have to be considered. The pains of the traumatic psychoses mostly belong in this class.
3. The pains of the anxious and involutional depressions are especially numerous, bizarre and characteristic. They form for each patient a sensory-complex, and they seem especially to involve the protopathic nerves.

I interpret the symptoms of pains, etc., in terms of the psychology of Marshall. These are not imaginary pains, because there is a thoroughgoing parallelism between mind and body and there can be no morbid mental change without a corresponding neural change. Psychic pains are called "attention-pains," and the overemphasis in activity of minor psychic symptoms is invoked to explain their existence. There is not yet any simple test by which we can tell surely when a pain is not a real, but an attention or habit pain. A thorough study of the psyche and soma of each patient and a knowledge of the characteristic pains in the various groups will clear up most cases.

MIGRATION BY AMEBOID MOVEMENT OF SARCOMA CELLS GROWING IN VITRO

AND ITS BEARING ON THE PROBLEM OF THE SPREAD OF MALIGNANT GROWTHS IN THE BODY[*]

R. A. LAMBERT, M.D., AND FREDERIC M. HANES, M.D.
NEW YORK

It is the object of this note to describe certain ameboid phenomena observed in the cells of rat and mouse sarcomas when cultivated *in vitro*, and to suggest that these phenomena probably play an important part in the infiltrative and metastatic growth of tumors.

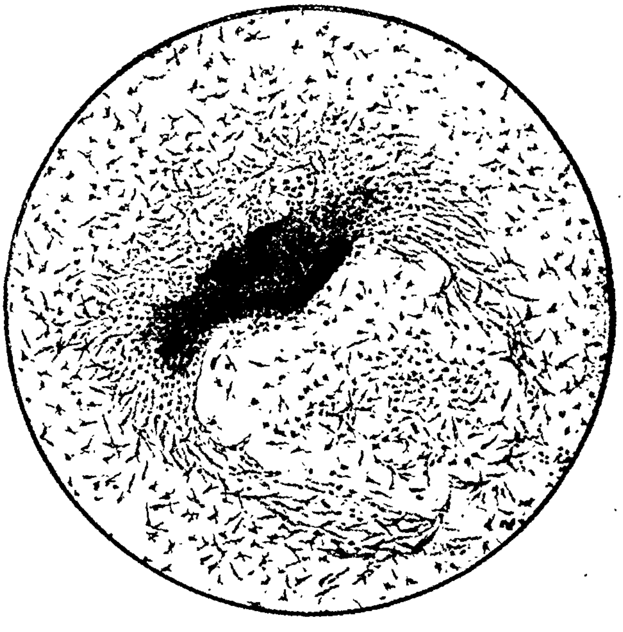

Fig. 1.—The edges of the sarcomatous tissue are beset with long, projecting sarcoma cells, and the adjacent plasma contains many isolated cells with remarkably irregular outlines.

We have employed in this study Burrows'[1] modification of Harrison's[2] technic, as applied by us[3] to rats and mice.

Since rat and mouse sarcomas do not differ essentially from one another in their behavior when cultivated *in vitro*, we shall confine our description, for the sake of clearness, to the various changes observed in the cells of a mouse sarcoma growing in mouse plasma. The edges of a freshly implanted piece of tissue, examined under the microscope, are sharply defined and free from projecting cells. The tissue itself looks compact and homogeneous. Twelve hours later the edges of the tissue are beset with long, projecting cells, and the adjacent plasma contains many isolated cells with remarkably irregular outlines (Fig. 1). The original piece of tissue is no longer uniformly dense and compact, but has become thinner and more translucent. The number of cells in the surrounding plasma increases now, from *hour to hour,* largely at the expense of the original tissue, which gradually grows thinner, until at from thirty-six to forty-eight hours, its volume has decreased to one-half or one-third its initial size. Indeed, the original mass of tissue may become resolved completely into its component cells, which pass into the plasma. Mitoses are seen, both in the original piece of tissue, and in the cells which have migrated from it.

3. Lambert and Hanes: Growth in Vitro of the Transplantable Sarcomas of Rats and Mice, THE JOURNAL A. M. A., Jan. 7, 1911, p 33.

The exact mechanism of this migration of sarcoma cells is observable with ease under the higher powers of the microscope. They pass from the tissue to the plasma by ameboid movement. Pseudopods are thrown out on all sides, and these increase or decrease in size in characteristic ameboid fashion (Fig. 2). The ameba itself scarcely furnishes more exquisite figures than do sarcoma cells. There is one difference however; the movements of amebas are much more rapid and active. This may be due to the rather firm consistency of the coagulated plasma in which the sarcoma cells are living. Fat granules appear very early, and it is quite interesting to watch them stream into a newly formed pseudopod. One is reminded forcefully of the movements of erythrocytes and other inclusions in the cytoplasm of the *Entamœba histolytica.* If a specimen showing active ameboid movements of the cells is removed from the warm chamber, and examined under a microscope at room temperature, the majority of the cells retract their pseudopods and become spherical.

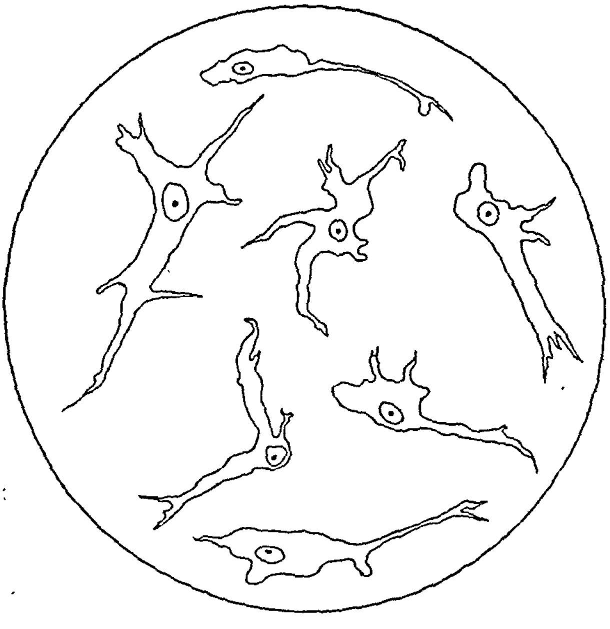

Fig. 2.—The sarcoma cells migrate from the tissue to the plasma by ameboid movement. Pseudopods are thrown out on all sides in characteristic fashion.

The phenomenon of ameboid migration of sarcoma cells growing *in vitro,* seems to us readily applicable to the explanation of the spread of malignant growths in the tissues of the body. Carl Lewin[4] has urged, on theoretical grounds, the necessity of such a conception. A critical discussion of the subject of tumor metastasis cannot be attempted at this time, but we should like to point out that the conception of ameboid migration of tumor cells explains most reasonably the invasion of tissues, lymph-spaces, and lymph-vessels and blood-vessels by malignant growths. It is especially helpful as an explanation of the dissemination and localization of cancer in serous cavities.

DUODENOJEJUNOSTOMY

FOR THE CURE OF POSTOPERATIVE REGURGITANT VOMITING OF BILE AND PANCREATIC JUICES, FOLLOWING GASTRO-ENTEROSTOMY

P. S. P. ST. L. MONCURE
NORFOLK, VA.

Necessity is the mother of invention, and it was necessity that forced me to "dig up," so to speak, the ascending or terminal portion of the duodenum and "buttonhole" it to the distal portion of the jejunum in the case of a patient operated on six weeks previously for ulcer of the stomach, in which a posterior, no-loop gastro-enterostomy had been performed. The operation, though it relieved the original symptoms entirely, yet by some spur or kink occurring at the anastomosis, caused, about every second day—sometimes oftener—a profuse vomiting of biliary and pancreatic fluids. This vomited material rarely contained any food; and, although great quantities of fluid would be vomited at one time (at least a quart sometimes), it did not accumulate in the stomach, as lavage just before vomiting commenced would often fail to bring any of it away—the water returning clear—when, in less than an hour, bright yellow bile with no food particles would be vomited.

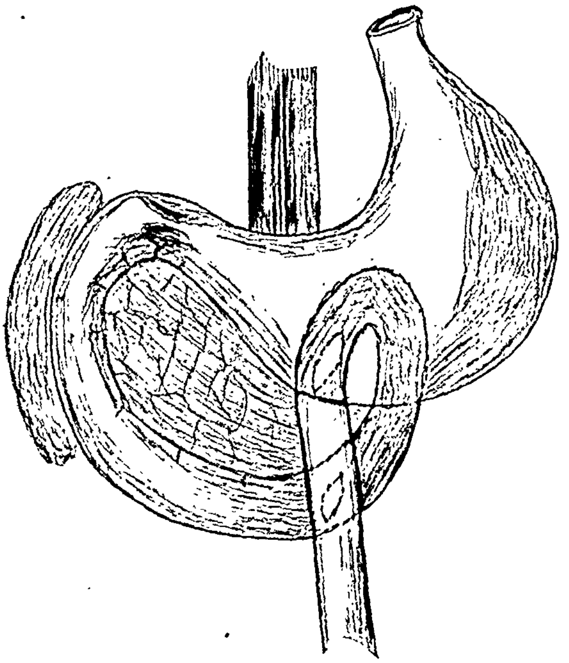
The operation which I performed for the relief of this regurgitant vomiting is not necessarily tedious or long. I believe that it will be performed more frequently in the future, primarily perhaps through election, to prevent the possibility of regurgitant bile-vomiting, and secondarily—as was my case—through necessity. The operation consisted of anastomosing the ascending or terminal portion of the duodenum—just as it turns upward—to the jejunum, for the drainage of bile and pancreatic fluid. The operation is best described by citing the case:

History.—Mrs. S., aged 28, white, married several years, having no children, formerly a seamstress, came to me July 5, 1909, with the following symptoms: pain in epigastric region; periodic vomiting some hours after eating; emaciation; history of vomiting for fourteen years; blood said to have been vomited years ago; none in recent years. The patient was having a temperature every day from 99 to 100.5 F., she had irregular chills, and vomited a great deal. She improved somewhat on stomach lavage, diet, and drugs, but after three weeks' trial, consented to an operation. Lavage was kept up until the operation was performed, July 30. I did the no-loop operation of posterior gastro-enterostomy, as described by Moynihan, the ulcer being at the pyloric end of the stomach. The patient recovered very rapidly and left the hospital in less than two weeks, vomiting in this time only once or twice. She very soon, however (in a week or two), began to vomit great quantities of clear bile. The patient would vomit a great deal, and then have a period of rest for a day or two, especially if given a purgative. She never vomited food; had a most excellent appetite, and would become ravenously hungry just after vomiting the bile. I began to irrigate the stomach again every morning before breakfast, but seeing no benefit after ten days' trial, I finally suggested another operation which the patient, after a few days more of vomiting, urged me to perform at once. This was done October 9, sixty-nine days after the first operation.

---

[4] Lewin, Carl: Die bösartigen Geschwülste, 1909, Leipsic.

Operation.—I went in to relieve the vicious circle, and intending undoing my work on the stomach, if I could not see any other way to do it. Adhesions were so dense around the site of my first operation that it would have been very difficult to undo the work. The engorgement of the bile and other fluids in the duodenum, however, made it stand out very prominently, so I at once decided to work up this ascending portion of it, and make a lateral anastomosis with the descending or distal portion of the jejunum, about 2 or 3 inches below my first operation. I used a Roosevelt clamp and had no great difficulty in doing the anastomosis. Barring a rather protracted period of nausea and retching following the operation, or rather, the anesthetic, which she took poorly, the patient made a rapid recovery. She has never vomited any bile since, and fourteen months after the operation was in most excellent health, having fattened about 35 pounds.



Duodenojejunostomy after a gastro-enterostomy, the ascending portion of the duodenum being joined by a lateral anastomosis with the jejunum 2 to 3 inches distant from the gastrojejunostomy.

The points to commend the operation are these: The possibility of draining the duodenum directly into the jejunum—a safety-valve, so to speak, in the operation of the gastro-enterostomy—which can be done either at the time of the gastro-enterostomy operation, or later if it becomes a necessity. Either a suture, side-to-side anastomosis may be performed—as was done by me—or a Murphy button may be used. I prefer the former, however. I have performed posterior gastro-enterostomy since, but did the operation as described by W. J. Mayo, and, having no subsequent vomiting I have had no opportunity of performing again the operation described above. I have since twice operated on the cadaver, however, and had no difficulty in pulling a loop of duodenum through the peritoneum covering it, and anastomosing it to the jejunum.

Vomiting of bile from any cause can be safely and comparatively easily corrected without having to undo the work on the stomach—when it has been performed—which work may, indeed, be serving a good purpose. The operation is more difficult than a simple gastro-enterostomy, yet it is not a desperate operation and should not take any longer than gastro-enterostomy. It is an operation that will not be performed very often, as the necessity for it is rare, and indeed will become more so; but it can be done; and with marked benefit to the patient. I know of one or two patients now walking around the country on whom gastro-enterostomy has been performed, and who suffer so much from vomiting or other causes, that it would be well for them if they had a little safety-valve to let that bile directly through from the duodenum into the jejunum.

I hope it will be my pleasure some day to hear that some one else has tried the operation with the same happy result.

THE DIAGNOSIS OF MAMMARY TUMORS

WILLIAM L. RODMAN, M.D., LL.D.
Professor of the Principles of Surgery and Clinical Surgery, Medico-Chirurgical College; Surgeon to Medico-Chirurgical, Presbyterian, and Philadelphia General Hospitals
PHILADELPHIA

Twenty years ago I felt sure that a differential diagnosis between benign and malignant tumors of the mammary gland could be made with reasonable certainty. An increasing experience has taught me year by year the fallacy of this opinion, which, I may say, was at the time quite orthodox. Then benign growths were considered to comprise less than 10 per cent. of all mammary neoplasms. We now know that this estimate of Gross and others was far too small, just as we also appreciate that their estimate of sarcomas was much too large. To-day we increase the number of benign growths measurably and restrict the number of sarcomas greatly. Gross estimated that non-carcinomatous growths comprised 18.27 per cent. of mammary neoplasms, and that they were about equally divided between benign growths and sarcomas—9.52 per cent. of the former and 8.75 per cent. of the latter.[1]

I have carefully analyzed the statistics of 5,000 cases of mammary tumors, taking them largely from German clinics where accuracy was likely to obtain, and as a result have found that 16.5 per cent. were benign and that 2.7 per cent. were sarcomas. Thus we find 19.2 per cent.—slightly more than Gross found—non-carcinomatous, but, unlike him, find that sarcomas comprise only a very small part of such lesions and may, indeed, be considered as rare in this situation.[2]

Bloodgood,[3] in an analysis of 694 mammary neoplasms in the Johns Hopkins Hospital, encountered 14 sarcomas, or exactly 1.5 per cent, a still smaller proportion than we found.

It is of the greatest importance to settle this question before taking up the differential diagnosis, as it is my belief that the comparative rarity of sarcoma in the breast is not generally appreciated. Its infrequency in this organ is in marked contrast to its frequent occurrence in many others. At the same time it is now appreciated more than ever before that many of the benign tumors tend markedly, in time, to undergo malignant transformation; and so much so is this the case with some of them, notably the papillary cystadenomas, that they should be looked on from the very beginning as potentially malignant.

Fig. 6.—Growth clinically diagnosed as a sarcoma in a woman 47 years old. Pathologically diagnosed as either a myxoma which has undergone sarcomatous change, or benign growth.

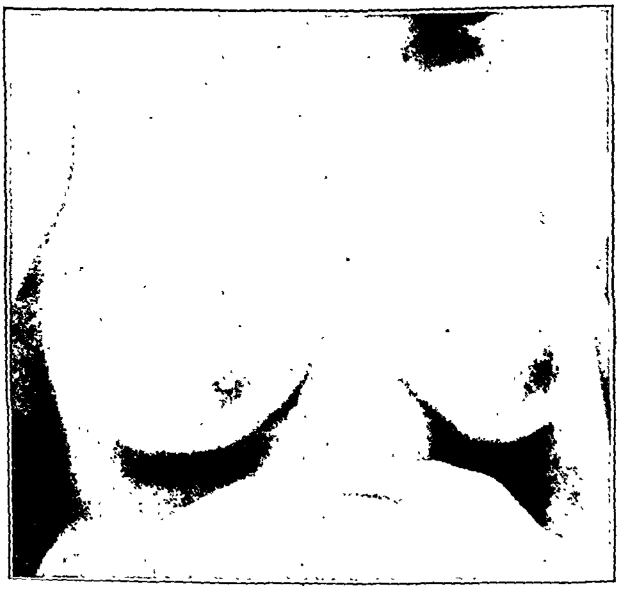

Fig. 8.—Periductal fibroma (fibroadenoma), the largest the author has encountered. In size and shape it resembled a goose egg. Photograph showing tumor after removal shown on page 112 of the author's work on Diseases of the Breast.

ABNORMAL INVOLUTION

Another condition of the greatest importance and frequency has been given much attention during recent years, and its careful study has shown that it manifests a decided tendency to result in carcinoma. I refer to abnormal involution, or, what is perhaps a better term, fibrous and glandular hyperplasia with retention cysts (Whitney), or senile parenchymatous hypertrophy (Bloodgood). It has also been called Schimmelbusch's disease, the disease of Reclus, general cystic disease of the breast, etc. Warren, in a careful analysis of his series, found resulting or coincident carcinoma in 13 per cent. of his cases; Greenough and Hartwell in 10 per cent. of theirs; other authors have made a much higher estimate, some as high as 50 per cent. This condition is most likely to be encountered between 40 and 50 years of age, though it often occurs much earlier and not infrequently later. Thrice within a year I have encountered it resulting in malignancy in women aged 36, 38 and 41 years. All the patients were unmarried. It is far more likely to occur in maiden women, married women who are sterile or in mothers who have not suckled their children. All parts of the breast may be involved, but in my experience, if the condition is limited, as it sometimes is, to a single quadrant, it is most likely to be the lower and outer one. Occurring usually at the cancer age, having clinically many of the signs of malignant dis-

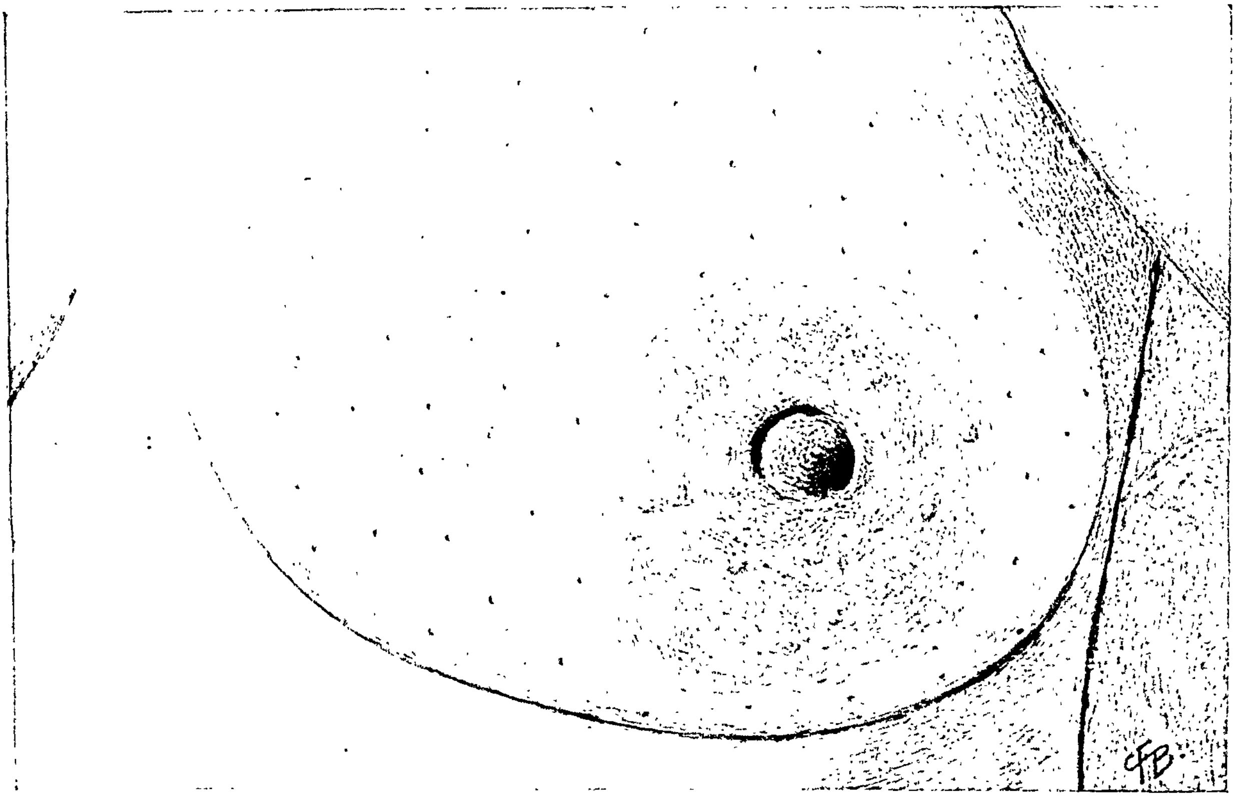

Fig. 1.—Acute cancer in a patient 45 years of age. The color of the skin is accurately portrayed in the drawing, also the indentations resembling the skin of an orange.

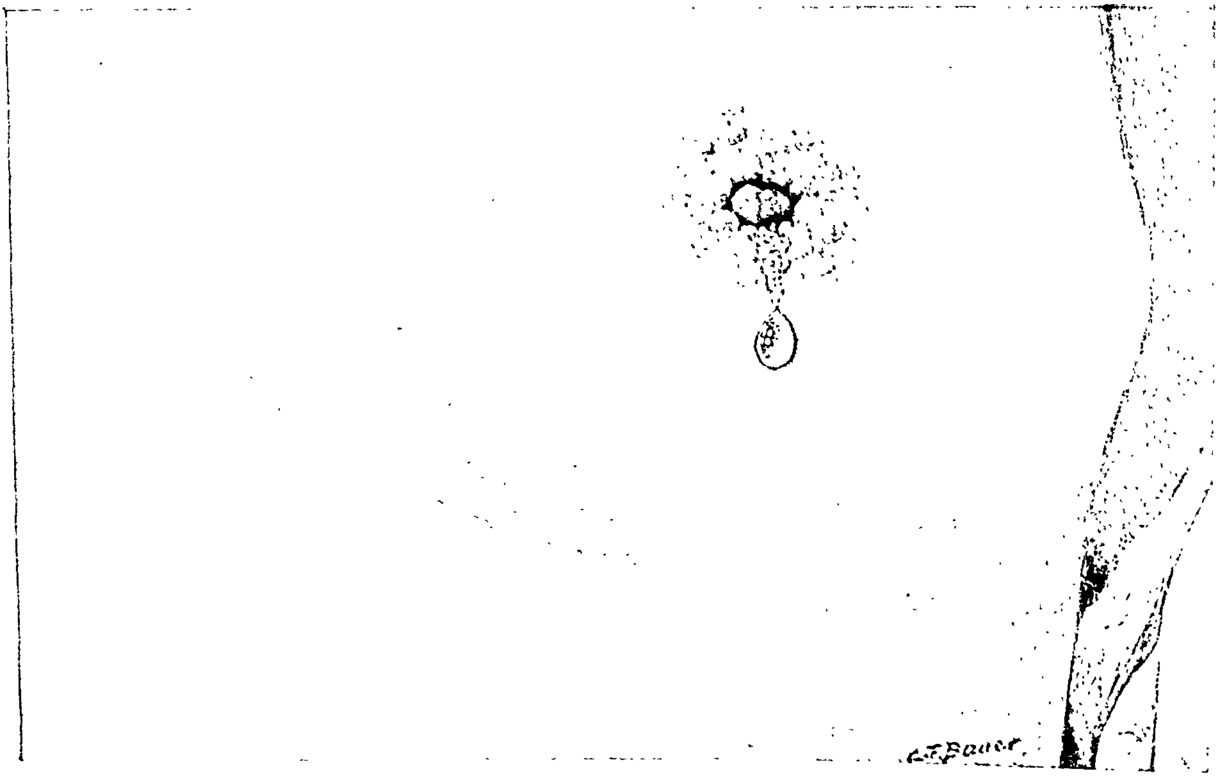

Fig. 2.—Typical retraction of the nipple, also a watery discharge therefrom, in a patient 58 years of age with abnormal involution. The discharge at times is sanguinolent.

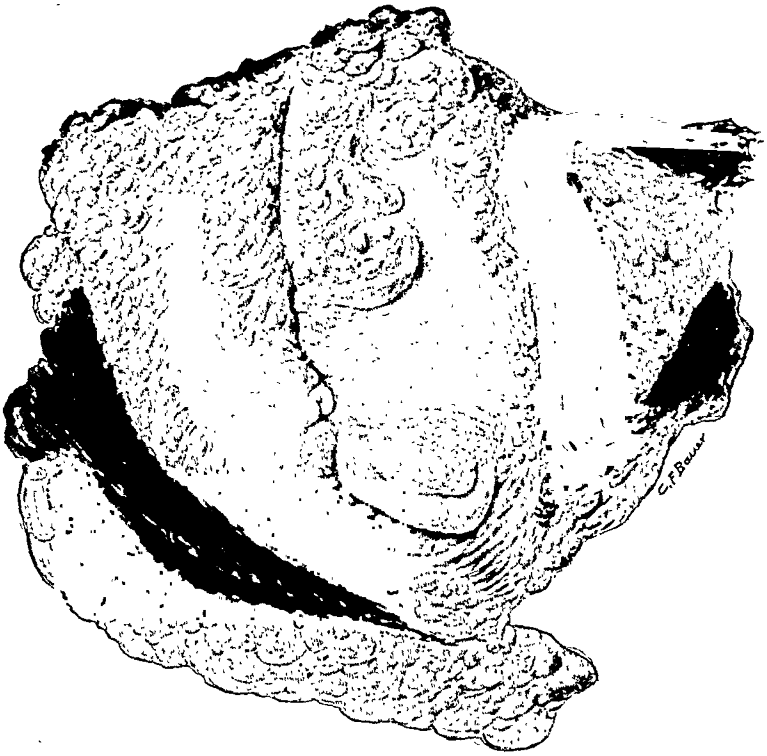

Fig. 3.—Cross-section of breast after removal. No evidence of malignancy. Typical abnormal involution.

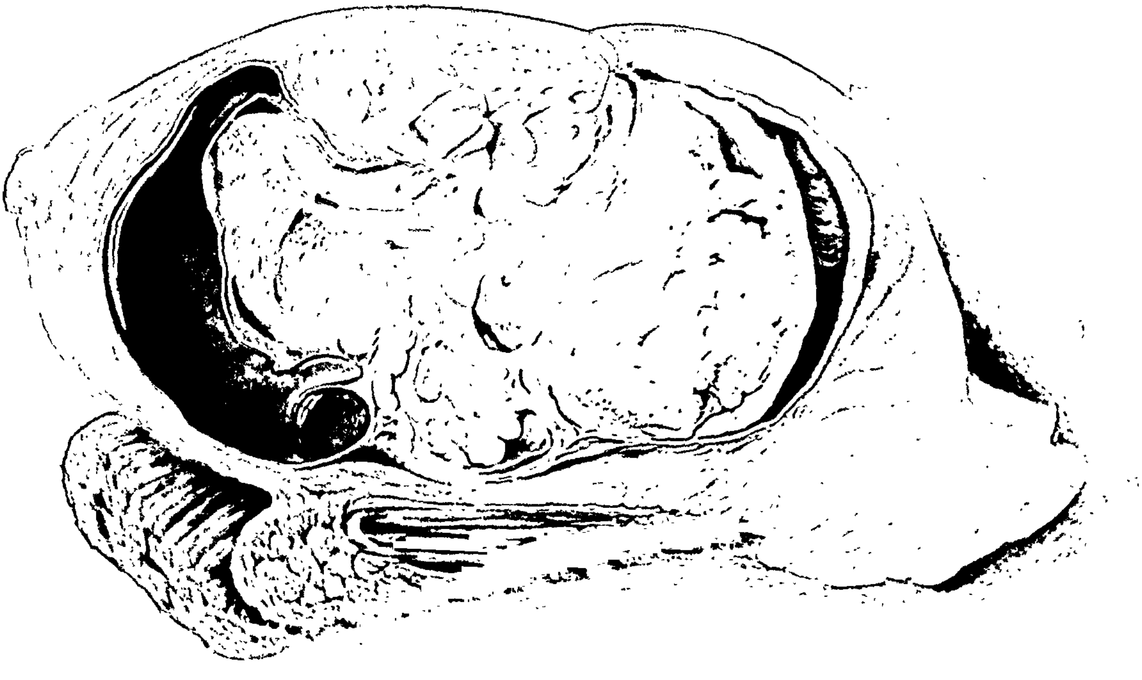

Fig. 4.—Cross-section of sarcoma of the breast which in places has undergone marked cystic degeneration. The case is interesting from the fact that it has been considered by some excellent microscopists as showing carcinomatous spots also.

case, its recognition becomes a matter of the first importance. More than any other condition will it, in my judgment, occasion embarrassment to the diagnostician and perplexity to the surgeon even at the time of operation. Usually its nature will be revealed after incision and macroscopic examination, particularly if it has advanced to what Bloodgood has described as the adenocystic stage, or where there are numerous small, almost microscopic cysts. But in the first or hyperplastic stage nothing short of the microscope will positively reveal its nature. I shall subsequently refer to it more at length.

I would again emphasize the danger of coincident or resulting carcinoma, and that it is too great to be assumed until every safeguard has been taken. In the cases at the Hopkins Hospital associated with carcinoma, fourteen in number, all were, according to Bloodgood,[3] of the adenocystic type. This is most suggestive and should influence materially the treatment.

The several forms of mastitis, pyogenic and non-pyogenic, will not infrequently embarrass even the most careful and expert diagnostician. So great a surgeon as von Langenbeck amputated the entire breasts in at least two patients without suspecting that he was dealing with a simple inflammatory lesion (Keen[4]). All have encountered instances of mastitis in nursing mothers which for a time at least were puzzling, particularly when occurring during the first three or four months of lactation.

ACUTE CARCINOMA

I would here call attention to acute carcinoma of the mammary gland, which so closely simulates inflammation that Volkmann has described it under the name of carcinomatous mastitis. It usually begins as a diffuse rather than a discrete process, in this respect differing from the ordinary forms of carcinoma. Not infrequently has it been associated with pregnancy. Whether such be the case or not, it runs a remarkably rapid course, oftentimes destroying life within six months. The entire gland is enlarged, hard, tender, and the skin covering may be red and edematous. The symptoms of cachexia manifest themselves early and general metastases occur quickly.

I have encountered four well-marked instances of this affection during the past eighteen months. Three of them began as diffuse processes and had been treated with local applications with the belief that they were abscesses. One of them was actually incised. One of these occurred in a woman 45 years of age who had not been pregnant for twenty years. She was treated for several weeks in the out-patient department of the Pennsylvania Hospital, where, I assume from her statement to me and the nature of the local treatment employed, that a diagnosis of mastitis had been made. When I saw her later a diagnosis of acute carcinoma was evident. The breast was at least one-half larger than its fellow, the skin covering red, edematous and tender. The glands of the axilla were extensively involved and there were numerous shot-like bodies in the skin between the nipple and axilla. A complete operation was at once performed, but more with the hope of giving temporary relief to the intense pain from which the patient was suffering than with any expectation of a permanent cure. She lived more than six months after operation, dying from metastases to the lungs, liver and opposite breast.

The second case I saw at the clinic of Dr. W. L. Estes, at South Bethlehem, in a stout woman about 45 years of age. The appearance of the breast was almost identical with that in the case just described. It was explored under the belief that it was inflammatory, but the exploration was at once followed by a complete operation. I have no records of this case, as it occurred in the practice of another surgeon.

The third case I saw November, 1909, in a woman aged 35. She noticed, four months previously, when she was one month pregnant, a small lump in the upper and outer quadrant of her left breast. At the time when she first consulted me she was five months pregnant and the disease had advanced so rapidly that the entire breast was enlarged, tender and involved throughout. If her statement that it began and for three months remained as a small lump in the upper and outer quadrant of the breast can be relied on (and I am not disposed to question it, inasmuch as the breast was harder and more involved at this point) it indicates that the disease sometimes begins as a discrete process. S. W. Gross reported a similar case.[1] There were several shot-like bodies in the skin over the outer hemisphere of the affected breast.

I explained to her husband, a dentist with medical training, that the outlook was a gloomy one, and that the operation promised little further than temporary relief from her pain, which was marked, and improvement in her mental condition. She was greatly distressed in mind, worrying constantly about her condition. Her husband insisted on an operation, which was performed in the Presbyterian Hospital. She experienced entire relief, mental and physical, for nearly two months.

Later I was called in consultation by Dr. W. R. Nicholson, who had been engaged for her accouchement. She was then suffering great abdominal pain due to the conjoint pressure occasioned by a very much enlarged liver and a uterus seven months pregnant. He believed, and I concurred in his opinion, that a premature delivery would soon be necessary. This was brought on a fortnight later, the patient dying about two months subsequently.

On May 17, 1910, I operated in another and most typical case of acute cancer, which had been seen and referred to me by Drs. Darnell and Stewart of Atlantic City. The patient was 45 years of age, married, with one child 24 years old. She had not been pregnant since, but had had an abscess of this breast after her child was born. Attention was not attracted to the breast until three weeks prior to operation, when it was seen to be enlarged somewhat and the site of dull pain and throbbing at night. At the time of operation the integument was distinctly reddened and presented the most characteristic orange-skin appearance that I have ever seen. It is quite well portrayed in the colored drawing herewith shown (Fig. 1).

Of the four cases of acute cancer that I have encountered in the past eighteen months only one was associated with pregnancy. In all of the others the patients were about 45 years of age and none of them had been pregnant for many years.

I have partial records of other cases of acute cancer seen and reported by Prof. Edward P. Davis and others. I am sure that the condition is more common than has been hitherto thought, and that it is perhaps as frequent in non-pregnant as it is in pregnant women.

DIFFERENTIATION OF CYSTS

Difficult as it is to diagnosticate the several conditions already mentioned, it is more difficult to differentiate between benign and malignant cysts, with or without a discharge from the nipple. The character of the discharge, when present, is by no means the aid to diagnosis that I formerly thought and that some others still think it to be. A scanty, thin, sanguinolent discharge is certainly suggestive of carcinoma, whereas a mucoid one is evidence of a benign growth. Thick, granular contents always suggest malignancy. A discharge of blood or markedly bloody fluid strongly suggests an intracystic papilloma. The latter condition, though originally benign, shows a marked tendency to undergo malignant change. Unless a discharge of blood can be clearly shown to have resulted from an intracystic papilloma the malignancy of the cyst should be assumed and the entire breast removed. A more or less blood-stained fluid, however, is now and then found discharging from the nipple in association with abnormal involution.

---

[4] Keen: Amputation of the Female Breast, Cleveland Med. Gaz. December, 1894.

I have encountered several cases of this nature, one that of a colored woman, aged 39, kindly sent in to my service at the Presbyterian Hospital by Dr. Edward B. Hodge on December 1, 1909. She was married, had borne five children, the youngest being 11 years of age. There had for two years been a watery discharge from the left nipple, which in time became yellow and afterward noticeably bloody. The breast was explored by the plastic resection method of Warren. A rather large cyst was found behind the nipple. In addition there were numerous shot-like cysts throughout the gland, which caused me, in spite of the frozen section report, which indicated the part examined to have been benign, to sacrifice the entire breast. It was a typical case of abnormal involution. Had there been only the single cyst behind the nipple I should not have resorted to such drastic treatment, but the associated minute cysts scattered throughout the breast caused me to feel that the patient's safety demanded removal of the entire breast.

I recently encountered in a widow, aged 58, a typical case of abnormal involution with a discharge from and *marked retraction of the nipple.* The discharge, which began seven or eight years ago, was first watery, later on becoming yellowish, and for the last year has been at times bloody. The retraction of the nipple has, so she states, been evident for two years, but during the last six months has been marked. Notwithstanding the discharge and retraction of the nipple, a clinical diagnosis of abnormal involution with cysts was made and complete removal of the breast advised. It was practiced on April 21. The condition before operation is well shown by Figure 2. The macroscopic appearance of the removed breast is also shown in the colored drawing (Fig. 3).

The microscopic report confirms the clinical diagnosis, showing no malignant change whatsoever. The case is interesting on account of the discharge from and marked retraction of the nipple in association with abnormal involution.

It is of the utmost importance to recognize cancerous cysts before or at the time of operation, for if such is not the case the prognosis is extremely bad. Both Halsted[5] and Bloodgood[3] positively state that not a single permanent cure has resulted from operations performed in the Johns Hopkins Hospital when the cancerous nature of the cyst was overlooked at the time of the first operation. Even though soon afterward a second and complete operation was done, the ultimate result was invariably bad.

I made such a mistake in September, 1906, when operating on a patient with a very large cyst situated in the lower and outer quadrant of each breast. Each cyst was as large as a tangerine orange and contained several ounces of a thin, brownish fluid. My pathologist was not present prepared to make frozen sections, having misunderstood the time of our engagement. The character of the fluid aroused my suspicions and almost all of each breast was removed. The muscles, however, were not disturbed, nor were the axillæ cleared. I confess that I was somewhat surprised to receive Prof. Joseph MacFarland's report, ten days after operation, stating positively that each growth was a medullary carcinoma. Feeling it my duty to suggest a second and more thorough operation, I candidly explained the facts to the patient, admitted my mistake and requested the privilege of doing a second operation. This was declined. I am happy to state that the patient when examined for me by her physician, Dr. John B. Cassidy, of Burlington, N. J., was reported as perfectly well generally and free from recurrence locally. It is nearly four years since the operation.

RETRACTION OF NIPPLE

Retraction of the nipple is most significant, but not, as often stated by some high in authority, *pathognomonic* of carcinoma. In the first place it will be encountered in only 52 per cent. of undoubted cancers—those which are situated behind or sufficiently near the nipple to compress and pull on its trabeculæ; in the second place, retraction sometimes is present, in more or less degree, in perfectly benign conditions—as, for instance, congenitally depressed nipples; in patients who have had mastitis, with or without abscess; those with marked hyperplasia of the connective tissue in connection with abnormal involution: and in some who have benign tumors. Gross found the nipple retracted in 5.22 per cent. of non-carcinomatous growths. It is, however, in the latter, and indeed in all non-carcinomatous conditions, more or less mobile and rarely if ever infiltrated. In malignant conditions it is both immobile and infiltrated.

FIBROMA AND MYXOMA

It is manifestly impossible for a paper of this character to describe accurately each mammary growth. I shall only refer to the most common benign neoplasms, the adenofibroma or periductal fibroma and the periductal myxoma.

The periductal fibroma is either solitary or multiple, more often the former, and is not infrequently found affecting both breasts at the same time. It is situated indifferently in all parts of the breast. If it is more obnoxious to any portion of the gland it would seem to be the upper hemisphere. It is freely movable, encapsulated, occasionally lobulated, and now and then is the site of moderate discomfort, if not actual pain. In a few instances I have seen rather marked pain associated with very small fibromas. It is said to follow trauma in from 10 per cent. to 25 per cent. of cases.

Periductal myxoma is also common in women under 30, but occurs more frequently than does fibroma in older women. It also attains a greater volume, is of more rapid growth and is less apt to be accompanied by pain than fibroma. It is somewhat elastic to the touch, is always lobulated and is more frequently multiple than fibroma.

I have recently operated on a woman 47 years of age for such a growth, which was the largest tumor of this character that I have ever seen. It was of two years' duration. Its growth had been rapid during the past six months, and was accompanied with some pain. The appearance of the breast was so suggestive of malignancy that it was pronounced inoperable carcinoma by a prominent surgeon of this city; hence, he declined to operate. Figures 6 and 7 show the appearance of the breast before operation. This case shows the fallacy of depending on the age of the patient as a guide to diagnosis. The patient's age, and the duration and size of the neoplasm with the discolored skin, certainly indicated the growth to be probably malignant. The absence of enlarged axillary and supraclavicular glands led me to operate. I had made a clinical diagnosis of sarcoma. The pathologists differ as to its microscopic appearance, one maintaining that it is a myxoma which has undergone sarcomatous change, the other denying that there is evidence of malignancy.

---

[5] Halsted: Tr. Am. Surg. Assn., 1907.

DIAGNOSIS

Enough, it seems to me, has been said concerning the several varieties of cysts. Suffice it to say that in the majority of instances they cannot be accurately diagnosticated clinically and their true nature will be revealed on exploration and macroscopic inspection or by means of only frozen sections.

The most reliable evidence of incipient cancer will be furnished by an examination of the entire breast after comparing it with its fellow. If there is atrophy of the superficial fascia over a mass, however small, and if in addition there is dimpling of the skin, however slight, over it, a diagnosis of cancer is reasonably certain, provided one can eliminate a previous mastitis. To detect this atrophy of the superjacent fat, and especially the dimpling or puckering of the skin, over a mass which may or may not be distinctly felt, is not easy if only a cursory examination be made. It is particularly difficult in small, deep-seated retromammary growths. In such circumstances pulling the breast forward with both hands will often exaggerate and make evident dimpling of the skin, and also perhaps retraction of the nipple, when such signs had not hitherto been elicited. A better test in my judgment is to move the breast freely, making it take the widest possible excursion, when the attached skin above is certain to be pulled on and to show noticeable dimpling if there has been any shortening whatsoever of its trabeculæ. In tumors situated superficially, the corrugated or orange-like skin may be either apparent or made so by pinching the skin between the thumb and fingers. Palpation is of the very greatest value. A benign growth feels more or less soft, smooth, circumscribed, encapsulated, and movable; carcinoma is hard, irregular, non-encapsulated, infiltrating, and immovable. Not infrequently are carcinomas movable for a time, but in my experience this is exceptional. Recently I saw, in consultation with Dr. L. W Steinbach and Dr. David Reisman, an unmarried woman, upward of 40, with a small, movable tumor, situated in the inferior and inner quadrant of the gland. It was extremely low down, growing from the periphery of the breast. Its nature was evident macroscopically, and the microscope showed it to be a typical scirrhous carcinoma. Sometimes, a better impression as to the nature of the growth will be furnished by palpating with the flat hand, pressing the breast firmly against the costal wall, rather than by using the fingers alone.

In conclusion, I wish to state positively my conviction that no one, however skilled, experienced, or careful he may be in his examination or in eliciting the history of the case, can safely determine the nature of a lesion before operation in more than 75 per cent. of his cases. In the remaining 25 per cent. *at least* either diagnostic incision or the use of frozen sections will be necessary. There is no doubt but that one of experience in such lesions will, as a general rule, be able to recognize them macroscopically, and it is very much better to do so, when possible, as it does away with the necessity of having present an experienced pathologist with his necessary apparatus. I maintain, however, that it will be only the very experienced surgeon, and moreover, one who has had considerable laboratory experience, who will be able to recognize benign and malignant growths with sufficient accuracy to warrant him in employing or withholding radical operation. It can usually be done in solid growths, but cannot be done with cysts, and the difficulty is greater in abnormal involution.

Macroscopically, periductal fibroma presents a distinct fibrous capsule. The tumor is rather hard and on section the surface is pinkish-white in color, especially in young tumors. In those which have remained in the breast for some years, the color is more apt to be white. The knife meets more resistance in cutting these growths than in sectioning normal breast tissue. There is occasionally slight lobulation. The cut surface is convex. These tumors rarely attain large size, though I have removed one as large as an orange from the upper and outer quadrant in a woman four months pregnant. The method of Warren was followed. Subsequently the child nursed this breast. The patient called to see me recently, four years after operation, to report herself as well and to thank me for sparing her breast.

Figure 8 represents very well the appearance of the breast before operation.[6]

A periductal myxoma also presents a fibrous capsule. To the palpating finger there is a more or less characteristic elasticity. The growth sections easily and the cut surface is distinctly lobulated. The glistening myxomatous lobule projects beyond the ring-like depressions of the firmer connective tissue.

The gross pathology of abnormal involution depends on the stage of the process. The early changes are those of hyperplasia. The affected breast is probably slightly larger than its fellow. It is firmer, but not usually uniform in this firmness. When cut, the breast is found to contain an excess of connective tissue, although the parenchyma is also increased. There will nearly always be minute cysts found here and there, no matter how early the process is discovered. Later on, these tiny cysts dilate, and then the cystic stage may be said to have been reached. The thickened areas are not so hard as those characteristic of scirrhous carcinoma, and do not show the same tendency to infiltrate the surrounding fat. The color is whiter than carcinoma. The lymph-nodes may be somewhat enlarged, but do not show the appearance typical of cancer.

It is exceedingly difficult to differentiate abnormal involution from scirrhous carcinoma, and in fact, it is my opinion that it frequently cannot be done without the aid of the microscope. Scirrhous carcinoma has certain characteristics that should be recognized from gross appearances. It usually begins as a more or less localized area of intense hardness, with the characteristic adhesions to skin and muscle, with, frequently, retraction of the nipple. On section, the tissue cuts with increased resistance, but it is perhaps not so difficult to section as an area of abnormal involution. The color is distinctly gray, a contrast to the white normal breast, and dense strands of connective tissue may be seen running between yellowish streaks composed of epithelial tissue. The cut surface retracts after sectioning. The mass can be seen to have no definite limitations, but to be sending infiltrating processes in various directions. Of course, if there have been metastases to the lymphatic glands in the axilla, the diagnosis of malignancy becomes more certain. Metastases may be recognized in general by large, white, firm glands which, if carefully examined, however, will show some remaining portion of the normal gray lymphoid tissue.

---

[6] The appearance of the tumor itself after removal is shown in Figure 20, page 112, in my book on Diseases of the Breast.

FROZEN SECTIONS

I am fully aware that some excellent microscopists more or less discredit the reliability of frozen sections and do not think freshly stained as reliable as fixed specimens. I am not sufficiently experienced in microscopy to discuss this subject. I do know, however, that in more than fifty cases where frozen sections have been made for me during the past seventeen years, but two mistakes have resulted. One of them was made by a young man, inexperienced in the method, who volunteered, in the absence of my customary pathologist, to act for him. He had never resorted to the method before. He reported a case of abnormal involution in a woman 46 years of age as malignant, when a subsequent and more careful examination failed to reveal positive evidence of cancer. I do not think, however, that a mistake was made in sacrificing the entire gland in this instance, inasmuch as the breast was affected throughout by well-marked abnormal involution. Moreover, the patient's mother and sister had died of cancer of the breast. The second mistake was made in a case in which a clinical diagnosis of probable carcinoma had been made in an unmarried woman 41 years of age. It was more than pardonable, as when the second examination was made from fixed specimens ten days later, not the slightest evidence of malignancy was encountered until the thirteenth section was examined. So the mistake might just as well have occurred as a result of the second examination as the first, had not so many sections been prepared and carefully examined. The result of the second examination was promptly and candidly reported to the patient, who was fortunately intelligent enough to accept it in the proper spirit and submitted the next day to a radical operation. I am pleased to state that at the end of eighteen months she remains entirely well.

It is most important to give to the pathologist the entire tumor, and not a small portion taken at random. The mistakes reported are not due to the method or principle, but to its interpretation. In other words, the surgeon, and neither the method nor the microscopist, is at fault.

Dr. Charles Mayo and his pathologist, Dr. Louis B. Wilson, write me that during the last five years more than three hundred tumors of the breast have been removed and a microscopical diagnosis made from frozen sections while the surgeon waited for a report. I quote Dr. Wilson's words:

> No positive diagnosis has ever been given on a specimen which subsequently proved to be not carcinoma. So far as we have any history of the cases, no negative diagnosis has ever been given on a case which subsequently proved to be carcinoma. This rather unusual record is probably due to the fact that the surgeon almost invariably removed the entire tumor with a bit of the surrounding breast tissue before submitting it to the laboratory. When the tumor is very large, of course this cannot be done, but in such cases it is usually possible to make the diagnosis clinically. Cases positively diagnosed as carcinoma clinically are not included in the three hundred. If the tissue contains the pathologic evidence of carcinoma, it can be determined quite as well by a fresh stain as in fixed specimens.

Dr. Mayo also says that he does not think it possible for anyone always to tell the character of a solid or cystic growth of the breast by naked eye appearances. I am certainly of the same opinion, as said before, and I have found frozen sections so satisfactory for many years that I feel it my duty to make use of them in every doubtful case. I invariably explain the situation to the patient and get her consent for a complete operation, should it be necessary. Moreover, there is this advantage in the practice—I find that some patients who would refuse a radical operation offered unconditionally will consent to it on the condition of the microscope's furnishing undoubted evidence of malignancy. In other words, they will consent to a mutilation probably necessary when they would refuse such assent believing that it would certainly be necessary.

OPERATIVE METHODS

During the last five years, I have invariably practiced Warren's method of plastic resection in all benign growths and in those of questionable nature. No matter where the tumor is situated, or whatever its size, be it large or small, I think that the free incision, beneath the breast, which leaves no unsightly scar and which furnishes the best opportunity to examine the entire breast carefully, is much better than a smaller incision directly over the tumor. I have not had in a single case the slightest reason to regret its employment, for in cases of advanced abnormal involution, or even malignancy, I have been prevented from going astray by depending on the report promptly furnished from examination of frozen specimens. In all cases of doubt, the wound is promptly cauterized with the actual cautery, and plugged with gauze while awaiting the microscopic report.

I must insist that the danger of infecting the wound by liberating cancer cells has been greatly overestimated, and that such danger is reduced to a minimum provided the actual cautery is employed. I am unwilling to say that the risk is entirely overcome in this way, but it is rendered so slight that it is practically negligible and is as nothing to the hazards of delay until a clinical diagnosis can be made.

Better results in the operative treatment of malignant disease here and elsewhere must come, if they come at all, only by resorting to diagnostic incision and frozen section reports in doubtful cases. I have greater faith in frozen sections, and always rely on them in hospital practice; but when operating apart from a hospital and a competent pathologist, have tried to teach myself to recognize macroscopically the several conditions likely to be encountered.

I wish to state positively my position concerning incision for diagnostic purposes *only*, the wound being closed and the action of the surgeon governed by a report from the laboratory made days or weeks subsequently. In the light of our present knowledge there is no warrant for such procedure, as cancer cells are disseminated thereby, and a radical cure from a second operation, however early and extensive, is rendered far less likely.

1904 Chestnut Street.

RECENT STUDIES ON LIPOIDS*

W. KOCH, Ph.D.
CHICAGO

The constituents of any tissue can be conveniently subdivided into three main groups, according to their physical properties.

1. Solid aggregates (fat droplets, glycogen granules and solid structures).
2. Colloids (proteins and lipoids).
3. Crystalloids (salts, water-soluble extractives like creatin, etc.).

In the first group, the fat droplets and glycogen granules occupy about the relation to a living cell that the coal in the tender does to a locomotive. They serve as a convenient source of energy, but do not represent an essential part of the functionally active machine. The crystalloids in a good many cases, but by no means in every case, represent end-products of chemical activity, and as such do not concern us here. The colloids, a name originated by Graham,[1] form an essential part of the mechanism of the living cell, and as such represent larger aggregates of molecules, which are on the borderline between suspensions and true solutions.

Their ability to change this state of aggregation is of great functional significance as will be illustrated later. A very good discussion of the properties of colloidal solutions has been given by A. A. Noyes.[2] The colloids of the tissues are further subdivided into two main groups, the proteins and the lipoids. The term "lipoid" was introduced by Overton[3] to designate a class of compounds which are characterized by their solubility in various fat solvents, and occur in large quantities in the nervous system. In their chemical properties and structure the lipoids do not resemble one another very closely, but their relation to fat solvents and their peculiar ability, as distinguished from the neutral fats, to form permanent emulsions or colloidal solutions with water, make it convenient to consider them as a group.

A study of their biologic properties has further served to justify this classification. The credit for first calling attention to certain members of this group belongs and has always been given to Hoppe-Seyler.[4] The pioneer work on the lipoids of the nervous system has, however, been done by Thudichum,[5] and it has been my privilege at various times to call attention to the splendid work of this much-neglected investigator, who during his lifetime received practically no recognition, even from his immediate colleagues. The classification of lipoids given in the table is essentially due to Thudichum, although the term "lipoid," as already stated, was introduced more recently by Overton.

CLASSIFICATION OF LIPOIDS ACCORDING TO THUDICHUM

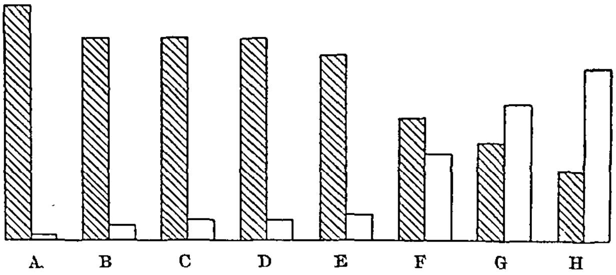
1. Cholesterols (carbon, hydrogen and oxygen).
    Structure: Unknown.
    Example: Cholesterol (formerly incorrectly called cholesterin).
2. Cerebrosids (carbon, hydrogen, oxygen and nitrogen).
    Structure: Unknown.
    Groups isolated and identified: Galactose.
    Example: Phrenosin (cerebrin).
3. Phosphatids (carbon, hydrogen, oxygen, nitrogen and phosphorus).
    Structure: Not satisfactorily known. Esters of orthophosphoric acid.
    Groups isolated and identified: Palmitic, stearic, oleic, linolinic and glycerophosphoric acids, cholin.
    Examples: Lecithin, kephalin.
4. Sulphatids (carbon, hydrogen, oxygen, nitrogen, sulphur, and sometimes phosphorus).
    Structure: Unknown. Esters of sulphuric acid.
    Example: Cerebrosulphatid.

The anatomic term "myelin," introduced by Virchow,[6] and the rather indefinite protagon first mentioned by Liebreich[7] have been omitted from the above classification as not sufficiently well characterized chemically. The chemistry of the above groups is still in an unsatisfactory condition, but a considerable number of investigators are at present engaged on this subject. The biologic significance of the lipoids has also until recently been very much overshadowed by the greater interest in the proteins. The relative proportions in which the two groups occur in various tissues is shown by the illustration.

The fact that most tissues contain more protein than lipoids does not, however, argue for the relatively lesser importance of the latter group, for as will be shown presently, even the comparatively small quantity of lipoids in the erythrocyte have an important biologic function. The biologic rôle of the various lipoids will be considered under the headings as outlined in the table.

CHOLESTEROLS

Cholesterol, or to use the older less correct term, cholesterin, is familiar to everyone as a pearly white crystalline substance, which is found as the constituent of some gall-stones and can sometimes be observed in museum jars in which brains have been preserved in alcohol. Cholesterol by itself is probably of very little value to the organism, but in conjunction with the other lipoids, there is good reason to believe that it has an important function in adding stability to certain membranes. The very considerable quantity in which it occurs in the sheath of the medullated nerve fiber lends support to this suggestion. That it may serve a similar function in the stroma of the red blood-cell has been demonstrated to be probable by Ransom[8] who showed that saponin in producing hemolysis does so by interaction with cholesterin. K. Meyer[9] has lately suggested that the lecithin may also play a rôle in saponin hemolysis.



Proportion of protein (shaded) to lipoid (white) in different tissues. A, erythrocyte; B, striated muscle; C, heart muscle; D, kidney; E, liver; F, brain at birth; G, adult brain; H, corpus callosum.

The recent observations of Faust[10] that the hemolytic substance of the flat worm *Bothriocephalus* is a cholesterol oleic acid ester, is also of interest in this connection, on account of the significance which has been attached to this finding regarding the etiology of certain forms of pernicious anemia. The finding of hemolytic lipoids in cancer tissue may also be mentioned here, but the nature of the lipoid concerned has not yet been made out.

CEREBROSIDS

The principal member of this group, cerebrin, was first described by Müller.[11] The fact that the cerebrosids occur principally in medullated nerve fibers led Takaki[12] to investigate their possible relation to the ability of the tetanus toxin to follow a nerve trunk and thus reach the central nervous system from the periphery. The experiments, which consisted mainly in the study of the power of cerebrin and some of its derivatives to neutralize the toxic action of tetanus toxin, were not very conclusive.

Similar experiments with a greater variety of preparations were tried some years ago in cooperation with the late Dr. H. T. Ricketts. The variations were, however, within the variations to be expected in this kind of work and consequently were never published. The fact that this group contains galactose might suggest a nutritive function for the nerve fiber, if it were not such a common phenomenon to have the organism build up into structural elements and thus render useless as food. certain groups which might otherwise serve as sources of energy. The high carbohydrate content of the chitinous shells of certain crustaceans is a good illustration of this phenomenon.

THE PHOSPHATIDS

The phosphatids, so named by Thudichum,[5] usually appear as yellowish, waxy substances which show some tendency to crystallize when dry, but very quickly soften and lose this tendency when exposed to the air.

Exposure to the air also causes them to darken in color, so that old preparations may appear quite dark. The phosphatid with which we have been up to the present most familiar is lecithin. It was first carefully studied by Hoppe-Seyler[4] and found by him to be pretty generally distributed in all forms of protoplasm. The various subgroups into which the phosphatids have been divided for purposes of chemical study will not be here taken up, but the considerable variety of biologic phenomena will be considered in which this interesting group of lipoids appears to play a rôle.

Relation to Inorganic Salts.—The fact that in the extraction of a tissue with a fat solvent, the greater part of the ash constituents, especially the sodium and potassium, follow the phosphatids, and do not remain behind with the proteins to any appreciable extent, is of significance.

A protein after purification may retain an ash content of 0.5 and 1.0 per cent., but phosphatids will carry through such solvents as anhydrous ether an ash content ranging from 2 to 5 per cent.

The importance of this relationship is further illustrated by direct experiment. It is possible by precipitation reactions on colloidal solutions of lecithin to reproduce both qualitatively and quantitatively the antagonism between calcium chlorid and sodium chlorid observed by Loeb[13] on such living forms as starfish eggs or frogs' muscles. In the presence of sodium chlorid the amount of calcium required to cause a precipitate is materially increased. As the amount of sodium chlorid is increased, greater amounts of calcium are required; in other words, sodium chlorid antagonizes the calcium, an action which Mathews[14] has shown to be due to the chlorin ion.

Williams[15] has made the interesting observation that the increase in sodium chlorid, however, cannot be carried beyond that of a physiologic salt solution. As soon as the concentration exceeds this, the chlorin of the sodium chlorid can no longer antagonize the calcium, and the sodium now begins to aid the calcium in the process of precipitation.

The importance of a physiologic salt solution appears, then, to be not only to keep up the osmotic pressure, but also to keep the physical state of aggregation of the colloids at an optimum. It seems tempting to bring the phenomenon of chlorid retention in the tissues in certain diseases into relationship with changes in the colloids, which so change their state that this optimum is shifted and a higher concentration of sodium chlorid can still antagonize the calcium.

Relation to Hemolysis.—Hemolysis may be considered as a type of reaction in which a stroma or plasma membrane, which is considered by Overton to contain lipoids, undergoes changes of permeability as the result of variation in external conditions. Hemolysis is thus a special case of that larger type of biologic reactions of which plasmolysis in plant cells, cytolysis in animal cells, the fertilization of the egg cell and the phenomenon of bacteriolysis are further examples.

Hemolysis by cobra venom, according to Ehrlich, takes place as the result of the interaction of three factors—the amboceptor or cobra venom, the complement present in the serum and the receptor group in the corpuscle itself. Kyes[16] has made the very interesting observation that lecithin, which is itself not hemolytic, can enter into the reaction and behave like the complement. The reaction of cobra venom with lecithin was interpreted by Kyes as in the nature of a combination with the formation of a cobra lecithid. Manwaring,[17] in a recent repetition of this work, has come to the conclusion that the cobra lecithid of Kyes is a lecithin from which the oleic acid has been split off by a lipolytic ferment contained in the venom. The fact that the cobra lecithid, the product of the action of cobra venom on lecithin, is highly hemolytic, remains unaltered by this interpretation.

More recently Noguchi[18] has shown that in the Wassermann complement deviation reaction for syphilis, the antigen may be in the nature of a lipoid, which in its solubilities resembles the phosphatids.

Relation to Products of Tissue Metabolism.—Williams[15] has shown that lecithin may combine with and be altered in its state of physical aggregation by such tissue metabolites as ammonia and bile-salts, epinephrin, etc.

In the case of the epinephrin it has the power to protect this substance from oxidation. Thus a watery solution of epinephrin, which quickly oxidizes and loses its physiologic activity on standing, can in the presence of lecithin retain its activity for weeks, provided bacterial decomposition of the lecithin is avoided.

Relation to Drugs.—The theory of narcosis originated simultaneously by Overton[3] and by Meyer[19] was one of the first studies to call attention to the subject of the lipoids in relation to pharmacologic problems.

A glance at the illustration will show why a substance soluble in fats or lipoids should become largely localized in the nervous system, on the theory that a substance distributes itself between two solvents in proportion to its relative solubility in each.

The very marked affinity which the anesthetics and hypnotics possess for the nervous system is correlated with the high lipoid content of that tissue. The assumption that changes in the physical state of aggregation of the phosphatids, induced by the presence of the anesthetic, are responsible for the phenomenon of narcosis, was investigated by McLean[20] and found not to hold as far as the general phenomenon is concerned.

He did find, however, that chloroform changed the state of aggregation of lecithin, and presented evidences of chemical combination, while ether, alcohol and chloral did not. It seems more reasonable therefore to bring this phenomenon into relation with the well-known difference in the elimination of ether and chloroform and the consequent tendency of the latter to produce delayed poisoning.

An interesting clinical application of the theory of Overton and Meyer has recently been made by Graham.[21] On the basis that the nausea and vomiting following an operation are largely due to the excretion of the anesthetic into the stomach, he gives his patients pure olive oil. This absorbs the anesthetic and has so far been attended with very satisfactory results.

Overton also extended his theory to other drugs and suggested that the alkaloids may be taken into the nervous system by the lipoids. He does not give any experimental evidence. This has been supplied by Mostrom[22] in the case of strychnin in the following experiment:

The free alkaloid strychnin, which is only very slightly soluble in water, is shaken with water for one hour; 0.3 c.c. of the resulting filtered solution injected into a 40-gm. frog, requires thirty to forty minutes to produce tetanus. If instead of distilled water an emulsion of lecithin is used, a much larger quantity of strychnin goes into solution and tetanus now occurs in two or three minutes.

We see from this that the lecithin by combining with the strychnin is the means of bringing it into solution. We can conceive that the lecithin of the nervous system picks up the strychnin from the blood-stream in a similar fashion. Lecithin would be behaving, then, in this case as a chemoreceptor group in Ehrlich's interpretation of the term. The fact that the strychnin, when combined with this chemoreceptor group, can still exert its physiologic activity, is characteristic of this type of combination. If we were dealing with a toxin of the nature of tetanus toxin, which also has an affinity for the nervous system, the combination would be much less dissociable, and the toxin consequently not free to act. (The chemical nature of the receptor group for tetanus toxin has not yet been determined: see under cerebrosids.) This difference is dissociability between an alkaloid receptor combination and a toxin receptor combination is undoubtedly one of the reasons why all attempts to produce antiserums for alkaloids, as for instance morphin[23] have failed.

Relation to Problems of Specificity.—It is tempting to extend such observations as the above to the problem of the specific attraction which certain tissues have for certain drugs. An observation which has a bearing on this was made by Erlandsen[24] when he discovered a phosphatid to which he gave the name "cuorin," which occurred only in heart tissue and in no other type of muscular tissue. Whether or not such compounds can be brought into relation with such specific affinities of the tissues remains to be more carefully studied. The observation made by Pike[25] that the proportion of potassium to sodium is higher in kephalin (2 to 1) than in lecithin (2 to 8) may be interpreted as indicating a specific attraction of kephalin, as distinguished from other colloids, for potassium.

This observation has an important bearing on the ability of tissues to preserve a higher concentration of potassium than occurs in the surrounding fluids.

SULPHATIDS

This interesting class which occurs largely in the medullated nerve-fiber has only recently been obtained in a state approaching purity, and consequently very little studied biologically.

In concluding, then, it is interesting to note the considerable number of biologic phenomena in which the lipoids play a rôle. The only practical application which has come to the attention of the medical profession has been the attempt to exploit lecithin commercially as a brain and tissue food. The fallacy of this I have already pointed out in a previous article,[26] and it is to be hoped that such attempts will not detract from the interest which should attach to further work on the subject of the lipoids.

A REPORT ON THE THERAPEUTIC EFFICIENCY OF SALVARSAN

C. HUGH McKENNA, M.D.
Surgeon to St. Joseph's Hospital
CHICAGO

During the early part of September, 1910, I personally investigated Ehrlich's work in the treatment of syphilis with salvarsan. I have not made a report earlier, first, because I wished to make some observation of the results obtained by physicians in this country, and to acquire some experience in using the remedy in my own work; and second, because I believed that it would be dangerous to permit the idea to become general that a single dose of salvarsan would permanently cure syphilis.

My own experience with salvarsan, and the observations I have made of this work carried on both in this country and in Europe, lead me to the conviction that under no circumstances should it be used without also using mercury or the iodids. If we can conceive of making a diagnosis of syphilis so early that not a single spirochete has become encapsulated, but all lie free in the circulation, then we might entertain the theory of a single injection of salvarsan destroying completely the invading organisms.

The question naturally arises: What is the rôle of this new treatment, and what is its real merit?

Experience in the treatment of syphilis with the preparation appears to be sufficient at this time to warrant the statement that it is the therapy of election in the following stages of the disease:

1. With the appearance of the chancre, or sooner, if an absolute diagnosis can be made, with the hope that this remedy may reduce to a minimum the possibility of general contamination during this stage of the disease.
2. In all affections of the mouth, throat and mucous membrane of the nose.
3. In the class of obstinate cases with cutaneous lesions that do not yield to mercury or the iodids.
4. In all cases of gummata.
5. In those affections of the central nervous system in which the spirochete may remain as the exciting element.
6. In congenital syphilis.
7. In the galloping syphilis of Unna.

Of course it is understood that before salvarsan is used in any case the tenets of Ehrlich should be fulfilled—that is, that the patient be kept under observation in a hospital for four days, where a careful record of his physical condition may be made, particular attention being paid to the condition of the heart, kidneys, eyes and ears. In other words, aside from the syphilitic taint, the patient must be in a healthy condition. The fatalities and serious complications have occurred in patients with lesions other than those due to syphilis.

Ehrlich's studies led him to believe that parasites can be destroyed only by substances to which they have a certain relation, which substances he designated as "parasitotropes." Poisons which have relations to essential organs he termed "organotropes." Ehrlich pointed out that only such substances can be used as remedies in which organotropy and parasitotropy have a right relation. This investigation led to the conclusion that when a parasitotrope was injected into the host either the invading organisms were immediately killed, or if any organisms lived through this form of treatment they were rendered tolerant to subsequent injections of this substance.

Consequently the early treatment of syphilis by the injection of salvarsan was based on the above theory. It seems difficult to conceive a condition in any stage of syphilis in which every single spirochete was free in the circulation at the same time. One can scarcely reconcile this condition even at the moment of reception of the spirochete into the host because of Nature's ability to wall off invading organisms; yet it is just possible that a complete extirpation of the spirochetes might be accomplished in this way, if the diagnosis of syphilis could be made early enough. It does not seem as though the disease could be recognized early enough to make the hope of having an absolute cure of syphilis from a single injection of salvarsan a well-grounded one.

The determination of the immediate efficiency of this form of treatment is based on the Wassermann reaction becoming negative within a reasonable length of time after the injection, usually in about five weeks. An idea of the efficiency of salvarsan can best be given by recording a brief summary of the results of the Wassermann test in some of the clinics in which this treatment was first carried out.

The following compilation of results is made from a recent report from Dr. Ehrlich, entitled, "Die Salvantherapie: Rückblicke und Ausblicke":

1. In the Weintraud Klinik, 124 *patients in the* second and third stages of syphilis were all Wassermann-positive before treatment. After a single injection of salvarsan fifty-seven became negative, while sixty-seven remained positive. Weintraud was of the opinion that by systematic reinjections it is possible to bring the percentage of Wassermann-negative cases to 90 per cent.; then by the use of mercury to bring about a negative Wassermann in the remaining 10 per cent. of cases.

2. Gennerich[1] treated 81 patients with severe cases and produced a negative Wassermann in all but three cases.

3. Schreiber, Magdeburg, succeeded in producing a very high percentage of Wassermann-negative conditions by a repetition of the injection.

4. Fabry-Dortmund, with the alkaline solution introduced by the intramuscular method, had only six recurrences out of 385 patients treated.

5. Dr. Schulz, Strassburg, by the subcutaneous method, had four recurrences out of sixty-three cases. Two of these returns were due to a gangrenous condition at the site of the injection, which necessitated incision and drainage. All four became Wassermann-negative in a short time, after being treated by the intravenous method.

6. In this country, Murphy, of Chicago, has had an extensive experience in the use of salvarsan. Out of 100 patients treated by the "suprafascial" method, he has had one bad result, which was due to an encapsulation and lack of absorption of the mixture at the site of the injection, that had to be opened and drained. The suprafascial method introduced by Murphy is as follows:

The needle is inserted at the level of the tenth rib, and at a point one and one-half inches from the median line posteriorly. The needle is directed outward and downward parallel to the tenth rib reaching to the fascia overlying the loins, and the mixture is deposited on the fascia.

Another point of much importance to decide in this connection is the safest and most efficient method of administration. Of the various methods used, only two need be considered, viz., the intramuscular (including the suprafascial), and the intravenous. A solution of this problem can best be reached by presenting a brief résumé of the results obtained by some of the most experienced and accurate workers.

The following is a translation of an extract from a letter just received from Dr. Ehrlich, under date of Frankfort a/M., 4 Feb., 1911:

"I should like to remark that I, as you well know, am much in favor of the intravenous injection, and that preferably this should be repeated two or three times in very early cases (the second stage), as Weintraud does in Wiesbaden. He makes an intravenous injection three times within four or five weeks, using 0.4, or at most 0.5 in men, and the result is that in over 90 per cent. of cases the Wassermann reaction is negative."[2]

The results reached, as already cited, by Fabry-Dortmund in a large experience with the intramuscular method, and by many other workers of large experience who use this method of administration, and those of Murphy of Chicago by the suprafascial method, should prove conclusively that the extravenous methods are efficient. Whether this efficiency reaches the same degree as that of the intravenous I cannot say. On the other hand, I can state most emphatically that the latter method is much more dangerous, and while this danger may be reduced to a minimum by scientific management and the experience in technic possessed by the operator, still there is an element of danger over which experience exerts no influence, viz., the possibility that this arsenical preparation undergoes a chemical change when introduced into the direct circulation, which at times may have a deleterious or even fatal effect.

---

[1] Berl. klin. Wchnschr., 1910, No. 46.

[2] "Ich möchte mir noch die Bemerkung erlauben, dass ich, wie Sie wohl wissen, sehr für die intravenöse Injection bin und dass diese zumal bei ganz frischen Erkrankungen (Syphilis II), am besten 2-3 Mal widerholt wird, wie dies Weintraud in Wiesbaden tut. Er injiziert innerhalb 4-5 Wochen 3 Mal intravenös, Männern 0.4 bis höchstens 0.5 und erreicht, damit dass in weit über 90% der Wassermann negative wird."

Since all operations or methods of therapy have as a purpose, first, the saving of life, and second, efficiency, it would seem most rational to conclude by strongly recommending the administration of salvarsan by the extravenous methods, viz., the intramuscular and the suprafascial, and in those cases proving refractive to this mode of treatment, readministering it by the intravenous method.

My own experience in the administration of salvarsan has been by the extravenous methods, both the intramuscular and the suprafascial. Sufficient time has not elapsed to make a complete report on these cases; however, I wish to state that there have been no complications and the patients have experienced very little distress after this form of administration. From a clinical point of view they show evidence of a subsidence of the disease.

CONCLUSIONS

1. The medical profession should use every effort possible to eradicate the idea that appears to have become prevalent in the minds of the laity, and, indeed, of many of the profession, that a single dose of salvarsan will permanently cure syphilis.

2. Salvarsan should be administered under the best scientific conditions possible, which means that no patients should be treated until they have been in a hospital four days and careful records made of their physical condition. Only patients in a healthy condition, aside from the syphilitic taint, should receive this form of treatment. Any attempt to treat patients when these precautions have not been taken, or any unscientific use of the preparation, should be strongly opposed by the profession, as these attempts are sure to result disastrously to the patient and also to detract from the merits of the remedy.

3. Salvarsan is the treatment of election in the conditions of syphilis enumerated in this paper, but under all circumstances should be followed by mercury or the iodids, or by both.

4. Administration by the intramuscular or suprafascial route should first be instituted, as it is the safest method, and in the event of the patient not becoming Wassermann-negative, it is then time enough to employ the more dangerous intravenous method.

100 State Street.

Intestinal Anastomosis.—The various instruments and appliances formerly used to facilitate work on the intestines have nearly all been discarded for the simple but efficient method of intestinal anastomosis by thread and needle. The general condition of the patient should be as near par as is consistent with the exigencies of the case. All organs should functionate properly and the temperature and blood should be about normal, to obtain the maximum results in surgical work on the intestines. The work should be carefully but rapidly performed, which is oftener the case when the surgeon has from practice or experimental work on the lower animals become skilful in the use of needle and thread. A positive blood-supply to the tissues making up the anastomosis is necessary. The end-to-end method is not so certain, therefore the side-to-side anastomosis should be chosen whenever convenient. A. E. Benjamin, in *Lancet-Clinic.*

A CASE OF HEMATOSALPINX WITH CERVICAL ATRESIA

J. R. B. BRANCH, M.D.
Attending Gynecologist, Macon Hospital
MACON, GA.

Patient.—N. H., aged 15, white, schoolgirl, was eldest of three children, complained of pain in the left lower abdominal quadrant with nausea and vomiting.

Family History.—This was unimportant. The mother menstruated at eleven.

Personal History.—Birth was normal. The history was taken after the operation. General health had never been good. During childhood the girl had measles, mumps, whooping-cough, chicken-pox, diphtheria, scarlet fever, chorea and one attack of "slow fever" lasting a week, with severe headache and delirium. She had always been nervous and delicate. Appetite was somewhat inordinate, and she craved unusual and unreasonable foods; digestion was good. There was no nausea or vomiting except during the attacks. Bowels usually moved every day. The urinary condition seemed to have been normal up to present illness, during which she suffered severe dysuria. Following diphtheria and scarlet fever at the ages of 5 and 6, patient had a troublesome white discharge (leukorrhea) irritating but not malodorous. Although 15 years old, the patient had never menstruated. Four years ago her mother noticed that she was unusually nervous, with dark circles under her eyes, and had headache and nausea, and thought that menstruation was about to begin; no flow ever appeared. In February, 1907, following such a train of symptoms as just mentioned, the patient had a sudden severe attack of pain in the right lower abdominal quadrant, associated with nausea and vomiting, lasting three or four days. Each month since, the girl has had headache with dark circles under her eyes. Never has there been a drop of menstrual flow. Similar attacks to the one in February, 1907, occurred in February, 1908, February and June, 1909, and June 12, 1910, the present one.

Present Illness.—Three days before consulting me, the patient began having a dull aching pain, sometimes sharp in character, in the left lower abdominal quadrant. It grew steadily worse and was so severe next day that nausea and vomiting set in. The pain became general and the right side was involved. She was not constipated.

Physical Examination.—Patient was an emergency case, and came to the hospital suffering severe pain in both lower abdominal quadrants. She looked ill. Pulse was 120, respiration 26, temperature 102.4 F., by rectum. The abdomen was rigid, and there was general resistance and tenderness, palpation being most painful in the left lower quadrant. A mass was distinctly felt in the right iliac fossa.

Diagnosis.—A diagnosis of appendix abscess was made.

Operation.—A small gridiron incision was made in McBurney's region. On opening the peritoneum, dark bloody fluid welled out. The examining finger encountered a smooth, elastic, crepitating mass, filling the right iliac fossa and extending to the median line. In appearance the mass was lobulated, and of dark bloody color. As it was impossible to deliver it through the small incision, an opening was made in the median line. The mass proved to be a large left-sided hematosalpinx, with twisted pedicles, containing 8 or 10 ounces of blood-clot. The tube at the cornu measured from 1 to 1.5 cm. in diameter; the ovary could not be distinguished from the mass. It was tied off with catgut and removed. The right tube and ovary were found lying in the cul-de-sac; the tube was dilated slightly, and the ovary enlarged and cystic, measuring 8 or 9 cm. by 4 cm. Both were removed. The uterus was normal. After cleaning out the small amount of dark bloody fluid the abdomen was closed in layers. The appendix was not seen.

Postoperative Notes.—Aside from inability to void urine for five days after the operation, the patient made an uneventful recovery. Temperature reached normal on the fifth day, never being over 101 F. The pulse dropped to 80 on the fifth day. Before discharge from hospital a vaginal examination was made, using a cystoscope. The vulva was normal, the vagina narrow, measuring 9 cm. from a normal hymen to the cervix. There was a white thick leukorrheal discharge. The cervix was flush with the vaginal vault, completely closed, and the os marked with a dimple.

The case was one of cervical atresia, probably caused by the diphtheria or scarlet fever during childhood. The amenorrhea was the result of obstruction and the menstrual flow had accumulated in the tube. The patient, six months after operation, is in perfect health but has not menstruated.

I am indebted to Dr. K. P. Moore for allowing me to report this case, which came under his care in the Macon Hospital.

ARRESTED DEVELOPMENT OF ABDOMINAL PARIETES

ASSOCIATED WITH SHORTENED UMBILICAL CORD

A. G. WILCOX, M.D.
SOLON SPRINGS, WIS.

History.—The mother was a strong, healthy woman, Danish, aged 26, a teacher before marriage, and gave no history of uterine or pelvic troubles. No known relatives have been deformed. It was a first labor and a midwife was in attendance for about twenty-four hours. When I arrived I found the position to be R. O. P. The cervix was dilated to about 5 cm. Mother and fetus were apparently normal. Uterine inertia and powerful uterine contractions alternated for the next five hours without dilating the cervix to any extent. Chloroform was then given, the cervix dilated manually and high forceps applied. After each pull on the forceps, the head sprang back to its original place as if pulled on by elastic band. There was considerable hemorrhage between and during the efforts at traction. After about one hour the head reached the vulva; a pair of hemostats was clamped on the cord and the cord cut. The child was then delivered with ease. The placenta was immediately removed by the hand placed in the uterus. It was attached on the anterior superior part of the interior of the fundus.

Examination of Child.—The child was a female weighing 8½ pounds. A thin semitransparent membrane about the thickness of tissue paper extended from the xiphoid cartilage to one inch below the umbilicus. This membrane was elliptical in shape and about four inches across the broadest part. The abdominal organs—liver, spleen, stomach, and intestines—could be easily seen through this membrane.

The umbilical cord was 12 cm. (5 in.) long and 0.6 cm. (¼ in.) in diameter and lacking in the usual spiral windings. The greatly diminished diameter of the cord and lack of windings give one the impression that the cord was even shorter than 5 inches, its present length; but during the latter months of pregnancy had been elongated at the expense of diameter by the tension of the fetal weight and movements. The specific gravity of the fetus is always greater than that of the amniotic fluid; hence, with a cord suspended from the fundus of the uterus and not long enough to allow the fetus to reach the opposite extremity of the uterus, there would be tension on the cord. (In this case the uterus was 12 inches and cord only 5 inches.)

Operation.—At end of fourteen hours a red line extended all around the border of the membranous part of the abdominal parietes of the child. Chloroform was given, the membrane dissected off and the abdominal walls brought together, with through-and-through silkworm sutures. The umbilical vein was tied and cut under the liver. The urachus was patent from the bladder to the umbilicus. The urachus was closed by suture. A small Meckel's diverticulum was present and left untouched. Considerable difficulty was experienced in pulling the abdominal walls together over the liver and in replacing the intestines. The time of operation was one and a half hours. The baby left the operating table in fair condition, but died eight hours later.

Fourteen and a half months later the same woman gave birth to a healthy eight and a half pound boy. This second labor was normal, a L. O. A. position, and there was no deformity of child or cord.

This case emphasizes the fact that an abnormal position or presentation of a fetus should always cause us to suspect and search for some abnormality of fetus or mother's pelvis before considering it a mere chance abnormality. Most faulty presentations and positions have an ascertainable cause other than chance. In this case the presentation was cephalic:

1. Because the fetus was suspended by the short cord from the fundus of the uterus, and the cephalic end (from head to umbilicus) being longer than the caudal end (from umbilicus to coccyx) gravitated to the bottom of the uterus. Also the distance from sacrum to umbilicus is not long enough to allow the sacrum to reach the cervix, when the fetus is suspended on a five-inch cord.
2. The position was posterior, because in this position, with the placenta on the upper, anterior surface of the uterus, the short cord would reach furthest. In order to have allowed for an anterior position, with the placenta in this position, the cord would have had to wind around the fetus from umbilicus to back, which would have taken up so much of its length that the head could not have reached the cervix.
3. Hemorrhage during and between efforts at traction on the forceps was due to pulling on the placenta, causing some separation thereof.
4. Recoil of the head after traction on the forceps was due to the uterus assuming its original shape.
5. The fact that the head could be dragged to the vulva by the forceps with such a short cord was due to a partial inversion of the uterus during traction.
6. Uterine inertia was due to inability of the uterus to expel the child.
7. The statement of the midwife, if a correct observation, that the patient carried the child high in the abdomen and that there was no descent of the head until labor began, is also explained by the short cord.

A CASE OF SO-CALLED BOTTLE-MAKER'S CATARACT *

ROBERT VON DER HEYDT, M.D.
CHICAGO

Cases of bottle-maker's (often called glass-blower's) cataract, supposed to be due to prolonged exposure to excessive heat and bright light, are rarely seen except in localities where the industries that produce these changes are situated. This case is interesting on account of its occurring in one who has been a baker for many years, subjected daily to the continued high temperature of the bake-room.

History.—J. W., aged 41, has been working steadily as a baker for twenty-four years past. His sight, so he says, was always good. Three years ago he began to notice a gradual failure of vision, and now he cannot read the newspaper. He had not consulted anyone until Nov. 10, 1910, when I first saw him at my office.

Examination.—Vision, right eye, 15/80; left eye, 15/200; no improvement with glasses; urine negative for sugar and albumin; no signs of other intra-ocular disease. The lenses are absolutely clear, except in the posterior cortical zone, where there is situated a slightly irregular disk of opacity—half the size of the lens. The disk, especially by direct focal illumination, can be seen to have a well-defined and somewhat thickened, irregular border. Slight hazy opacities can be seen in the center of the disk, and the same to a less degree outside of same in the posterior cortical plane of the lens.

---

* Read and patient exhibited before the Chicago Ophthalmological Society, Dec. 19, 1910.

That this case is exactly similar in type to glass-blower's cataract is proved by the words of Herbert Parsons and Marcus Gunn, who, in 1908, visited some of the important glass-works in England for the Royal Society, to gather statistics of industrial diseases for the framing of the Workmen's Compensation Act. They say:

> Bottle-makers are subject to a form of cataract which appears to be characteristic, and is unlike other forms of cataract commonly observed. In its typical form there is a dense, well-defined disk of opacity in the center of the posterior cortex. Not infrequently slighter hazy opacities are seen around this posterior cortical disk.

Hirschberg describes it in a similar way, and in 1898 exhibited five cases of glass-blower's cataract. At the same time he drew attention to the peculiar color of the faces—the effect of heat on the skin. Most of the German literature on the subject seems to concede that heat is the factor that produces these changes in the lens and skin.

Weyl* mentions fire-workers, blacksmiths, puddlers, bakers and cooks as subject to this same change in the lens.

In a volume on industrial diseases, 1909, Greer says of bottle-maker's cataract: "It commences as a saucer-shaped opacity like a cobweb in appearance, and situated immediately within the posterior capsule of the lens."

The treatment which I am using is the method of von Pflugk and Verderau—instillations of 2 per cent. solution of potassium iodid, to be followed later by subconjunctival injections of the same. According to Hirschberg, these cases progress very slowly until 20/200 vision has been reached, when often a more rapid decline follows. When ready for operation they present a most favorable type for successful extraction.

34 Washington Street.

THE DIAGNOSTIC VALUE OF THE PARADOXIC REFLEX

AN ADDITIONAL ANATOMIC PROOF OF ITS PRACTICAL IMPORTANCE

ALFRED GORDON, M.D.
PHILADELPHIA

In December, 1904, I described[1] a new reflex under the name of paradoxic flexor reflex. I found it then present in cases the history of which pointed to organic diseases of the nervous system and especially of its motor tracts, and always associated with exaggerated knee-jerks. As is well known, Babinski's toe phenomenon is the clinical expression of a disease of the motor pathway.

The reflex can be elicited in the following manner: The patient may either lie on his back or sit on a chair with the feet (not the legs) on a stool. The feet must be slightly rotated externally; in this position complete relaxation of the muscles of the leg is obtained. The examiner must always place himself at the outer side of the leg; the thenar and hypothenar muscles of the right hand must be placed on the inner surface of the tibia of the patient and the fingers press deeply on the middle or the lower portion of the calf muscles. I say "deeply" because the pressure must be transmitted to the flexor muscles of the deep layer; sometimes pressure must be combined with lateral movements of the superficial muscles. If the reflex is present, extension of the great toe, or of all the toes, will be noticed. There is evidently no other muscle except the flexors that could be brought into display. The tibialis posticus, the peronei have an entirely different function from flexion or extension of the toes.

During my investigations I observed a peculiar relationship between these two reflexes. Babinski's sign was sometimes present and sometimes absent, but in the majority of my cases the paradoxic reflex was present on the side on which the Babinski sign was either absent or slight. It was present in those obscure cases in which the Babinski reflex was not obtainable.

My first series comprised thirty organic cases, in nineteen of which I observed that Babinski's sign and the paradoxic reflex showed a tendency to replace each other; viz., when one was slight, the other was marked and *vice versa*. There was a species of antagonism between the two reflexes.

My observations at the time of the first report were purely clinical. I had no anatomic proof to offer.

In December, 1908, I made a second report to the Philadelphia Neurological Society on fifty-eight cases. The diseases in which the reflex was studied were as follows: transverse myelitis, amyotrophic lateral sclerosis, hemiplegia, Jacksonian epilepsy, disseminated sclerosis, cerebrospinal syphilis and essential epilepsy. Here again I observed the same antagonism between the Babinski and paradoxic reflexes, viz., when one was present and pronounced, the other was absent; when one was mild, the other was pronounced. The latter fact was particularly conspicuous in seven cases of transverse myelitis: at first Babinski's sign was absent on one or both sides and the paradoxic reflex was present; two or three months later Babinski's sign made its appearance, and the paradoxic reflex completely disappeared or was faintly present. In one case of cerebrospinal syphilis in which the spinal symptoms were the most conspicuous, energetic mercurial treatment was instituted. The patient's mental functions, the ataxia and sphincters improved considerably. The knee-jerks, however, remained markedly exaggerated; ankle-clonus was present on one side, but Babinski's sign disappeared on one side and was only slightly preserved on the other; the paradoxic reflex remained intact and was easily obtainable.

As another illustration of the antagonistic relationship of the two reflexes may be mentioned six cases of Jacksonian epilepsy of the same series. In all there was paresis on the same side. When the examination was made immediately or shortly after the attacks, the knee-jerk was exaggerated on the affected side and the paradoxic reflex was easily elicited in all the cases, while Babinski's sign was in three cases only slightly present and in two others absent.

An analysis of all the facts observed and followed up led me to the conclusion that the paradoxic reflex is a valuable sign for diagnostic purposes at the beginning of an organic affection showing that the motor tract is being irritated; while Babinski's sign is of *inestimable* value in cases of a well-established *lesion of the motor* tract, the paradoxic reflex is a sign, to say the least, of a transient irritation or of a slight lesion of the same tract.

---

* Weyl: Handbuch der Arbeiterkrankheiten, 1908.

[1] Am. Med., 1904, viii, 971.

That a transient irritation may be the cause of the reflex can be seen among other facts, especially from the following case:

Case 1.—A lad of 12, in the course of typhoid fever, developed meningeal symptoms. He then had an attack of epileptiform convulsions on the right side which were followed by paralytic symptoms on the same side. I had an opportunity to examine him twice at an interval of two weeks. On both occasions the right knee-jerk was markedly exaggerated, there was no ankle-clonus and no Babinski sign, but the paradoxic reflex was present and easily elicited. The patient made a complete recovery; the paralytic symptoms, the increased knee-jerk and the paradoxic reflex disappeared.

My systematic study of sixty cases of paretic dementia[2] with reference to the reflexes of the lower extremities demonstrate the great rarity of the Babinski sign (on both sides in three cases and on one side in four cases), but the great frequency of the paradoxic reflex (in forty-two cases) in this disease. According to the pathologic reports in cases of paresis, the motor pathway is involved only to a very slight degree in the majority of instances. As Babinski's sign is usually the clinical expression of a well-defined degenerative lesion of the motor tract, the very moderate degree of pyramidal involvement will perhaps explain satisfactorily the rarity of Babinski's phenomenon in paresis. On the other hand, the presence of the paradoxic reflex in the largest number of my paretic cases finds its logical explanation in the slight degree of pyramidal involvement. This observation in paresis is therefore analogous to, if not identical with, the observation made in other organic nervous diseases, and tends to show, I believe, the correctness of my contention made in my earliest study of the significance of the paradoxic reflex.

From the clinical standpoint the diagnostic value of the paradoxic reflex appeared therefore to be established; it remained for me to corroborate it by anatomic proofs. That is to say, it was necessary to show that a real anatomic lesion was present in those cases in which during life the paradoxic reflex was the only or the most conspicuous sign and in which operative procedures were undertaken for this reason with satisfactory results so far as the finding of the lesion is concerned. Soon such opportunities presented themselves.

In 1906 and 1907, I had the opportunity to observe two cases.[3]

Case 2.—In this case, in which a localized hemorrhagic pachymeningitis was found in the right motor area, the paradoxic reflex was very distinct on the left together with a slightly exaggerated knee-jerk on the same side, but there was total absence of Babinski's and Oppenheim's toe phenomena and of ankle-clonus. The paradoxic sign was the most prominent symptom. When the blood was removed by the surgeon from the right hemisphere, the patient regained consciousness (he was deeply comatose before the operation), improved considerably and on the second day the patellar tendon reflex became normal and the paradoxic sign totally disappeared. Four days later, the same phenomena returned and the patient again became stuporous; the abnormal reflexes returned. The patient died two days later. Autopsy showed a reformation of the blood clot in the right hemisphere over the Rolandic area.

Case 3.—This concerns a man who complained of pain in the right side of the head in the same place where he received an injury six months previously. There was also marked mental hebetude and somnolence. The left knee-jerk was exaggerated and the paradoxic reflex was obtained with the greatest facility. There was no Babinski reflex, no Oppenheim sign, no ankle-clonus. The contrast between the flexion of the toes on the right side and extension on the left on pressure of the calf muscles was most striking. Trephining of the skull with exposure of the upper part of the Rolandic area was performed. As the opening was made, the cerebral tissue bulged out; it was evidently under high tension. The surgeon immediately closed it up. Rapidly the patient regained his intelligence; the somnolence and headache totally disappeared. At the end of forty-eight hours the paradoxic reflex became weaker and on the fourth day could no more be elicited. The patient was reexamined six weeks later; the paradoxic reflex and the increase of the knee-jerk were totally absent.

These two cases with the anatomic proofs corroborated in the most forceful manner the conclusions which I reached at the beginning of my studies from purely clinical observations, to wit, that the paradoxic reflex is a sign of value in the beginning of an organic affection of the motor system or in cases of its irritation, while Babinski's sign is of inestimable value in cases with a definitely established lesion of the motor pathway.

I wish to add a third anatomo-clinical case which, like the previous two, presents an exceedingly definite illustration of the diagnostic value of the paradoxical reflex and of its practical bearing.

Case 4.—*History.*—An Italian laborer, aged 23, of excellent health, during a quarrel sustained an injury over the left frontoparietal region at its upper level. He was struck with a piece of heavy iron. Laceration of the scalp ensued and a swelling of the parts of the size of a silver half dollar followed. There was no loss of consciousness, but mental hebetude and distinct motor aphasia developed. All the man could say was "yes" or "no." The patient came under my observation through the courtesy of Dr. I. Cortese about ten days after the trauma. On examination I found the above-mentioned hebetude and the motor aphasia. The patient could comprehend fairly well when spoken to, but was unable to articulate. Various objects were shown him and wrong names given them; when asked whether they were the proper names of the objects, he answered correctly "yes" or "no." Voluntarily, he could not articulate other words, or repeat them when spoken to him. There was no word-blindness or word-deafness.

Examination.—Physical examination showed good station and gait. The power of the right lower extremity was very slightly diminished, so slightly that the defect could be easily overlooked if the patient were not very closely examined. This was done by testing the resisting power of the thigh, leg and foot and comparing it with that of the corresponding segments on the opposite side. The right knee-jerk was also slightly more marked than the left; nevertheless the difference was distinct on repeated examinations. There was no ankle-clonus, no Babinski reflex, no Oppenheim sign. The paradoxic reflex was present on the right side in the most conspicuous manner; it could be elicited, with the greatest facility, during the entire fifteen days before the operation. The scalp presented the above-mentioned elevation over a small area at the uppermost portion of the left fronto-parietal region. The thickness of the lacerated surface prevented an exact determination of the condition of the underlying bony tissue; pressure provoked pain, however.

Treatment.—After the patient was placed in the Northwestern General Hospital his mental condition began to improve and the aphasia gradually disappeared. Both the paradoxic reflex and the slightly increased knee-jerk persisted with the greatest obstinacy and at no time could either Babinski or Oppenheim sign be elicited. The condition, in my opinion, therefore, indicated an involvement of the left motor area, probably only an irritation, but not a distinct lesion, in view of the absence of Babinski's sign. I advised an operation over the injured region of the scalp. Before operating an *x*-ray picture was taken, and a distinct involvement of the bony tissue was detected on the skiagraph. Dr. J. Thompson Schell performed an osteoplastic operation. The upper half of the Rolandic area, including the lacerated region, was exposed. A small fragment of the inner table of the skull was found imbedded in the dura, producing a subdural hemorrhage lying over the uppermost portion of the left motor area. The outer surface of the skull was intact. The opening of the lacerated dura was enlarged, the coagulated blood removed and the cortex exposed. The latter's surface was found intact; no laceration could be seen.

---

[2] Jour. Nerv. and Mental Dis., July, 1907.

[3] Rev. Neurol., No. 22, 1906; and Am. Jour. Med. Sci., August, 1907

Result.—The patient gradually improved and finally recovered. The mental hebetude completely disappeared. During the first two days the knee-jerk remained slightly exaggerated, but on the fourth day became normal. On the sixth day, the paradoxic reflex became fainter and on the twelfth day after the operation it could no more be elicited. It was interesting to observe its gradual diminution and disappearance and it was also interesting to notice its conspicuous presence on the morning before the operation and its gradual obliteration after the operation. The patient was subsequently seen by me several times during a period of two months and at no time could I detect the presence of an abnormal knee-jerk or of the paradoxic reflex.

This case, I believe, is the most striking illustration of my contention concerning the practical value of the reflex. Added to the first two cases published in 1906 and 1907,[3] it furnishes decisive anatomic proofs for the *a priori* deductions made from clinical observations. The reflex has its diagnostic value and deserves a place in nosology of the nervous system.

In conclusion, I may mention that a systematic investigation was made by me in 800 individuals free from diseases of the nervous system, also in 250 cases of functional nervous diseases and at no time was extension of the toes elicited by the method employed by me for the detection of the paradoxic reflex.

1430 Pine Street.

THE AUTOLYSIS OF THE CRYSTALLINE LENS

A PRELIMINARY REPORT

C. A. CLAPP, M.D.
BALTIMORE

In the study of traumatic cataract and the needling operation, I was struck with the very scant description of the manner in which the lens becomes opaque and the causes for its opacity and final absorption.

Parsons[1] states that after exposure of the lens fibers to the action of the aqueous they swell up, become opaque, protrude through the capsular wound, and finally break up in the usual manner, absorption being largely due to the leukocytes, which become swollen and filled with granules.

Schlösser[2] (1887) in an article on traumatic cataract, and Schirmer[3] (1889) have studied the microscopic changes very thoroughly, but without throwing much light on the cause of these changes.

Fuchs[4] states that the fibers swell up and become opaque through absorption of water; some are broken off and drop into the anterior chamber and are absorbed. But he also says that concussion without rupture of the capsule may cause the development of complete opacity of the lens. He, however, fails to state just why this occurs.

De Schweinitz[5] says that the opacity and liquefaction are explained by the action of the sodium chlorid of the aqueous on the globulin of the lens substance, as globulin is normally soluble in weak sodium chlorid solution. This theory was, I think, first suggested by Marcus Gunn in 1899 in the *Ophthalmic Review.*

In further search of the literature on the subject I have found no elaboration.

In order to understand the subject it is necessary to have a knowledge of the chemistry of both the aqueous and the crystalline lens.

Halliburton gives the composition of calves' aqueous as in Table 1.

TABLE 1.—COMPOSITION OF THE AQUEOUS

Water			986.87
Solids			13.13
Albumin		1.12	
Extractives		4.21	
Inorganic salts		7.70	
Sodium chlorid	6.89		

Thus it will be seen that it consists practically of normal saline solution with a trace of albumin and extractives.

The composition of the lens as given by Neumeister is set forth in Table 2.

TABLE 2.—COMPOSITION OF THE LENS

			Per cent.
Water			63.50
Solids			36.50
Albumins		35.00	
Insoluble albuminoids	17.00		
Crystalline (b)	11.00		
Crystalline (a)	6.80		
Albumin	0.20		
Fats		.29	
Lecithin		.23	
Cholesterin		.22	
Salts		.80	

It will be seen that the lens contains 35 per cent. of protein, the highest protein percentage of any tissue of the body. Of this 35 per cent. protein, 17 per cent. is in the form of an insoluble albuminoid which is insoluble in normal saline or water.

It is a true albumin and constitutes most of the lens fibers, its amount increasing from without inward in accordance with the increasing age of the lens fibers. The remaining protein consists of a small amount of serum albumin and two vitellins which are soluble in dilute saline or in water.

If these analyses are correct, we have great difficulties in explaining the foregoing theories.

I can hardly agree with Parsons' statement that most of these fibers are carried off by the leukocytes. In the first place, if there is no infection there should not be many polymorphonuclear leukocytes about, as they occur chiefly in inflammatory troubles; and secondly, it would not explain the traumatic cataract with absorption in those cases of concussion without rupture of the capsule.

Fuchs seems to keep on the safe side by simply stating that the fibers become opaque and are finally absorbed, and by giving no explanation for the cause of the concussion cataract.

De Schweinitz's promulgation of Marcus Gunn's suggestion is, if the chemistry be correct, entirely untenable. To be sure the (a) and (b) crystalline bodies would be dissolved out either by water or the aqueous, but the insoluble albuminoid which makes up the greater portion of the protein, and which occurs chiefly in the lens fibers, is insoluble in either the water or the saline.

It is easily seen from a study of the chemistry of the lens why it becomes opaque either after injury with the entrance of aqueous or even from concussion. In case of rupture of the capsule and entrance of the aqueous there would occur an immediate precipitation of this insoluble albuminoid, while the remaining portions

5. De Schweinitz: Diseases of the Eye, 1910.

That a transient irritation may be the cause of the reflex can be seen among other facts, especially from the following case:

Case 1.—*A lad of 12, in the course of typhoid fever, developed meningeal symptoms.* He then had an attack of epileptiform convulsions on the right side which were followed by paralytic symptoms on the same side. I had an opportunity to examine him twice at an interval of two weeks. On both occasions the right knee-jerk was markedly exaggerated, there was no ankle-clonus and no Babinski sign, but the paradoxic reflex was present and easily elicited. The patient made a complete recovery; the paralytic symptoms, the increased knee-jerk and the paradoxic reflex disappeared.

My systematic study of sixty cases of paretic dementia[2] with reference to the reflexes of the lower extremities demonstrate the great rarity of the Babinski sign (on both sides in three cases and on one side in four cases), but the great frequency of the paradoxic reflex (in forty-two cases) in this disease. According to the pathologic reports in cases of paresis, the motor pathway is involved only to a very slight degree in the majority of instances. As Babinski's sign is usually the clinical expression of a well-defined degenerative lesion of the motor tract, the very moderate degree of pyramidal involvement will perhaps explain satisfactorily the rarity of Babinski's phenomenon in paresis. On the other hand, the presence of the paradoxic reflex in the largest number of my paretic cases finds its logical explanation in the slight degree of pyramidal involvement. This observation in paresis is therefore analogous to, if not identical with, the observation made in other organic nervous diseases, and tends to show, I believe, the correctness of my contention made in my earliest study of the significance of the paradoxic reflex.

From the clinical standpoint the diagnostic value of the paradoxic reflex appeared therefore to be established; it remained for me to corroborate it by anatomic proofs. That is to say, it was necessary to show that a real anatomic lesion was present in those cases in which during life the paradoxic reflex was the only or the most conspicuous sign and in which operative procedures were undertaken for this reason with satisfactory results so far as the finding of the lesion is concerned. Soon such opportunities presented themselves.

In 1906 and 1907, I had the opportunity to observe two cases.[3]

Case 2.—In this case, in which a localized hemorrhagic pachymeningitis was found in the right motor area, the paradoxic reflex was very distinct on the left together with a slightly exaggerated knee-jerk on the same side, but there was total absence of Babinski's and Oppenheim's toe phenomena and of ankle-clonus. The paradoxic sign was the most prominent symptom. When the blood was removed by the surgeon from the right hemisphere, the patient regained consciousness (he was deeply comatose before the operation), improved considerably and on the second day the patellar tendon reflex became normal and the paradoxic sign totally disappeared. Four days later, the same phenomena returned and the patient again became stuporous; the abnormal reflexes returned. The patient died two days later. Autopsy showed a reformation of the blood clot in the right hemisphere over the Rolandic area.

Case 3.—This concerns a man who complained of pain in the right side of the head in the same place where he received an injury six months previously. There was also marked mental hebetude and somnolence. The left knee-jerk was exaggerated and the paradoxic reflex was obtained with the greatest facility. There was no Babinski reflex, no Oppenheim sign, no ankle-clonus. The contrast between the flexion of the toes on the right side and extension on the left on pressure of the calf muscles was most striking. Trephining of the skull with exposure of the upper part of the Rolandic area was performed. As the opening was made, the cerebral tissue bulged out; it was evidently under high tension. The surgeon immediately closed it up. Rapidly the patient regained his intelligence; the somnolence and headache totally disappeared. At the end of forty-eight hours the paradoxic reflex became weaker and on the fourth day could no more be elicited. The patient was reexamined six weeks later; the paradoxic reflex and the increase of the knee-jerk were totally absent.

These two cases with the anatomic proofs corroborated in the most forceful manner the conclusions which I reached at the beginning of my studies from purely clinical observations, to wit, that the paradoxic reflex is a sign of value in the beginning of an organic affection of the motor system or in cases of its irritation, while Babinski's sign is of inestimable value in cases with a definitely established lesion of the motor pathway.

I wish to add a third anatomo-clinical case which, like the previous two, presents an exceedingly definite illustration of the diagnostic value of the paradoxical reflex and of its practical bearing.

Case 4.—*History.*—An Italian laborer, aged 23, of excellent health, during a quarrel sustained an injury over the left frontoparietal region at its upper level. He was struck with a piece of heavy iron. Laceration of the scalp ensued and a swelling of the parts of the size of a silver half dollar followed. There was no loss of consciousness, but mental hebetude and distinct motor aphasia developed. All the man could say was "yes" or "no." The patient came under my observation through the courtesy of Dr. I. Cortese about ten days after the trauma. On examination I found the above-mentioned hebetude and the motor aphasia. The patient could comprehend fairly well when spoken to, but was unable to articulate. Various objects were shown him and wrong names given them; when asked whether they were the proper names of the objects, he answered correctly "yes" or "no." Voluntarily, he could not articulate other words, or repeat them when spoken to him. There was no word-blindness or word-deafness.

Examination.—Physical examination showed good station and gait. The power of the right lower extremity was very slightly diminished, so slightly that the defect could be easily overlooked if the patient were not very closely examined. This was done by testing the resisting power of the thigh, leg and foot and comparing it with that of the corresponding segments on the opposite side. The right knee-jerk was also slightly more marked than the left; nevertheless the difference was distinct on repeated examinations. There was no ankle-clonus, no Babinski reflex, no Oppenheim sign. The paradoxic reflex was present on the right side in the most conspicuous manner; it could be elicited, with the greatest facility, during the entire fifteen days before the operation. The scalp presented the above-mentioned elevation over a small area at the uppermost portion of the left fronto-parietal region. The thickness of the lacerated surface prevented an exact determination of the condition of the underlying bony tissue; pressure provoked pain, however.

Treatment.—After the patient was placed in the Northwestern General Hospital his mental condition began to improve and the aphasia gradually disappeared. Both the paradoxic reflex and the slightly increased knee-jerk persisted with the greatest obstinacy and at no time could either Babinski or Oppenheim sign be elicited. The condition, in my opinion, therefore, indicated an involvement of the left motor area, probably only an irritation, but not a distinct lesion, in view of the absence of Babinski's sign. I advised an operation over the injured region of the scalp. Before operating an *x*-ray picture was taken, and a distinct involvement of the bony tissue was detected on the skiagraph. Dr. J. Thompson Schell performed an osteoplastic operation. The upper half of the Rolandic area, including the lacerated region, was exposed. A small fragment of the inner table of the skull was found imbedded in the dura, producing a subdural hemorrhage lying over the uppermost portion of the left motor area. The outer surface of the skull was intact. The opening of the lacerated dura was enlarged, the coagulated blood removed and the cortex exposed. The latter's surface was found intact; no laceration could be seen.

[2] Jour. Nerv. and Mental Dis., July, 1907.

[3] Rev. Neurol., No. 22, 1906; and Am. Jour. Med. Sci., August, 1907.

Result.—The patient gradually improved and finally recovered. The mental hebetude completely disappeared. During the first two days the knee-jerk remained slightly exaggerated, but on the fourth day became normal. On the sixth day, the paradoxic reflex became fainter and on the twelfth day after the operation it could no more be elicited. It was interesting to observe its gradual diminution and disappearance and it was also interesting to notice its conspicuous presence on the morning before the operation and its gradual obliteration after the operation. The patient was subsequently seen by me several times during a period of two months and at no time could I detect the presence of an abnormal knee-jerk or of the paradoxic reflex.

This case, I believe, is the most striking illustration of my contention concerning the practical value of the reflex. Added to the first two cases published in 1906 and 1907,[3] it furnishes decisive anatomic proofs for the *a priori* deductions made from clinical observations. The reflex has its diagnostic value and deserves a place in nosology of the nervous system.

In conclusion, I may mention that a systematic investigation was made by me in 800 individuals free from diseases of the nervous system, also in 250 cases of functional nervous diseases and at no time was extension of the toes elicited by the method employed by me for the detection of the paradoxic reflex.

THE AUTOLYSIS OF THE CRYSTALLINE LENS

A PRELIMINARY REPORT

C. A. CLAPP, M.D.
BALTIMORE

In the study of traumatic cataract and the needling operation, I was struck with the very scant description of the manner in which the lens becomes opaque and the causes for its opacity and final absorption.

Parsons[1] states that after exposure of the lens fibers to the action of the aqueous they swell up, become opaque, protrude through the capsular wound, and finally break up in the usual manner, absorption being largely due to the leukocytes, which become swollen and filled with granules.

Schlösser[2] (1887) in an article on traumatic cataract, and Schirmer[3] (1889) have studied the microscopic changes very thoroughly, but without throwing much light on the cause of these changes.

Fuchs[4] states that the fibers swell up and become opaque through absorption of water; some are broken off and drop into the anterior chamber and are absorbed. But he also says that concussion without rupture of the capsule may cause the development of complete opacity of the lens. He, however, fails to state just why this occurs.

De Schweinitz[5] says that the opacity and liquefaction are explained by the action of the sodium chlorid of the aqueous on the globulin of the lens substance, as globulin is normally soluble in weak sodium chlorid solution. This theory was, I think, first suggested by Marcus Gunn in 1899 in the *Ophthalmic Review.*

In further search of the literature on the subject I have found no elaboration.

In order to understand the subject it is necessary to have a knowledge of the chemistry of both the aqueous and the crystalline lens.

Halliburton gives the composition of calves' aqueous as in Table 1.

TABLE 1.—COMPOSITION OF THE AQUEOUS

Water			986.87
Solids			13.13
Albumin		1.12	
Extractives		4.21	
Inorganic salts		7.70	
Sodium chlorid	6.89		

Thus it will be seen that it consists practically of normal saline solution with a trace of albumin and extractives.

The composition of the lens as given by Neumeister is set forth in Table 2.

TABLE 2.—COMPOSITION OF THE LENS

			Per cent.
Water			63.50
Solids			36.50
Albumins		35.00	
Insoluble albuminoids	17.00		
Crystalline (b)	11.00		
Crystalline (a)	6.80		
Albumin	0.20		
Fats		.29	
Lecithin		.23	
Cholesterin		.22	
Salts		.80	

It will be seen that the lens contains 35 per cent. of protein, the highest protein percentage of any tissue of the body. Of this 35 per cent. protein, 17 per cent. is in the form of an insoluble albuminoid which is insoluble in normal saline or water.

It is a true albumin and constitutes most of the lens fibers, its amount increasing from without inward in accordance with the increasing age of the lens fibers. The remaining protein consists of a small amount of serum albumin and two vitellins which are soluble in dilute saline or in water.

If these analyses are correct, we have great difficulties in explaining the foregoing theories.

I can hardly agree with Parsons' statement that most of these fibers are carried off by the leukocytes. In the first place, if there is no infection there should not be many polymorphonuclear leukocytes about, as they occur chiefly in inflammatory troubles; and secondly, it would not explain the traumatic cataract with absorption in those cases of concussion without rupture of the capsule.

Fuchs seems to keep on the safe side by simply stating that the fibers become opaque and are finally absorbed, and by giving no explanation for the cause of the concussion cataract.

De Schweinitz's promulgation of Marcus Gunn's suggestion is, if the chemistry be correct, entirely untenable. To be sure the (a) and (b) crystalline bodies would be dissolved out either by water or the aqueous, but the insoluble albuminoid which makes up the greater portion of the protein, and which occurs chiefly in the lens fibers, is insoluble in either the water or the saline.

It is easily seen from a study of the chemistry of the lens why it becomes opaque either after injury with the entrance of aqueous or even from concussion. In case of rupture of the capsule and entrance of the aqueous there would occur an immediate precipitation of this insoluble albuminoid, while the remaining portions

2. Schlösser: Experimental Studies on Traumatic Cataract, 1887.
3. Schirmer: Arch. f. Ophth., 1889.
4. Fuchs: Text-Book of Ophthalmology, 1908
5. De Schweinitz: Diseases of the Eye, 1910.

would be soluble and could be carried off by the circulation of the aqueous. In cases of concussion without rupture of the capsule, there undoubtedly occurs some rupture of the lens fibers, and then this insoluble albuminoid is brought into contact with the lens lymph which acts in the same manner as the aqueous in precipitating the albuminoid.

But what is the factor which causes the solution of this albuminoid so that it can pass off in the circulation?

As we have known for several years that most of the organs and tissues of the body show autolytic activity under favorable conditions, we believe that this autolytic action also takes place in the lens substance after the rupture and breaking up of the lens fibers. There is also quite a possibility that there is some ferment in the aqueous which hastens this action. It is more probable, however, that the aqueous serves its chief purpose in carrying off the liquefied lens substance. Therefore, in order either to prove or to disprove our theories, the following experiments were carried out, using calves' eyes as the working material. They were enucleated at the abattoir and transported immediately to the laboratory and kept on ice until used, which was always within six hours after enucleation.

Nov. 1, 1909, I received thirty calves' eyes and drew off the aqueous with a sterile hypodermic needle. The lenses were removed and macerated, then diluted with normal saline solution, so as to make a dilute solution of lens albumin of about 1 per cent. This was agitated so as to make as nearly a homogeneous suspension of the insoluble portions as possible, and 5 c.c. were measured into three test-tubes. To the first were added 5 c.c. of the aqueous solution. To the second were added 5 c.c. of the boiled aqueous. To the third were added 5 c.c. of normal saline solution. These were stoppered tightly and placed in an incubator at 36 C. and allowed to remain for twenty-two days.

Chloroform and toluol were added to prevent bacterial action. They were then removed and the amount of soluble nitrogen was determined in each tube. They were precipitated by the action of heat and acetic acid, filtered and washed, and the amount of nitrogen determined in the filtrate by Kjeldahl's method, which consists of digesting with concentrated sulphuric acid and copper sulphate and distilling the remains, after rendering strongly alkaline, into a measured amount of tenth-normal sulphuric acid and titrating the excess of the acid.

By this procedure I obtained the results shown in Table 3.

TABLE 3

No. 1.—5 c.c. lens albumin
5 c.c. aqueous
= 2.1675 c.c. N/10 H_2SO_4
No. 2.—5 c.c. lens albumin
5 c.c. boiled aqueous
= 1.9675 c.c. N/10 H_2SO_4
No. 3.—5 c.c. lens albumin
5 c.c. normal salt
= 0.8175 c.c. N/10 H_2SO_4

By this experiment it appears that the boiling of the aqueous has some inhibitory effect on its action on the lens albumin. It also appears that the aqueous either increases this process, or at least hastens it, because as will be seen, there is over twice as much soluble nitrogen in No. 1, which was combined with the unboiled aqueous, as in No. 3, in which there was only salt solution.

On account of lack of aqueous these experiments were not done with a control, so that the results are open to more criticism than they would otherwise be. All other experiments along similar lines with equal quantities of lens and aqueous were spoiled so that I lack confirmatory evidence, which I hope I shall be able to supply shortly.

Nov. 8, 1909, I started another series in the following manner:

Twenty calves' lenses were macerated with the accompanying aqueous, 15 c.c., and the whole made up to 500 c.c. with normal salt solution. Chloroform and toluol were added to prevent bacterial changes.

The preparation was then placed in a tightly stoppered flask and set in an incubator at 36 C., a measured amount being removed from time to time and the soluble nitrogen being determined by precipitating with heat and acetic acid and doing the Kjeldahl test on the filtrates as in the preceding experiment, with results given in Table 4.

TABLE 4.—VARIATIONS IN SOLUBLE NITROGEN AS DETERMINED BY HEAT AND ACETIC ACID

Date	N/10 H_2SO_4, c.c. Required by Soluble Nitrogen in 100 c.c.
11/ 8/09	4.8000
11/16/09	2.6750
11/23/09	3.5875
11/30/09	4.3375
12/ 7/09	3.9625
12/15/09	3.8375
1/ 5/10	4.0875
2/17/10	5.9625
3/17/10	5.8375
5/23/10	8.1175
10/25/10	8.9125

The autolytic material was now set at room temperature until October 25.

As will be seen by a glance at these figures there was a considerable lessening of the soluble nitrogen immediately after starting the process, after which, with practically one exception, a gradual rise until the quantity was nearly twice that of the original amount.

This initial decrease could be explained by the possibility of a reversible action of the ferment and a building up instead of a tearing down, as is seen in some other instances in physiologic chemistry, notably some of the fat ferments.

The influence of the small amount of aqueous in this experiment was, I believe, almost *nil*, as I will show in the following experiment a similar picture without the presence of any aqueous.

Nov. 18, 1909, twenty calves' lenses were macerated and made up to 500 c.c. with normal saline solution. Chloroform and toluol were added and placed in an incubator at 36 C., being placed in a tightly stoppered flask to prevent evaporation; 20 c.c. was removed from time to time and the precipitable protein removed by Abeles' method, which is as follows:

Fifty c.c. of absolute alcohol, 2.5 gm. zinc acetate, and 50 c.c. of the fluid are mixed and allowed to stand ten minutes and then filtered through a filter moistened with alcohol; the residue is rubbed up in a mortar several times and filtered; the zinc is precipitated with 20 per cent. sodium carbonate solution; this is filtered, acidulated with acetic acid, evaporated and a Kjeldahl test done on the filtrate.

This method is claimed to give more accurate results than the heat and acetic acid method. By the use of this method I obtained the following results:

TABLE 5.—VARIATIONS IN SOLUBLE NITROGEN BY ABELES' METHOD

Date	N/10 H_2SO_4, c.c. Required by Soluble Nitrogen in 100 c.c.
11/18/09	1.8375
11/22/09	2.5875
11/29/09	2.4625
12/ 6/09	2.5875
12/14/09	2.3275
1/ 3/10	2.4625
2/14/10	3.4625
3/17/10	4.4625
5/23/10	7.3675
10/20/10	7.3675

Set at room temperature until October 20.

In this and the preceding series, double estimations were made and when there was a variation the average of the results were taken.

It will be seen, as in the preceding experiment, that there was very little change for the first three months and then there was such a pronounced change that one could hardly believe it to be accidental.

Here, as in the preceding series, there was little or no action while the material was at room temperature, from May to October, 1910.

Whether this was due to the slightly lowered temperature I cannot say. Neither can I say whether the increase in soluble nitrogen would have continued, as I had insufficient material to continue the experiment.

The tryptophan reaction was negative in both of these last experiments, on Dec. 11, 1910, showing that there was no very active ferment at work which would split up the amido-acids. Both preparations were tested for bacterial growth Dec. 12, 1910, by inoculating slant agar, with negative results.

If further investigation confirms my preliminary findings, then I think that it is safe to say that when the lens fibers are broken up they undergo autolytic changes. Whether this is increased by the action of some specific enzyme in the aqueous or whether it is due entirely to autolysis, it is difficult to say. If this be a ferment, then what is its source? Is it produced through the breaking up of the lens fibers, or is it derived from the circulating lymph? These questions I cannot answer.

These results coincide nicely with the facts as we know them. The lens of the young is much more easily liquefied and carried off, from the fact that there is less of the insoluble albuminoid present and the enzymes are all very active. In the aged, on the contrary, there is a much larger amount of the insoluble portion and all of the enzymes are relatively weak.

In closing I wish to thank Dr. E. L. Whitney for his many kind suggestions, and for the use of his private laboratory and apparatus at the Baltimore Medical College.

412 Cathedral Street.

TESTS OF THE VIRULENCE OF DIPHTHERIA BACILLI *

B. L. ARMS, M.D., and E. MARION WADE, B.A.
Bacteriological Laboratory of the Boston Board of Health
BOSTON

Many times the laboratory worker is requested to test the virulence of diphtheria bacilli, especially in cases running for a long time, or in those occurring in institutions, and as we have had many interesting results from these tests we present some of them for consideration.

Our laboratory has always made virulence tests, on request either from the Board of Health or from the attending physician, the procedure being to isolate either by the streak-out method or surface seeding. For the former a series of eight or ten tubes is used, a fresh tube being inoculated from the incubated one; then, after sterilizing the needle, another from the freshly inoculated one, and so on through the series, taking from the first tube to the second, from the second to the third, etc., sterilizing the needle after inoculating each tube. In that way isolated colonies may be found on the later ones, as of course a smaller number of organisms is carried over each time. For the surface-seeding method five tubes are used, those being selected which contain a fair amount of water of condensation. This is rubbed over the surface in order to insure an even distribution at the proper time. Inoculation is made directly into the water of condensation of the first tube, the needle is sterilized, and a loopful is carried into the water in the second tube; sterilization and inoculation being repeated throughout the series. The tubes are then laid down at the proper angle to cause the water to flow over the surface of the serum and allowed to remain for from two to five minutes, when they are taken up carefully and put into the incubator in the upright position. After incubation isolated colonies are "fished" and planted on serum and in sugar-free broth, and a microscopic examination is also made.

If there is no particular need for haste, or, in cases in which the organisms are very few, we sometimes make serum and microscopic examinations only, inoculating several colonies one above the other on a single serum tube, thereby making a great saving in the amount of media used; for many times we "fish" from twenty to forty colonies from a single series, especially from long-standing cases, the broths being made from the serum tubes after incubation.

These are incubated for forty-eight hours and pigs inoculated subcutaneously, using 0.5 per cent. of the body weight. The reaction may be local or general, or, as is usual in positive cases, both, and is generally present the following day, although a negative report is never given until forty-eight hours after the inoculation.

The virulence of morphologically typical diphtheria bacilli (Wesbrook's A C D) varies, not only in different cases but in different strains from the same case, from those absolutely non-virulent to those which cause death within thirty-six hours.

This was first brought to our notice in December, 1906, when a series of six pigs was inoculated, each with a different strain isolated from the same release culture.

In order to hasten the report one strain was inoculated at the end of the twenty-four hours and this proved virulent, the pig being so nearly dead on the second day that it was chloroformed.

The other five strains were all incubated for forty-eight hours and the difference in their virulence was very marked:

1. This was the pig previously mentioned.
2. This pig died on the eighth day, the reaction being local and general.
3. This pig died on the second day.
4. This pig showed a very slight local reaction on the second day, which increased slightly during the next week, but at no time was there a marked reaction. This pig was kept under observation for six weeks, complete recovery resulting.
5. This pig died on the ninth day.
6. In this instance there was a slight local reaction at the end of twenty-four hours which became more marked daily for some time and there was a slough surrounding the point of inoculation, the pig dying at the end of six weeks.

All of the above strains, grown fifteen hours on serum, were of Wesbrook's A A1 types. A rush of work prevented further tests at this time but an interesting problem had been presented.

Nov. 9, 1907, three pigs were inoculated with three strains isolated from a release culture, two dying within forty-eight hours and the other showing no symptoms; in order to rule out a possible difference in the resistance of the pigs we kept the cultures and eleven days later inoculated the surviving pig, and a new one to serve as a control, with the avirulent strain and at the

---

* Read before the Society of American Bacteriologists, at Ithaca, N. Y., Dec. 28-30, 1910.

same time another pig with one of the virulent strains; the first two showed a very slight local reaction the following day and the one receiving the virulent strain showed a marked reaction but lived three weeks from the date of inoculation, dying at that time. On the twenty-second, or two days after the last inoculation, the two pigs receiving the avirulent strain were reinoculated—the original pig with the virulent strain and the control with the avirulent; the original pig developed marked local and general symptoms, dying on the eleventh day from the last inoculation, and the control never showed anything beyond a slight local reaction, from which a complete recovery was made within a few days.

Since this time we have endeavored to make inoculations from several strains from each case, although until recently we have not had a similar case. Aug. 14, 1910, three pigs were inoculated with three strains isolated from a release culture, one of which was virulent and two avirulent.

On several occasions we have been requested to make retests on cases running a protracted course, but it has been our experience that when it has been demonstrated that a virulent organism has caused the condition the virulence remains to the last, and two cases are presented:

Case 1.—Duration from first positive culture to release by two successive negatives, seventy-six days. December 29, 1906, two pigs were inoculated, one dying on the second and one on the third day; December 30, one pig, which died on the second day. Jan. 17, 1907 (this was the last positive culture), two pigs were inoculated, both dying three days later.

Case 2.—Culture was first taken Jan. 10, 1910, and a positive diagnosis returned; all symptoms disappeared within ten days, but the case ran until March 30, when the patient was allowed by the board to go into the country. Virulence tests, made January 28, February 13, and March 26, were all positive.

In general we have found the organisms persisting after a clinical case of diphtheria virulent, but the non-clinical carriers usually harbor non-virulent organisms, an example of this being presented before this society last year.[1] One of the conclusions drawn from that work was as follows: "Where virulent diphtheria bacilli are present, as shown by outbreaks of the disease, cultural tests of all contacts, and isolation of those showing positive cultures, is a duty owed to the community."

An illustration of the truth of this conclusion was demonstrated recently in an institution in which there are about 150 boys. Oct. 8, 1910, the first positive case was reported; another on the sixteenth, one on the twentieth, one November 3 and five on the fourth. This opened the eyes of those in charge and on November 6 seventy cultures were taken from the two cottages in which cases had occurred, fourteen of which were positive; on the eighth 136 cultures were submitted, of which six were positive. The clinical cases had been removed before the general culture taking began, so the last twenty positives were non-clinical cases; but of six cases on which virulence tests were made three were positive, from four to six strains being tried from all cases as follows:

Boy 1.—Six strains inoculated November 14, all positive, the pigs dying within forty-eight hours.

Boy 2.—Seven strains inoculated November 14, all positive, two pigs dying on the second day, two on the third, and three on the fourth.

Boy 3.—Seven strains inoculated November 16, all positive, two pigs dying on the second, four on the third, and one on the fifth day.

Boy 4.—Five strains inoculated November 16, and one December 11 from another culture; all negative.

Boy 5.—Three strains inoculated November 21 and two December 11; all negative.

Boy 6.—Four strains inoculated November 21, all negative; one strain December 1, the pig dying on the second day; two strains December 5 and ten strains December 12, being negative.

It occurred to us that possibly there might be a cause for the variation in virulence in the source of the primary infection. Accordingly the school hospital was consulted and we found that the first four boys, or three with virulent and one with avirulent organisms, came from the same cottage and the remaining two came from two other cottages where there had been no clinical diphtheria. Thus it will be seen that all the boys who were harboring virulent organisms came from a single cottage, and from this cottage most of the clinical cases had been taken, and that also a carrier of non-virulent organisms came from the same cottage. Boy 1, three days after the culture taking, became a clinical case and was sent to the contagious hospital, the others being isolated on the institution grounds.

It is interesting to note that those cases which showed a positive virulence at all times cleared up more quickly than the others. The last positive cultures from Boys 2 and 3 were taken twenty-one and twenty days, respectively, after the primary one, the others still being positive three weeks later.

While working on these institutional cases we had a few positive cases from another institution where they had a single clinical case, and the virulence was tested on two of them, one being the clinical case, and the other, one of the exposed children. From the clinical case five strains were inoculated, four of them being positive and one negative; of the positive pigs three died on the second and one on the third day; from the other case all three were positive, the pigs dying within forty-eight hours.

One other case occurred at the same time. A boy at home had clinical diphtheria and both his mother and brother had positive cultures. The mother's throat cleared within six days but the brother's persisted. A virulence test was made from the primary culture of the brother, who was never a clinical case, two strains being tested, one killing the pig on the third day, the other being non-virulent.

CONCLUSIONS

1. Clinical diphtheria is caused by virulent diphtheria bacilli.
2. As a rule, following clinical diphtheria, the organisms retain their virulence as long as they persist.
3. As a rule, virulent and avirulent bacilli are not found in the same case, but, as these cases do occur, several strains should be tested before they are reported non-virulent.
4. In diphtheria outbreaks a large percentage of the "carriers" harbor virulent organisms, although such carriers may develop no symptoms whatever.
5. Cultures should be taken from all contacts before terminating quarantine in all cases of diphtheria.

TREATMENT OF SINUS AND MIDDLE-EAR DISEASE WITH THE VACUUM-PUMP

J. A. PRATT, M.D.
AURORA, ILL.

Careful study of the nose impresses one with the fact that the sinuses play a greater part in its troubles than we have ever imagined.

Many headaches which oculists formerly ascribed to eyestrain are now found to be caused by sinus trouble. As a rule, sinus headaches are easily diagnosed, as they are intensified by lowering the head, but frequently there are obscure cases in which diagnosis is difficult; it is well, therefore, in patients complaining of continuous or interrupted pain in the head, not increased by eye work, to make a thorough examination of the sinuses. Frequently the most painstaking examination fails to reveal pus at the natural openings of the sinuses. If the ostia are not patulous and the confined pus or secretion lacks the pressure necessary to force its way out, the physician is apt to miss the diagnosis of sinusitis and to ascribe the headache to some other cause. It is in such cases, that application of the vacuum-pump for a few minutes demonstrates the sinusitis by relieving the headaches. This is particularly true in acute cases, especially before they become purulent, and in my opinion the vacuum-pump should be used as a regular routine measure for diagnostic purposes in patients with these vague head symptoms.

In middle-ear diseases in which there is a patulous tube, the vacuum-pump is of inestimable value, as the secretions of the middle ear, antrum and even of the mastoid, if there are patulous openings, are easily drawn into the throat, the natural drainage spot. With suppurating otitis media with perforation the condition of the tube may be ascertained by inflation.

A suction-pump should never be applied to the external meatus, because while by this means the secretions are drawn from the middle ear and its adjacent cavities, one is also apt to draw germs and secretion from around the pharyngeal opening of the Eustachian tube up into the middle ear, and it is possible to reinfect or doubly infect that cavity. By covering a small cork with a piece of soft tubing and plugging the external meatus, after all available secretions have been swabbed out, and then applying the vacuum-pump to the nose the secretions are sucked out by the way that Nature intended they should go.

While we cannot tell positively the function of the different sinuses, we know that they must be well ventilated, and that the hypermoistened air and what little secretion is present are drained into the nose and pharynx by the vacuum pressure caused by the air as it rushes to and fro in the nasopharyngeal passage. In using the vacuum-pump we are simply magnifying Nature's method of emptying these spaces, and by this increase in power we are able to overcome partial stenosis of the ducts and openings leading from these sinuses to the upper air tract.

The first principle of good surgery is to drain if pus be present; and by use of the vacuum-pump, we are applying to these chambers this great principle. Relieving Nature of this extra work is frequently the turning-point in a cure.

Surgery should not be abandoned. Every nose should be made as nearly normal as possible so that there will be proper ventilation of the nasal chamber. All pressure should be removed from the openings of the sinuses; then with the vacuum treatment the radical operation can frequently be avoided. Unless there are urgent symptoms, such as pain and necrosis, months instead of weeks, as recommended by Ballenger, should be devoted to this line of treatment, for all operators know that the radical operation is not followed by prompt recovery, and that frequently months of post-operative treatment are necessary. Whether the patient should have a radical operation or not must be decided by the physician. Knowing that pus under pressure is very virulent and destructive to tissue, we should at once relieve these cavities when they contain pent-up secretions, and this the vacuum-pump enables us to do.

By using the vacuum-pump we do not leave solutions in a sinus, nor do we infect cavities, as we are apt to do in the washing-out treatment.

Very little has been written on this subject and Ballenger's is the only book I have seen that mentions the vacuum method. The technic of using the pump is very simple. The patient's nasal cavity is thoroughly cleaned, and then sprayed with a 2 per cent. cocain solution to contract the tissues and render the sinus openings more patulous. After the pump is attached to the water faucet, the patient is instructed to close one nostril and insert the nasal tip in the other; by swallowing, the soft palate is then raised and closes off the nasopharyngeal space, while the suction of the pump holds the velum tightly in place. As soon as the patient feels the suction he should open his mouth, allowing the tongue to lie perfectly relaxed and breathing through the mouth.

In my experimental work along this line, I find that ten minutes of actual suction is sufficient to empty the sinuses and to give their membranes a stimulating hyperemia.

When the discharge is very profuse, I give the treatment twice a day, and if necessary, I give the instrument to the patient for home treatment.

A report of a few cases may be of interest:

Case 1.—Mr. S., aged 42, had chronic frontal sinus trouble for some years. When first seen some years ago, a deviating septum was operated on, and the anterior third of both middle turbinates removed, thus curing the right sinus by establishing good drainage. The left sinus still discharges, as the patient will come to the office only when in pain, caused by the retained secretion during nasal congestion. A treatment by the vacuum-pump relieves the symptoms for weeks. This is one of the many cases every physician has in which the patient is too busy to be cured.

Case 2.—Miss B., aged 18, had had headache for three days, which was worse when the head was lowered. The nasal mucous membrane was congested; there was very little secretion. After five minutes' application of the pump the pain was entirely relieved. Treatments were given for three consecutive days; there was no pain or discomfort after the first treatment.

Case 3.—Mrs. S., aged 45, had had intense frontal headache for six weeks; it was slightly worse on the left side. Glasses were fitted by two different physicians but with no relief of pain. Pain was continuous night and day; at times it was so great that the patient threatened to end her life if not relieved. The pain was exaggerated on leaning forward, and by jars. There was no discharge from nose or throat. The nasal examination showed no hypertrophies and the only discharge found was a very small drop of pus at the nasal opening at the left posterior ethmoid sinus. The vacuum-pump relieved the pain in two minutes, when a mucopurulent mass was blown from the left nostril; after the ten minutes' treatment there was absolutely no pain; a slight sense of fulness returned the next day but without pain. The patient was not seen for twelve days; there was no further complaint.

Case 4.—Miss H., aged 16, a schoolgirl, came to be examined for glasses as her head had been aching for a week. Sinusitis was diagnosed: three treatments with vacuum pump effected a cure.

Case 5.—Mr. H., aged 40, electrician, had previously been fitted with glasses. He has an extreme deviation of the septum to the left completely blocking the left nostril, and during the past year he twice set date for submucous operation. He complained of photophobia and pain in and over the left eye, radiating to the occiput. The pupil was contracted; there was no nasal discharge, and headache was not particularly increased by leaning forward. The pain was severe enough to awaken the patient. The pupil was dilated and he was sent home. On the following day there was no relief of symptoms, but the patient was relieved at once by application of the vacuum-pump, and there was no return of symptoms after the fourth treatment. The pump certainly corrected this diagnosis and as I look back I can recall many cases that would have been cleared up by this little instrument.

Case 6.—Miss H., aged 25, has had progressive deafness with tinnitis and fulness of the ears for two years. There was partial stenosis of the nasal passage, which was relieved by operative means, and then inflations employed with benefit up to a certain point. After inflation, the patient would soon complain of stuffiness and noise. The vacuum-pump has started this patient on the road to recovery, as the serous secretion is now sucked from the middle ear; the sense of stuffiness and noise rarely returns and the hearing is now steadily improving, while before it was at a standstill.

There are great possibilities in these cases in which there is hypersecretion of the middle-ear and its accessory cavities. Many physicians are undoubtedly using the vacuum-pump, but in my clinical wandering I have not come across them. Future reports along these lines will be interesting.

A CASE OF PRIMITIVE OBSTETRICS

L. WEINSTOCK, M.D.
GERMANTOWN, PA.

History.—On Jan. 1, 1911, at 1:30 p. m., I was called to a negress, iii-para, age 22, unmarried, a domestic in a boarding house who had given birth to a boy at 3:30 a. m. of the same day under the following circumstances: Thinking herself pregnant for but seven months, she had made no arrangements for the birth of this child, as she had had twins about a year and a half ago, both children dying soon after birth. On Dec. 31, 1910, at 11 p. m., while alone in the house, she experienced a sudden pain in the abdomen which made her "double up." It soon passed off, and she thought it was simply cramp. In a short time pains began again, and she suspected that they were labor pains. After four and a half hours a boy was born. She waited till the placenta was born, and with scissors cut the cord about six inches from the umbilicus, and did *not* tie the cord which was still attached to the child. Washing herself as well as she could, and wrapping the child up in a blanket, she went to sleep. Next morning at 6:30 a. m. she rose, dressed, prepared breakfast for the family, did her other work, and then told her mistress what had happened early in the morning. She then wrapped all her bloody linen around the placenta, placed the bundle in a suit case, wrapped the child in some blankets, and went home on foot, a distance of six squares. Reaching home, which by the way was the home of the father, she went to bed and called me.

Examination.—I found the patient to be a fairly well-developed young woman, of apparent good health. Temperature was 98.6 F., pulse 65, respiration 18. Vaginal examination showed a slight median tear of the perineum, but the uterus was in normal condition following delivery. She was given a uterine douche. The child was fully developed, about 8 pounds in weight, and showed no marks or deformities. After giving the child a bath, I tied the cord about one and a half inches from the umbilicus, and cut off the rest. This procedure was, I think, not absolutely necessary, as the cord was absolutely bloodless, but was done for sake of precaution.

Subsequent History.—The mother never had a temperature above 98.8 F., or a pulse rate above 70 during her six days in bed. She got out of the bed on Jan. 6, 1911, and went back to her position. The child is doing well, and seems in no way concerned as to the attention he received when he entered this world.

The long time the child was attached to the placenta, a period, so far as the mother can guess, of ten minutes, probably saved it from hemorrhage. This case seems to emphasize the point that in a normal case the less the attending physician does the better it will be for the mother.

44 West Chelten Avenue.

A METHOD OF STAINING GRANULAR CASTS AND OTHER TUBE PRODUCTS

H. B. ERDMAN, M.D.
WERNERSVILLE, PA.

Since it is often desirable to stain and mount tube-casts for preservation, the following method is suggested as being simple and easily carried out, and at the same time showing distinctly many features difficult to recognize in the unstained specimen:

Sediment the fresh urine in a centrifuge: pour off the supernatant urine, and fill the tube with 0.4 per cent. sodium chlorid solution. Gently shake the deposit, centrifuge, pour off the solution, and repeat the washing, this time centrifuging till the sediment forms a dense clump at the bottom of the tube.

Slowly pour off the solution, invert the tube and allow it to drain for a few moments; the sediment will remain in the point of the tube.

With a long pipette transfer a small drop of sediment to a cover-glass, gently spread with a fine platinum wire loop, and dry in air. The spread must be thin.

Treat for three minutes with a 5 per cent. aqueous solution of mercuric chlorid. Wash thoroughly in water.

Stain for five minutes with a fresh mixture of equal parts of the following solutions: methylene blue, 0.3 per cent. aqueous solution: fuchsin, 0.02 per cent. aqueous solution; wash in water, dry, and mount in balsam.

To demonstrate fat, stain the fixed spread for five minutes with a solution of Sudan III in 70 per cent. alcohol. Wash in water, and apply the double stain as before. Mount in glycerin or glycerin jelly.

Mucin and chromatin stain violet to indigo, granular casts and protoplasm stain from pink to dark red, waxy casts stain bright red and fat globules bright orange.

One washing may suffice when the urine contains a very small amount of sediment. The stains may be used singly, first staining with fuchsin, washing in water and counter-staining with methylene blue.

Leukocytes and epithelial cells stain distinctly, the protoplasm of renal epithelium usually taking a dark red color, that of squamous epithelium a light pink. Red blood-cells may show a pale salmon color. Mucinous products are distinguished chiefly as filaments, agglutinations, showing their structure by longitudinal or spiral striations, and homogeneous casts. These forms merge into each other, there are no sharp dividing lines. They are probably not of much significance when not accompanied by granular casts.

Granular casts stain red and are thus more easily found than in the unstained sediment. Homogeneous casts staining red may be found in connection with granular casts. They are frequently of high density and refraction, assuming a waxy character. Epithelial cells may be embedded in mucinous, granular or waxy material.

New and Nonofficial Remedies

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED BY THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION. THEIR ACCEPTANCE HAS BEEN BASED LARGELY ON EVIDENCE SUPPLIED BY THE MANUFACTURER OR HIS AGENT AND IN PART ON INVESTIGATION MADE BY OR UNDER THE DIRECTION OF THE COUNCIL. CRITICISMS AND CORRECTIONS ARE ASKED FOR TO AID IN THE REVISION OF THE MATTER BEFORE PUBLICATION IN THE BOOK "NEW AND NONOFFICIAL REMEDIES."

THE COUNCIL DESIRES PHYSICIANS TO UNDERSTAND THAT THE ACCEPTANCE OF AN ARTICLE DOES NOT NECESSARILY MEAN A RECOMMENDATION, BUT THAT, SO FAR AS KNOWN, IT COMPLIES WITH THE RULES ADOPTED BY THE COUNCIL.

W. A. PUCKNER, SECRETARY.

COMPRESSED OXYGEN: Oxygenium compressum.—Compressed oxygen is gaseous oxygen, O_2, in a compressed state.

Compressed oxygen is a colorless, odorless and tasteless gas, slightly soluble in water and neutral to ordinary indicators. The gas is not inflammable but supports combustion much more vigorously than does air. Ignited carbon, sulphur, phosphorus and heated iron burn with an intense light in the gas. It colors colorless reduced indigo—carmine blue.

Compressed oxygen should be neutral toward litmus and when passed through an aqueous solution of silver nitrate no turbidity should be produced.

No color should be produced when 4 liters of the gas are passed through water containing potassium iodide and starch solution.

Not more than an opalescence should be produced when 4 liters of the gas are passed through an aqueous solution of barium hydroxide.

When 4 liters of the gas are passed through an aqueous solution of sodium hydroxide, then over heated platinum, and finally through an aqueous solution of barium hydroxide, no turbidity should be produced in the latter. When shaken in a gas burette with an alkaline solution of pyrogallol at least 94 per cent. of the gas should be absorbed.

Actions and Uses.—Compressed oxygen is administered for the purpose of relieving difficult respiration in cases of mechanical hindrance to the ingress of air to the lungs.

Dosage.—It is inhaled from a mouth piece attached to the cylinder.

TUBERCULIN PREPARATIONS (SEE N. N. R. (1911), P. 196)

Farbwerke vorm. Meister, Lucius & Bruening, Hoechst a. M., Germany (Victor Koechl & Co., New York).

Triturated Tubercle Bacilli.—Used for the preparation of an agglutinating liquid for the detection of agglutinins in the blood serum of tuberculous patients. The bacilli are rubbed in a mortar with 0.8 per cent. sodium chloride solution containing 0.5 per cent. phenol and centrifugalized for a short time; the preparation is to be diluted 1 to 10,000 before using. Marketed in bottles containing 0.1 Gm. triturated tubercle bacilli.

Spinal Anesthesia and Shock.—The principal agencies in the production of surgical shock and collapse are those which make a sudden and deep impression on the central nervous system or the large sympathetic ganglia through the medium of the sensory nerves. Experimental researches have shown that if we block the passage of such impulses by means of a local anesthetic drug injected into the large nerve trunks leading from the part, or into the dural sac, we safeguard the patient against shock. Spinal anesthesia, therefore, prevents shock by blocking off the centripetal impulses passing to the nervous centers. To obtain a perfect result by this method it is essential to produce a complete block, otherwise shock to a greater or lesser degree will result.—E. C. Ryall, in the *Practitioner*.

Therapeutics

ASCARIS LUMBRICOIDES

ROUND WORM

Many years ago it was a common belief among members of the medical profession that large numbers of children suffered from worms. More recently, the presence of these parasites as the cause of unpleasant symptoms has been in a measure neglected by the profession. While mothers, nurses and friends have been quick to suggest worms as the cause of noticeable symptoms, physicians have ridiculed the idea with the result that many a physician has been humiliated by having exhibited to him a worm, which had been passed by a child, after he had expressed the opinion that there were no worms. The fact is that worms are sufficiently prevalent among children for the physician to bear in mind the possibility of obscure symptoms being due to this cause.

In the case of the *Oxyuris vermicularis*, or thread worm, the presence of itching about the anus is so common and so conspicuous a symptom that there is little excuse for overlooking the presence of the parasite, but with the *Ascaris lumbricoides*, or round worm, the case is different. One or more of these worms may be present in the intestine without giving rise to any symptom of sufficient importance to attract the attention of either the parent or the physician. This renders it all the more important that the physician should be on the lookout and consider the possibility of the presence of this parasite in any child, who for a considerable period suffers from indefinite symptoms for which no clear explanation can be found.

The round worm is considered by some to be the most common of the intestinal parasites found in the human subject, although others believe that the pin worm is more common. The round worm is of a reddish or brownish color, about ¼ inch in diameter, the size of a goose quill. The male varies in length from 4 to 8 inches, the female from 6 to 12 inches. The male is the more curved, and the female the straighter. It has been estimated that the genital tubes of a large, mature female may contain 60,000,000 eggs. The eggs after having been passed from the intestine are exceedingly tenacious of vitality, which may be retained even for two or three years. These worms live, also, in the intestinal canal of cattle and hogs, and the eggs may be conveyed with the excrement of these animals to fields where vegetables are cultivated, and either on such vegetables, which are not carefully cleaned, or in water which is consumed in the fields or at the table, the ova may be taken into the stomach of the human subject.

The eggs are destroyed by boiling, and may be removed by filtration, so that people who use distilled or filtered water need have little fear of becoming infected with the round worm. After having been taken into the stomach, in the course of one, two, or three weeks, the worm is hatched out and then continues to live, ordinarily, in the upper part of the small intestine. From this, its usual habitat, it may travel into the stomach, and is sometimes expelled from this organ by vomiting. Sometimes it comes into the throat, from which it may be removed by the fingers. Rarely it enters the larynx, where it may produce asphyxiation; or it may go into the trachea and produce gangrene of the lungs. Sometimes it enters the nose, and in rare instances has passed through the Eustachian tube into the middle ear. From the intestine it may also enter the bile ducts. The intestine may contain a single worm, but generally there are several, perhaps six or eight, and over a hundred have been found. When there are very many, they may collect together into a mass, and may cause intestinal obstruction.

As has been stated, worms may be present in the intestine and give rise to no noticeable symptoms. Probably many of the symptoms which have been attributed to worms are not really due to them, but to some other condition.

The symptoms which are due to their presence are: transient pains in the abdomen of varying severity; changes in the appetite, either impairment of appetite or ravenous appetite; occasional attacks of diarrhea, the movements sometimes having a mucous character; sometimes nausea and vomiting; distention of the abdomen; loss of flesh; and itching about the anus and about the nose. Nervous symptoms are frequently attributed to presence of worms in the intestine. These may be restlessness, especially during sleep, irritability, choreic movements and, in rare instances, epileptic convulsions of greater or less severity.

The presence of worms is definitely determined by finding the worm in the feces. This is most likely to be possible after the patient has taken a cathartic. A more certain way of making the diagnosis, but one which, of course, is more troublesome, is to examine microscopically the solid residue obtained by filtering the liquid feces. If worms are present, their eggs will be found in the fecal matter.

Associated with the worm is a peculiar, disagreeable odor, which is characteristic, and which is believed by some to belong to a toxic product produced by the worm, which toxin gives rise to symptoms referable to the nervous system.

Treatment directed toward the removal of the worm should not be commenced until a positive diagnosis has been made. The drugs most frequently used to extirpate this parasite are santonin and spigelium. The one in most common use and most effective is santonin, though it is a drug that may readily cause poisoning and, therefore, should be used with caution, especially in young children.

As is so well understood in the treatment for the extirpation of a tapeworm, the emptier the upper part of the intestine is, the less food or nutriment the worms have had, the better will they partake of the drug that stupefies or kills them. After they are stupefied, ordinary catharsis will eradicate them. The younger the child, naturally the less severe must be the treatment.

Taking a child 5 years old as a type, it should be given a cathartic dose of a laxative at night, such as an aromatic fluidextract of cascara or the aromatic tincture of rhubarb. The next morning the child should receive for breakfast only a cup of weak tea or a cup of clam broth, just so that it will feel it has had something to eat. Then the specific should be used, either santonin or spigelium. If the child is weak, or much younger than 5 years, spigelium should be the drug relied on.

For a child 5 years old:

℞	Gm. or c.c.		
Fluidextracti spigeliæ	50	or	fl. ℥ii
Fluidextracti sennæ	25		fl. ℥i

M. et Sig.: One-half a teaspoonful, in water, every hour for three doses.

If it is thought best to use the more powerful drug, santonin, it may be administered as follows:

℞	Gm. or c.c.		
Santonini	0|30	or	gr. v
Hydrargyri chloridi mitis	0|20		gr. iii
Sacchari lactis	3|		gr. xlv

M. et fac chartulas 10.
Sig.: A powder, in water, every hour for three doses.

If the above does not move the bowels in four hours after the first dose of the vermifuge, some other cathartic must be given, such as castor oil, or such portion of a seidlitz powder as is advisable for the age of the patient. In an hour after the last dose of either the spigelia or santonin, the little patient may have a good meal. At any time during the treatment if the child seems weak, a little brandy stimulation should be given.

Wormseed oil (*oleum chenopodii*) has long been used to eradicate this worm, and is more or less efficient. The dose is about 5 drops, several times repeated. A cathartic should follow. When this oil is used, it may be given on a lump of sugar or in a teaspoonful of granulated sugar.

Whatever the treatment, it is advisable to repeat it in three days, and again in a week. After the catharsis is complete, in the latter part of the day of treatment, a catheter should be inserted through the rectum, well up through the sigmoid, and a colon wash should be given with a small amount of warm saline solution, stronger with salt than the physiologic saline. This will wash out many of the eggs of the worms that have not been removed by defecation.

While the above treatment seems more or less elaborate and looks almost like a surgical proposition, it is not good sense to dally with a patient who has these worms. They must be eradicated, if possible.

It should not be forgotten that an unhealthy condition of the intestinal tract is usually associated with the presence of the round worm, and a chronic catarrh of the intestine is conducive to their welfare and encourages their growth and persistence. Hence we should always, after the above treatment, carefully regulate the diet and give such medication, bismuth and soda perhaps, or magnesium, as will cause normal movements of the bowels and cure the chronic catarrh of the upper intestine.

SANTONICA, U. S. P.

LEVANT WORMSEED

This is also known as Aleppo, Alexandria or European wormseed. It is a small shrub, about a foot in height (*Artemisia pauciflora*), which grows in Europe and Asia, and the part used is the "dried, unexpanded flower-heads" (U. S. P.). These flower-heads are very small, and are of a pale, greenish-brown color, and have a camphoraceous odor and a bitter taste. They contain from 1 to 2 per cent. of santonin, about 2 per cent. of a volatile oil, artemisin, a resin and a gum.

SANTONIUM, U. S. P.—SANTONIN

Description.—Santonin is a neutral principle obtained from santonica, and is "the inner anhydrid or lactone of santonic acid" (U. S. P.). Santonin undergoes changes if exposed to the light. It occurs in shining, colorless prisms, has no odor, is not readily soluble, but if held long in the mouth gives a bitter taste.

Action.—Santonin is not irritant, very slowly dissolves in the stomach and intestine, and but a small amount, ordinarily, is absorbed. If much is absorbed, it causes nervous phenomena, one of which is yellow sight, zanthopsia, i. e., objects look yellow. This is a harmless condition, and may last for from several hours to a day. It may be due to an action on the cerebrum or on the retina, as the fluids of the eye are not colored. If a poisonous amount is absorbed, the nervous system is seriously affected and the circulation is depressed. There may be also some kidney irritation. If there is much absorbed, the urine becomes yellow, which in the presence of an alkali is changed to red. A bloody-appearing urine after santonin has been administered should be treated with acid, which will change the color to yellow. This would differentiate the santonin product from blood. After the administration of santonin, it is not unusual to have increased frequency of urination, and sometimes irritability of the bladder.

Fortunately, but a small portion of the drug is absorbed, and this is absorbed as sodium santoninate. The major part of the drug ingested passes through the intestine unassimilated and stimulates the intestine somewhat, causing increased peristalsis. It has not been determined whether santonin stupefies the round worm, or whether it sets up an intoxication of the worm which kills it. At any rate, the round worm, under the influence of santonin and a cathartic, is expelled, sometimes dead, sometimes alive.

Toxic Action.—If a poisonous amount of santonin is absorbed (and if santonin remains long in the stomach and intestine such an amount is readily absorbed) the hands and feet become cold, the face pale, there may be profuse perspiration and a weak pulse, typical collapse symptoms. On the other hand, there may be dizziness, tremblings, and convulsions, followed by coma, and death from failure of the respiration. The treatment is rapid evacuation of the stomach and bowels, the administration of strychnin, coffee and whiskey or brandy if there is circulatory failure, and the application of dry heat to the body. If the nervous symptoms are much in evidence, and especially if there are convulsions, inhalations of chloroform should be given, and then later the collapse symptoms treated.

Therapy.—There is only one legitimate use for santonin, and that is to remove the *Ascaris lumbricoides*, or round worm of the intestine. It has been recommended and used for incontinence of urine in children, in epilepsy, and in some diseases of the retina and optic nerve, but there is no justification for such use of this drug.

Administration.—It has been stated that an oil would cause this drug to be more readily absorbed, and therefore, poisoning could more readily take place. This seems not to be true. In fact, castor oil administered with, or perhaps better an hour or two after the santonin, is a preventive of its absorption.

The dose for a child 5 years old is 0.03 gram (½ grain), well combined with a small dose of calomel. This dose may be repeated once an hour for three times, and then not repeated for at least three days.

Sodium santoninate is more soluble, and therefore more rapidly absorbed than santonin, and hence is more dangerous than santonin, and should not be used.

It is needless to state, after the description of the above toxicology, that santonin should not be given carelessly to young children. In fact, it should not be sold by a druggist except through the prescription of a physician. Serious poisoning not infrequently occurs.

Official Preparation.—*Trochisci santonini*, troches of santonin, contain 3 per cent. of santonin, with sugar, tragacanth and a small quantity of orange flower water. Each troche contains 0.03 gram (½ grain). The dose for a child 5 years old would be one tablet, thoroughly chewed up, every hour for three doses, this followed by a cathartic.

SPIGELIA, U. S. P.

PINK-ROOT

Description.—Spigelia, genitive spigeliæ (*Spigelia marilandica*) is a plant of the states around or near the Potomac River. It is variously known as the Maryland, Carolina or Indian pink; often also called worm weed and American worm-root. The plant grows to a height of one or two feet, and the part official is the dried rhizome and roots. It contains a volatile alkaloid, spigelin, a bitter principle, a volatile oil, resins, tannin, wax, fat and a gum.

Action.—This drug has no special action externally. When taken internally it causes, ordinarily, no systemic effects. If it remains long in the intestine not accompanied by or soon followed by a cathartic, enough may be absorbed to be depressant to the nervous system and circulation. In exceedingly rare instances it might cause irritation to the nervous system and could cause death. In the intestine it exerts a stupefying or toxic effect on the round worm, and catharsis completes the extirpation of the parasite. The drug passes out of the body principally by the intestines, without any absorption having taken place.

Toxic Action.—It is exceedingly rare for any toxic effect to occur from spigelia. If, however, it remains long in the alimentary tract, enough could be absorbed to cause muscle and circulatory weakness, impairment of vision, dilatation of the pupil, possibly delirium and convulsions, with general paresis and coma. Such action from this drug, however, is exceedingly rare, and could only occur when the mistake was made of not combining in some way the administration of the drug with a cathartic. The treatment would be evacuation of the stomach and bowels, cardiac stimulants, especially strychnin, and surrounding the body with dry heat.

Therapy.—The only therapeutic use for spigelia is to promote the removal from the intestine of the round worm, and occasionally to aid in the removal from the rectum of the pin worm.

Official Preparation.—*Fluidextractum spigeliæ.* The single dose for a child of 10 years is 5 c.c. (1 fluidram), a teaspoonful.

Administration.—The fluidextract is the best preparation of this drug, and it is used combined in the same prescription with the fluidextract of senna, with one part of the fluidextract of senna to two parts of the fluidextract of spigelia, and the dose for a child five years of age would be about one-half a teaspoonful of the mixture, every hour for three doses, and then if the bowels do not move in two or three hours, some brisk purgative should be given.

For efficient action of any anthelmintic the bowels should be well moved some hours previous to the administration of the anthelmintic, and any nourishment given during the period of activity of the treatment should be either simple bouillon or weak tea.

It should be remembered that spigelia does not kill round worms, but stupefies them; consequently, if good cathartic action does not soon occur after the administration of the spigelia in combination with a laxative, a brisk cathartic, as a saline, should be administered, else the worms revive and are again difficult to remove.

through the Eustachian tube into the middle ear. From the intestine it may also enter the bile ducts. The intestine may contain a single worm, but generally there are several, perhaps six or eight, and over a hundred have been found. When there are very many, they may collect together into a mass, and may cause intestinal obstruction.

As has been stated, worms may be present in the intestine and give rise to no noticeable symptoms. Probably many of the symptoms which have been attributed to worms are not really due to them, but to some other condition.

The symptoms which are due to their presence are: transient pains in the abdomen of varying severity; changes in the appetite, either impairment of appetite or ravenous appetite; occasional attacks of diarrhea, the movements sometimes having a mucous character; sometimes nausea and vomiting; distention of the abdomen; loss of flesh; and itching about the anus and about the nose. Nervous symptoms are frequently attributed to presence of worms in the intestine. These may be restlessness, especially during sleep, irritability, choreic movements and, in rare instances, epileptic convulsions of greater or less severity.

The presence of worms is definitely determined by finding the worm in the feces. This is most likely to be possible after the patient has taken a cathartic. A more certain way of making the diagnosis, but one which, of course, is more troublesome, is to examine microscopically the solid residue obtained by filtering the liquid feces. If worms are present, their eggs will be found in the fecal matter.

Associated with the worm is a peculiar, disagreeable odor, which is characteristic, and which is believed by some to belong to a toxic product produced by the worm, which toxin gives rise to symptoms referable to the nervous system.

Treatment directed toward the removal of the worm should not be commenced until a positive diagnosis has been made. The drugs most frequently used to extirpate this parasite are santonin and spigelium. The one in most common use and most effective is santonin, though it is a drug that may readily cause poisoning and, therefore, should be used with caution, especially in young children.

As is so well understood in the treatment for the extirpation of a tapeworm, the emptier the upper part of the intestine is, the less food or nutriment the worms have had, the better will they partake of the drug that stupefies or kills them. After they are stupefied, ordinary catharsis will eradicate them. The younger the child, naturally the less severe must be the treatment.

Taking a child 5 years old as a type, it should be given a cathartic dose of a laxative at night, such as an aromatic fluidextract of cascara or the aromatic tincture of rhubarb. The next morning the child should receive for breakfast only a cup of weak tea or a cup of clam broth, just so that it will feel it has had something to eat. Then the specific should be used, either santonin or spigelium. If the child is weak, or much younger than 5 years, spigelium should be the drug relied on.

For a child 5 years old:

℞	Gm. or c.c.		
Fluidextracti spigeliæ	50|	or	fl. ʒii
Fluidextracti sennæ	25|		fl. ʒi

M. et Sig.: One-half a teaspoonful, in water, every hour for three doses.

If it is thought best to use the more powerful drug, santonin, it may be administered as follows:

℞	Gm. or c.c.		
Santonini	0|30	or	gr. v
Hydrargyri chloridi mitis............	0|20		gr. iii
Sacchari lactis	3|		gr. xlv

M. et fac chartulas 10.
Sig.: A powder, in water, every hour for three doses.

If the above does not move the bowels in four hours after the first dose of the vermifuge, some other cathartic must be given, such as castor oil, or such portion of a seidlitz powder as is advisable for the age of the patient. In an hour after the last dose of either the spigelia or santonin, the little patient may have a good meal. At any time during the treatment if the child seems weak, a little brandy stimulation should be given.

Wormseed oil (*oleum chenopodii*) has long been used to eradicate this worm, and is more or less efficient. The dose is about 5 drops, several times repeated. A cathartic should follow. When this oil is used, it may be given on a lump of sugar or in a teaspoonful of granulated sugar.

Whatever the treatment, it is advisable to repeat it in three days, and again in a week. After the catharsis is complete, in the latter part of the day of treatment, a catheter should be inserted through the rectum, well up through the sigmoid, and a colon wash should be given with a small amount of warm saline solution, stronger with salt than the physiologic saline. This will wash out many of the eggs of the worms that have not been removed by defecation.

While the above treatment seems more or less elaborate and looks almost like a surgical proposition, it is not good sense to dally with a patient who has these worms. They must be eradicated, if possible.

It should not be forgotten that an unhealthy condition of the intestinal tract is usually associated with the presence of the round worm, and a chronic catarrh of the intestine is conducive to their welfare and encourages their growth and persistence. Hence we should always, after the above treatment, carefully regulate the diet and give such medication, bismuth and soda perhaps, or magnesium, as will cause normal movements of the bowels and cure the chronic catarrh of the upper intestine.

SANTONICA, U. S. P.

LEVANT WORMSEED

This is also known as Aleppo, Alexandria or European wormseed. It is a small shrub, about a foot in height (*Artemisia pauciflora*), which grows in Europe and Asia, and the part used is the "dried, unexpanded flower-heads" (U. S. P.). These flower-heads are very small, and are of a pale, greenish-brown color, and have a camphoraceous odor and a bitter taste. They contain from 1 to 2 per cent. of santonin, about 2 per cent. of a volatile oil, artemisin, a resin and a gum.

SANTONIUM, U. S. P.—SANTONIN

Description.—Santonin is a neutral principle obtained from santonica, and is "the inner anhydrid or lactone of santonic acid" (U. S. P.). Santonin undergoes changes if exposed to the light. It occurs in shining, colorless prisms, has no odor, is not readily soluble, but if held long in the mouth gives a bitter taste.

Action.—Santonin is not irritant, very slowly dissolves in the stomach and intestine, and but a small amount, ordinarily, is absorbed. If much is absorbed, it causes nervous phenomena, one of which is yellow sight, zanthopsia, i. e., objects look yellow. This is a harmless condition, and may last for from several hours to a day. It may be due to an action on the cerebrum or on the retina, as the fluids of the eye are not colored. If a poisonous amount is absorbed, the nervous system is seriously affected and the circulation is depressed. There may be also some kidney irritation. If there is much absorbed, the urine becomes yellow, which in the presence of an alkali is changed to red. A bloody-appearing urine after santonin has been administered should be treated with acid, which will change the color to yellow. This would differentiate the santonin product from blood. After the administration of santonin, it is not unusual to have increased frequency of urination, and sometimes irritability of the bladder.

Fortunately, but a small portion of the drug is absorbed, and this is absorbed as sodium santoninate. The major part of the drug ingested passes through the intestine unassimilated and stimulates the intestine somewhat, causing increased peristalsis. It has not been determined whether santonin stupefies the round worm, or whether it sets up an intoxication of the worm which kills it. At any rate, the round worm, under the influence of santonin and a cathartic, is expelled, sometimes dead, sometimes alive.

Toxic Action.—If a poisonous amount of santonin is absorbed (and if santonin remains long in the stomach and intestine such an amount is readily absorbed) the hands and feet become cold, the face pale, there may be profuse perspiration and a weak pulse, typical collapse symptoms. On the other hand, there may be dizziness, tremblings, and convulsions, followed by coma, and death from failure of the respiration. The treatment is rapid evacuation of the stomach and bowels, the administration of strychnin, coffee and whiskey or brandy if there is circulatory failure, and the application of dry heat to the body. If the nervous symptoms are much in evidence, and especially if there are convulsions, inhalations of chloroform should be given, and then later the collapse symptoms treated.

Therapy.—There is only one legitimate use for santonin, and that is to remove the *Ascaris lumbricoides,* or round worm of the intestine. It has been recommended and used for incontinence of urine in children, in epilepsy, and in some diseases of the retina and optic nerve, but there is no justification for such use of this drug.

Administration.—It has been stated that an oil would cause this drug to be more readily absorbed, and therefore, poisoning could more readily take place. This seems not to be true. In fact, castor oil administered with, or perhaps better an hour or two after the santonin, is a preventive of its absorption.

The dose for a child 5 years old is 0.03 gram (½ grain), well combined with a small dose of calomel. This dose may be repeated once an hour for three times, and then not repeated for at least three days.

Sodium santoninate is more soluble, and therefore more rapidly absorbed than santonin, and hence is more dangerous than santonin, and should not be used.

It is needless to state, after the description of the above toxicology, that santonin should not be given carelessly to young children. In fact, it should not be sold by a druggist except through the prescription of a physician. Serious poisoning not infrequently occurs.

Official Preparation.—*Trochisci santonini,* troches of santonin, contain 3 per cent. of santonin, with sugar, tragacanth and a small quantity of orange flower water. Each troche contains 0.03 gram (½ grain). The dose for a child 5 years old would be one tablet, thoroughly chewed up, every hour for three doses, this followed by a cathartic.

SPIGELIA, U. S. P.

PINK-ROOT

Description.—Spigelia, genitive spigeliæ (*Spigelia marilandica*) is a plant of the states around or near the Potomac River. It is variously known as the Maryland, Carolina or Indian pink; often also called worm weed and American worm-root. The plant grows to a height of one or two feet, and the part official is the dried rhizome and roots. It contains a volatile alkaloid, spigelin, a bitter principle, a volatile oil, resins, tannin, wax, fat and a gum.

Action.—This drug has no special action externally. When taken internally it causes, ordinarily, no systemic effects. If it remains long in the intestine not accompanied by or soon followed by a cathartic, enough may be absorbed to be depressant to the nervous system and circulation. In exceedingly rare instances it might cause irritation to the nervous system and could cause death. In the intestine it exerts a stupefying or toxic effect on the round worm, and catharsis completes the extirpation of the parasite. The drug passes out of the body principally by the intestines, without any absorption having taken place.

Toxic Action.—It is exceedingly rare for any toxic effect to occur from spigelia. If, however, it remains long in the alimentary tract, enough could be absorbed to cause muscle and circulatory weakness, impairment of vision, dilatation of the pupil, possibly delirium and convulsions, with general paresis and coma. Such action from this drug, however, is exceedingly rare, and could only occur when the mistake was made of not combining in some way the administration of the drug with a cathartic. The treatment would be evacuation of the stomach and bowels, cardiac stimulants, especially strychnin, and surrounding the body with dry heat.

Therapy.—The only therapeutic use for spigelia is to promote the removal from the intestine of the round worm, and occasionally to aid in the removal from the rectum of the pin worm.

Official Preparation.—*Fluidextractum spigeliæ.* The single dose for a child of 10 years is 5 c.c. (1 fluidram), a teaspoonful.

Administration.—The fluidextract is the best preparation of this drug, and it is used combined in the same prescription with the fluidextract of senna, with one part of the fluidextract of senna to two parts of the fluidextract of spigelia, and the dose for a child five years of age would be about one-half a teaspoonful of the mixture, every hour for three doses, and then if the bowels do not move in two or three hours, some brisk purgative should be given.

For efficient action of any anthelmintic the bowels should be well moved some hours previous to the administration of the anthelmintic, and any nourishment given during the period of activity of the treatment should be either simple bouillon or weak tea.

It should be remembered that spigelia does *not kill* round worms, but stupefies them; consequently, if good cathartic action does not soon occur after the administration of the spigelia in combination with a laxative, a brisk cathartic, as a saline, should be administered, else the worms revive and are again difficult to remove.

ANIMAL EXPERIMENTATION

The Bureau for the Protection of Medical Research of the American Medical Association has had prepared, by experts in the several fields, pamphlets on the relation of animal experimentation to practical medicine and surgery.[1] The latest pamphlet and one of the best and, we believe, most effective of the series, on "Some Characteristics of Antivivisection Literature," is by Dr. W. B. Cannon, the chairman of the bureau.[2] In it the nature of antivivisection methods is discussed after an extensive study of antivivisection pamphlets, leaflets and letters to the daily press.

The antivivisectionists have always made much of the testimonials of physicians in their behalf. Examination of the list of physicians whom they quote gives an instructive revelation of the methods of the agitators. Sir Charles Bell, dead nearly seventy years, secured the final proof of his greatest discoveries by experiments on animals done a hundred years ago; he is quoted as opposed to present methods of medical research. The address of Dr. Henry J. Bigelow, delivered forty years ago and based on experience in pre-anesthesia days, is quoted without reference to a later letter in which he admitted the utility of experimentation and objected sharply to the failure of antivivisectionists to discriminate between painful experiments and those in which pain is minimized. Dr. Lawson Tait, known generally as "a man of wild statements," whose denunciation of Koch, Pasteur and Lister has been widely quoted, is shown to have "enjoyed being in a minority," which led him to champion many lost causes.

Other physicians, whose opinions are quoted in antivivisection pamphlets, are as follows: Dr. Charles Clay, born in 1801, "interested in geology and archeology and collector of fossils." Dr. Charles Spooner, born in 1806, veterinary surgeon. Dr. John Elliotson, born in 1791, mesmerist, and founder of a mesmeric hospital. Dr. J. E. Garretson, born eighty-two years ago, and Dr. Elizabeth Blackwell, born eighty-nine years ago. Sir William Fergusson, M.D., born more than a century since, said to be ill-advised in some expressions of opinion, "especially in matters requiring more knowledge of physiology and hygiene than he possessed." Charles Bell-Taylor (dead in 1909, aged 80) who originated the widely quoted sentence: "Pasteur does not cure hydrophobia, he gives it"; and who, ignoring our great debt to animals for the medicines that induce sleep, for all those that give us local freedom from pain, for physostigmin, amyl nitrite, epinephrin, and many others, told his antivivisection admirers that experiments on animals have yielded us no knowledge of drugs. Sir Richard Owen, M.D., comparative anatomist and zoologist, born in 1804. Dr. John Abernethy, who *died* in 1831. J. J. Garth Wilkinson, born ninety-eight years ago, holder of an *honorary* M.D. degree, poet, mystic, expositor and editor of Swedenborg, author of "Improvisations of the Spirit," etc.

Information regarding the living "physicians and surgeons of greatest eminence" was obtained from the little autobiographies in "Who's Who." Dr. Arabella Kenealy sets herself down as novelist and contributor to magazines, author of "Molly and Her Man of War," "Some Men are Such Gentlemen," and other volumes. Dr. W. Gordon-Stables describes himself as novelist, journalist, professional writer for twenty-four years, author of 136 books and serial novels; "In the Dashing Days of Old" and "The Pirates' Gold" are cited as examples. Dr. W. R. Hadwen is secretary of the British Union for the Abolition of Vivisection, public advocate of the repeal of the vaccination acts and the prohibition of experiments on animals; is engaged in reform movements relating to temperance, food, hygiene, sanitation, education, and burial laws; he finds his recreation in changing his occupation. Dr. Edward Berdoe, born seventy-four years ago, reports himself as a writer; author of Browning studies, "Browning and the Christian Faith," "A Browning Primer," "The Browning Encyclopedia," "*The Biographical and Historical Notes* to Browning's Complete Works," and several other books; also editor of the *Zoophilist*. Dr. Josiah Oldfield is given as a lawyer, and senior physician to the Lady Margaret Fruitarian Hospital, strong advocate of the fruitarian diet; author of "Flesh-Eating as a Cause of Consumption," "Butchery and Its Horrors," and other volumes. Dr. J. D. Buck, 72 years old, is said to be president of the Theosophical Society of Ohio, author of "Nature and Aims of Theosophy," "Mystic Masonry," "Why I am a Theosophist." Dr. Stephen Townsend is given as novelist, surgeon, and actor, on the stage for years, playing prominent rôles in "Sowing the Wind," "Slaves of the Ring," "Black Tulip," and others.

This completes the list of "eminent" physicians and surgeons who have opposed vivisection, concerning whom any characterization whatever was found—the rest are not of sufficient importance to be mentioned in any of the dictionaries or cyclopedias of biography searched through for information. And this is the array of medical experts who have denounced the method of investigation which, according to Osler, "did more, in the half-century between 1850 and 1900, to emancipate medicine from the routine and thraldom of authority than all the work of all the physicians from the days of Hippocrates to Jenner."

[2] Critic and Guide, February, 1911

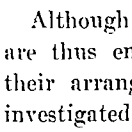
Dr. Cannon next examines some of the accounts of experiments cited in antivivisection pamphlets, and shows how persistently the opponents of medical research have refused to correct serious misstatements regarding the work of medical investigators. Fifteen years have passed since Dr. H. P. Bowditch pointed out the absurdity of the charge that supreme "agony" was caused by stimulating a piece of nerve separated from the central nervous system—the slander is still being distributed. Ten years have passed since Dr. W. W. Keen laid bare in The Journal instances of repeated interpolations, mistranslations, and garbled, inaccurate accounts of experiments in a single antivivisection publication—the New York Antivivisection Society is now circulating literature in which the deceptions and evil insinuations are still retained. Two years ago, Dr. F. S. Lee again indicated publicly definite instances in which the antivivisectionists were deluding the public—in pamphlets now sent broadcast these misrepresentations are still present, unchanged. Two years are not enough for the antivivisectionists to learn a proper sense of honor, nor are ten years, nor fifteen, for during these long intervals there has been no attempt of the prevaricators to reconstruct their statements in conformity with the facts.

In conclusion, Dr. Cannon points out the fundamental wrong committed by the antivivisectionists, which is the presentation of accounts of medical research without any reference to its motives or its triumphs. They fail to express the important issues of disease and death which depend on the results of medical investigations, and they refuse to recognize that by the sacrifice of some animals the chances for life and health for mankind and for myriads of other animals as well, are enormously enlarged. The accounts of these inestimable blessings which have resulted from animal experimentation are now available to everyone in the pamphlets above referred to published by the American Medical Association.

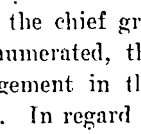
It is clear from the considerations given in this pamphlet that before the antivivisectionists can command the respectful attention of intelligent people they must fundamentally change their tactics. They must clear their literature of the superseded testimony of men long since dead, men who had no conception of the merciful procedures of modern experimentation, or of its life-giving results. They must rid their publications of the testimony of "experts" whose reputations, such as they are, were made in literature, art or theology, and not in medicine. They must purge their propaganda of the fraud and trickery and evil insinuation that have for years characterized it. And the process of making their methods clean and their ways straight should involve paying some respect to the high purpose of biologic investigation and its beneficent achievements for human welfare, which together give meaning and sanction to the experimental use of animals.

THE CHEMISTRY OF THE NUCLEINS

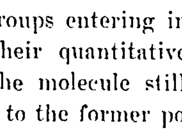
There is probably no field of science in which greater progress has been made recently than in organic chemistry, and not the least spectacular development of this has been along physiologic lines. Late years have witnessed a fairly adequate solution of the riddle of proteid composition, and in a recent article Kossel,[1] himself among the foremost investigators, summarizes the progress made toward the analysis of a similar problem—the composition of the nucleins. Nuclear materials from manifold sources all indicate these substances as the essential element in the composition of the nucleus; and when the importance of the latter is realized in all processes that are considered most peculiarly vital, the value of the study of the nucleins can be appreciated. In general it has been found that these can be split into two main constituents, a proteid and nucleic acid. The former does not differ radically from proteids from other sources; and it is the composition of the latter that forms the main problem of this particular phase of organic chemistry. By subjecting various nucleic acids to the less powerful means of chemical decomposition, it is possible to obtain certain groups which, by their junction, apparently build up the complex molecule. The nitrogen-containing groups so far found are four in number—thymin, cytosin, guanin, and adenin. The two former have a single, the two latter a double, carbon and nitrogen ring—this last being the so-called purin ring.



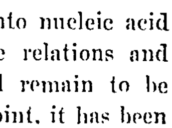
Thymin.



Cytosin.



Guanin.



Adenin.

The remaining part of nucleic acid can in turn be broken up into two main constituents—phosphoric acid and a carbohydrate.

Although the chief groups entering into nucleic acid are thus enumerated, their quantitative relations and their arrangement in the molecule still remain to be investigated. In regard to the former point, it has been found that for each of the four nitrogen-containing groups there are in the molecule one each of the carbohydrate and phosphoric acid groups, thus giving at the very least twelve of these simpler bodies for each nucleic acid molecule. Needless to say, the nucleic acids from various sources differ in composition, and there are countless ways in which this may occur. So nucleic acids have been found in which one or more of the four nitrogen-containing groups are absent. The carbohydrate in turn may have only five carbon atoms, instead of the usual six, or conceivably even less.

---

[1] München. med. Wchnschr., 1911, lviii, 65.

The proteid and nucleic acid, forming by their union a nuclein, may vary considerably in the way they are joined. In some cases the union is a feeble one, and in others it is so strong as to offer obstinate resistance to decomposition. One of the chief sources of material for the study of the nucleins has been the heads of spermatozoa of various animals, and it is a peculiar fact that the firm type of union has been found in the sperm nucleins of warm-blooded animals, while lower forms of life have the other type. Unfortunately, not enough work has as yet been done to justify generalization on this point. In those cases in which the proteid molecule has been found loosely held, the union is similar to that of a base and an acid to form a salt. Such proteids are much more strongly basic in character than usual, and the explanation has been found in their chemical composition. The groups forming a proteid molecule are for the most part of the "amido-acid" type—that is to say, they possess an acid as well as a basic, amido (NH_2) radicle. A simple instance of such an amido-acetic acid,  $H_2{=}\underset{\underset{H_2}{N}}{\overset{}{C}}{-}COOH$, in which the COOH group possesses acid, the NH_2 basic properties. In the more complex amido-acids there may be more than one amido group, and it is of this type that the basic proteids—those found loosely bound to the nucleic acid—are composed. Other more complex nitrogen groups, that also impart basic properties to the molecule, occur in them as well, giving these proteids a nitrogen percentage much higher than that of the more usual forms.

It will be seen that considerable progress has already been made toward the solution of the problem of nuclear composition. Since it is the chromogenic—the nuclein—portion of the nucleus that initiates cell division and, according to our present belief, transmits the hereditary functions of all life, the further developments of this subject assume an importance far beyond the scope of the chemical problems involved.

VAN 'T HOFF AND MEDICAL SCIENCE

There are certain persons who are fond of insisting that the fundamental medical sciences should be taught in what they are pleased to call a "practical" manner. They resent the growing tendency to insist that the preliminary education in science subjects should be given in colleges and universities rather than in the medical schools. "Medical chemistry and medical physics," they say, "should be taught by medical men in medical schools, so that the students may learn what is of practical use to physicians without wasting their time on matters of mere theory."

If a refutation of these arguments were necessary there could be found no illustration better than that furnished by the entrance of physical chemistry into medical science. How many men who were taught chemistry in the average American medical school by the "practical teacher" two decades ago, or even half as long ago, were given the slightest inkling of the then theoretical subject of physical chemistry? We doubt that there were any — certainly they were few, and fortunate in that their teachers were less "practical" than they were supposed to be. Yet at this time the same graduates, now in their best years, know that progress is being made behind what to them must remain a closed door, unless they have the time and the rare energy to go back and make up one of the many defects in their training, for which not they themselves but a faulty system of education is responsible. None of us can foretell what direction progress will take, and we know not which scrap of theory of to-day will be the foundation of our great advances a few years hence. The plant cells and salt solutions of de Vries and the semipermeable membranes of Traube, unknown to the medical teacher two decades ago, were then pointing out lines of investigation whose fruits are now being reaped by physiology and pathology, and prepared for the clinical medicine of the near future. Therefore we must teach our fundamental sciences as sciences, and provide our students with a grasp of principles which will enable them to understand the new developments in these sciences, rather than equip them with a catalogue of supposedly useful information which may be useless slag by the time their diplomas are framed.

We are impelled to the foregoing reflections by the news of the death of Prof. J. H. van 't Hoff, the eminent Dutch chemist, since 1895 professor of general chemistry in the University of Berlin, and in 1901 awarded the Nobel prize for physicians. His was one of the great minds in which were developed the fundamental ideas which have brought physical chemistry into the foreground during the past quarter of a century, and for the assistance afforded to physiology and pathology over many hard places in their road by this new arm of chemistry must medicine be grateful.

The botanists Pfeffer and de Vries developed many of the fundamental facts on which depends the theory of osmotic pressure, advanced by van 't Hoff in 1885, and on which his fame most largely rests. This theory, amplified, and corrected as to certain features by the discovery of Arrhenius of the principles of electrolytic dissociation, has been of the utmost service in all the biologic sciences. It is, indeed, impossible to consider any vital phenomena without taking into account the osmotic pressure of the solutions in which they occur, and the influence of the diffusion membranes which form the cell walls and the nuclear boundaries. To understand hemolysis, phagocytosis, absorption, secretion, edema, expansion and contraction of cells, the action of drugs and poisons, without a real knowledge of the principles of solution and osmotic pressure, is entirely out of the question, and the terminology of physical chemistry is as familiar to the well-trained medical student to-day as was Gray's "Anatomy" to the student of an earlier generation. It is perfectly safe to say that physical chemistry will give fully as much to medicine as organic chemistry; and it is our duty to realize that it is to such masters as van 't Hoff, who furnish us with principles, that we are indebted, more than to those who merely apply them to our immediate needs and uses.

ADVERTISING—LAY AND MEDICAL

The fight during the last five or ten years for decency and truthfulness in advertising has had one result: many newspapers and magazines no longer accept advertising "copy" in which untruthfulness and fraud are evident. As a corollary of this state of affairs, many advertisers no longer prevaricate in the advertising pages of the journals they patronize; they confine their untruthfulness to the circular letters and advertising leaflets which they send out direct. For this reason it has become increasingly difficult to convince publishers that many a firm whose advertising they accept is perpetrating a fraud on the readers of their magazines and newspapers.

This point was recently emphasized in a letter from the editor of a popular health magazine—*Life and Health*—calling attention to the degree of watchfulness that a publisher must exercise, if he desires to keep his advertising pages clean. The editor in question sent us a booklet issued by a firm that advertised in his magazine—the Robinson Manufacturing Co. of Toledo, Ohio. This concern manufactures and sells portable Turkish-bath cabinets—devices, one would imagine, that could be sold on their merits. The advertisements, as they appeared in different magazines, were practically unobjectionable; the booklet, however, sent direct from the company to the prospective customer, contained the most preposterously false and fraudulent claims. For example:

> "Kills the poisons of nearly every disease known to physicians."
>
> "Quickly destroys the uric acid of rheumatism and malaria."
>
> "Destroys the germs of consumption or tuberculosis by the heat produced."

These are but some of the claims made for the Robinson bath cabinets. The editor of *Life and Health* says that as soon as he saw the booklet, he at once rejected the firm's advertising on the grounds that he does "not believe it is consistent with our policy of teaching right principles to advertise such literature."

The effect this action had on the advertising agent of the magazine was thus described by the editor:

> "I have constantly refused to accept this class of advertising, and it has rather 'queered' our advertising agent, who thinks I have taken an extreme view of things, and it certainly has been a policy that has very greatly diminished our advertising receipts. It is not a policy that helps our subscription list very much."

We have here, briefly, the problem that confronts the publisher of every journal, lay or medical, when he uses discrimination in the acceptance of advertisements. It is not surprising that the advertising agent thinks the publisher of a lay journal is "extreme" when he refuses to accept any advertisement that finds acceptance in supposedly reputable medical journals. Yet, we find a well-known New York medical weekly as well as other medical journals carrying advertisements of this bath cabinet and reputable physicians lending moral and financial aid to these journals both by subscribing for and by contributing to them. No wonder newspapers and magazines accept advertisements of things of a medical nature that are fraudulently exploited, so long as medical journals will accept similar advertisements! Nor is it surprising that the physician who writes to a lay publication, protesting against the medical advertisements therein, receives a letter suggesting that, before the medical profession tries to reform the lay press, it should first clean its own skirts.

Current Comment

A DEMONSTRATION OF ARMY SANITATION

The mobilization of a large force of men on the Mexican border by the military authorities will give opportunity for a demonstration of such improvement in army sanitation and hygiene as has been made since the Spanish-American War in 1898. The lesson of that war was severe. On account of lack of an adequate medical staff, organization, equipment and appropriations—a grievous unpreparedness for actual field conditions—the mortality and morbidity of the forces, under simple camp conditions, which, on account of the absence of danger of invasion by the enemy, should have been under complete control, were not much better than those of the Civil War. The possibilities of camp and army sanitation under actual war conditions were well demonstrated by the Japanese in their war with Russia. It remains to be seen whether our army has profited by these two examples. Improvement has undoubtedly been made, and conditions, in the regular army at least, under practice-camp conditions, with comparatively small forces, have perhaps become almost ideal. The experience with small forces in the Philippines has also no doubt served a useful purpose in teaching the requirements of army sanitation under war conditions. Even though the mobilization of the present forces is only intended for maneuver purposes, the conditions will more nearly simulate actual war conditions than any movements of the army during the last decade. In a semi-tropical country, with scant or defective water-supply, with possibilities of malaria and other infectious diseases, the resources and organization of the medical department would be practically tested.

nitrogen-containing groups are absent. The carbohydrate in turn may have only five carbon atoms, instead of the usual six, or conceivably even less.

The proteid and nucleic acid, forming by their union a nuclein, may vary considerably in the way they are joined. In some cases the union is a feeble one, and in others it is so strong as to offer obstinate resistance to decomposition. One of the chief sources of material for the study of the nucleins has been the heads of spermatozoa of various animals, and it is a peculiar fact that the firm type of union has been found in the sperm nucleins of warm-blooded animals, while lower forms of life have the other type. Unfortunately, not enough work has as yet been done to justify generalization on this point. In those cases in which the proteid molecule has been found loosely held, the union is similar to that of a base and an acid to form a salt. Such proteids are much more strongly basic in character than usual, and the explanation has been found in their chemical composition. The groups forming a proteid molecule are for the most part of the "amido-acid" type—that is to say, they possess an acid as well as a basic, amido (NH_2) radicle. A simple instance of such an amido-acid is amido-acetic acid,  $H_2{=}\underset{\substack{|\\ N\\ H_2}}{C}{-}COOH$, in which the COOH group possesses acid, the NH_2 basic properties. In the more complex amido-acids there may be more than one amido group, and it is of this type that the basic proteids—those found loosely bound to the nucleic acid—are composed. Other more complex nitrogen groups, that also impart basic properties to the molecule, occur in them as well, giving these proteids a nitrogen percentage much higher than that of the more usual forms.

It will be seen that considerable progress has already been made toward the solution of the problem of nuclear composition. Since it is the chromogenic—the nuclein—portion of the nucleus that initiates cell division and, according to our present belief, transmits the hereditary functions of all life, the further developments of this subject assume an importance far beyond the scope of the chemical problems involved.

VAN 'T HOFF AND MEDICAL SCIENCE

There are certain persons who are fond of insisting that the fundamental medical sciences should be taught in what they are pleased to call a "practical" manner. They resent the growing tendency to insist that the preliminary education in science subjects should be given in colleges and universities rather than in the medical schools. "Medical chemistry and medical physics," they say, "should be taught by medical men in medical schools, so that the students may learn what is of practical use to physicians without wasting their time on matters of mere theory."

If a refutation of these arguments were necessary there could be found no illustration better than that furnished by the entrance of physical chemistry into medical science. How many men who were taught chemistry in the average American medical school by the "practical teacher" two decades ago, or even half as long ago, were given the slightest inkling of the then theoretical subject of physical chemistry? We doubt that there were any—certainly they were few, and fortunate in that their teachers were less "practical" than they were supposed to be. Yet at this time the same graduates, now in their best years, know that progress is being made behind what to them must remain a closed door, unless they have the time and the rare energy to go back and make up one of the many defects in their training, for which not they themselves but a faulty system of education is responsible. None of us can foretell what direction progress will take, and we know not which scrap of theory of to-day will be the foundation of our great advances a few years hence. The plant cells and salt solutions of de Vries and the semipermeable membranes of Traube, unknown to the medical teacher two decades ago, were then pointing out lines of investigation whose fruits are now being reaped by physiology and pathology, and prepared for the clinical medicine of the near future. Therefore we must teach our fundamental sciences as sciences, and provide our students with a grasp of principles which will enable them to understand the new developments in these sciences, rather than equip them with a catalogue of supposedly useful information which may be useless slag by the time their diplomas are framed.

We are impelled to the foregoing reflections by the news of the death of Prof. J. H. van 't Hoff, the eminent Dutch chemist, since 1895 professor of general chemistry in the University of Berlin, and in 1901 awarded the Nobel prize for physicians. His was one of the great minds in which were developed the fundamental ideas which have brought physical chemistry into the foreground during the past quarter of a century, and for the assistance afforded to physiology and pathology over many hard places in their road by this new arm of chemistry must medicine be grateful.

The botanists Pfeffer and de Vries developed many of the fundamental facts on which depends the theory of osmotic pressure, advanced by van 't Hoff in 1885, and on which his fame most largely rests. This theory, amplified, and corrected as to certain features by the discovery of Arrhenius of the principles of electrolytic dissociation, has been of the utmost service in all the biologic sciences. It is, indeed, impossible to consider any vital phenomena without taking into account the osmotic pressure of the solutions in which they occur, and the influence of the diffusion-membranes which form the cell walls and the nuclear boundaries. To understand hemolysis, phagocytosis, absorption, secretion, edema, expansion and contraction of cells, the action of drugs and poisons, without a real knowledge of the principles of solution and osmotic pressure, is entirely out of the question, and the terminology of physical chemistry is as familiar to the well-trained medical student to-day as was Gray's "Anatomy" to the student of an earlier generation. It is perfectly safe to say that physical chemistry will give fully as much to medicine as organic chemistry; and it is our duty to realize that it is to such masters as van 't Hoff, who furnish us with principles, that we are indebted, more than to those who merely apply them to our immediate needs and uses.

ADVERTISING—LAY AND MEDICAL

The fight during the last five or ten years for decency and truthfulness in advertising has had one result: many newspapers and magazines no longer accept advertising "copy" in which untruthfulness and fraud are evident. As a corollary of this state of affairs, many advertisers no longer prevaricate in the advertising pages of the journals they patronize; they confine their untruthfulness to the circular letters and advertising leaflets which they send out direct. For this reason it has become increasingly difficult to convince publishers that many a firm whose advertising they accept is perpetrating a fraud on the readers of their magazines and newspapers.

This point was recently emphasized in a letter from the editor of a popular health magazine—*Life and Health*—calling attention to the degree of watchfulness that a publisher must exercise, if he desires to keep his advertising pages clean. The editor in question sent us a booklet issued by a firm that advertised in his magazine—the Robinson Manufacturing Co. of Toledo, Ohio. This concern manufactures and sells portable Turkish-bath cabinets—devices, one would imagine, that could be sold on their merits. The advertisements, as they appeared in different magazines, were practically unobjectionable; the booklet, however, sent direct from the company to the prospective customer, contained the most preposterously false and fraudulent claims. For example:

> "Kills the poisons of nearly every disease known to physicians."
>
> "Quickly destroys the uric acid of rheumatism and malaria."
>
> "Destroys the germs of consumption or tuberculosis by the heat produced."

These are but some of the claims made for the Robinson bath cabinets. The editor of *Life and Health* says that as soon as he saw the booklet, he at once rejected the firm's advertising on the grounds that he does "not believe it is consistent with our policy of teaching right principles to advertise such literature."

The effect this action had on the advertising agent of the magazine was thus described by the editor:

> "I have constantly refused to accept this class of advertising, and it has rather 'queered' our advertising agent, who thinks I have taken an extreme view of things, and it certainly has been a policy that has very greatly diminished our advertising receipts. It is not a policy that helps our subscription list very much."

We have here, briefly, the problem that confronts the publisher of every journal, lay or medical, when he uses discrimination in the acceptance of advertisements. It is not surprising that the advertising agent thinks the publisher of a lay journal is "extreme" when he refuses to accept any advertisement that finds acceptance in supposedly reputable medical journals. Yet, we find a well-known New York medical weekly as well as other medical journals carrying advertisements of this bath cabinet and reputable physicians lending moral and financial aid to these journals both by subscribing for and by contributing to them. No wonder newspapers and magazines accept advertisements of things of a medical nature that are fraudulently exploited, so long as medical journals will accept similar advertisements! Nor is it surprising that the physician who writes to a lay publication, protesting against the medical advertisements therein, receives a letter suggesting that, before the medical profession tries to reform the lay press, it should first clean its own skirts.

Current Comment

A DEMONSTRATION OF ARMY SANITATION

The mobilization of a large force of men on the Mexican border by the military authorities will give opportunity for a demonstration of such improvement in army sanitation and hygiene as has been made since the Spanish-American War in 1898. The lesson of that war was severe. On account of lack of an adequate medical staff, organization, equipment and appropriations—a grievous unpreparedness for actual field conditions—the mortality and morbidity of the forces, under simple camp conditions, which, on account of the absence of danger of invasion by the enemy, should have been under complete control, were not much better than those of the Civil War. The possibilities of camp and army sanitation under actual war conditions were well demonstrated by the Japanese in their war with Russia. It remains to be seen whether our army has profited by these two examples. Improvement has undoubtedly been made, and conditions, in the regular army at least, under practice-camp conditions, with comparatively small forces, have perhaps become almost ideal. The experience with small forces in the Philippines has also no doubt served a useful purpose in teaching the requirements of army sanitation under war conditions. Even though the mobilization of the present forces is only intended for maneuver purposes, the conditions will more nearly simulate actual war conditions than any movements of the army during the last decade. In a semi-tropical country, with scant or defective water-supply, with possibilities of malaria and other infectious diseases, the resources and organization of the medical department would be practically tested.

COMPRESSED OXYGEN

The report of the Council on Pharmacy and Chemistry in another part[1] of this issue shows how the work of this body is broadening. In the past the Council's reports have dealt with proprietary articles or with nonproprietary drugs which form the basis of proprietary medicines. The present report relates to an entirely different substance—oxygen—which, so far, is one of the few things which have not been appropriated by proprietary medicine houses. The purity of oxygen is a most important matter—more important than the purity of many official drugs—because it is often depended on to save a life that is at its lowest ebb, and where the slightest impurity might have the most serious consequences. While to those unfamiliar with analytical work of this nature, the amount of labor represented by the report of Professors Smith and Leman will not be apparent, it was none the less real. It is gratifying to find men of high standing outside of the profession ready to cooperate with the Council in its efforts to bring about better conditions. The good quality of the oxygen on the American market is a matter for congratulation.

PHYSICIANS AND DREADNAUGHTS

Spectacular heroism usually has a prompt reward in homage and praise; but that is a truer heroism which is unostentatious or unrecognized, because it is not for glory; rather it is an unselfish self-sacrifice. "Those missionary doctors who are going among the stricken natives in an effort to stamp out the plague are as great heroes as any who ever faced the yellow fever in their own country, and more so, because the duty did not come to them. They sought it out." Thus speaks the St. Louis *Star* of the situation in China, and adds this pointed comparison: "The missionary doctor presents a less spectacular picture to the eye than a dreadnaught, but he is a far better messenger for civilization to send to those who dwell in darkness." The spread of the bubonic plague in the East has inspired terror in the inhabitants and foreign visitors and many of the latter have made a hasty departure from the stricken regions. The physicians,[2] as always, are going about combating the pestilence in the most vigorous fashion, uninfluenced by fear or terror; and to compare them with dreadnaughts is indeed appropriate.

FAKES AND THEIR IMITATORS

The success, through advertising, of a nostrum which has little or no special merit, causes a host of imitators to spring up, in the hope of reaping a like profit in humbugging the people. But failure often results, because these imitators do not possess the business shrewdness or the means for advertising which were at the disposal of the original fake. This is emphasized in the March number of the *California State Journal of Medicine* which describes the Viavi fake. Its imitators are clumsy, but "they may be also deadly, as when they imply that cancer may be prevented or cured by the use of their stuff. They all forget that what has made the monumental success of the Viavi fake is not the fake itself—it is the keen, shrewd, cunning brain of the little Law brother, one of San Francisco's most wealthy and distinguished citizens. It is not the three little shells and the elusive little pea that are so valuable to the 'shell game' faker; it is the dextrous way in which he works the fake. The promoters of these clumsy imitators of the Viavi fake will never get to be directors of the Young Men's Christian Association; they have not the guiding genius of the little Law brother to manipulate the fake."

FIRST AID TO INJURED CREDIT

The general advantage to the public of instruction in "first aid to the injured" seems not to have been wholly realized heretofore. In a recent instance, after purchasing some goods in a store, a man offered in payment a check signed by a physician and asserted that he was the physician. The clerk, whose suspicions were aroused, asked the customer to state how many bones there are in the human body. The alleged physician was unable to do so, became confused, was arrested and proved to be an impostor. We hope that the employer appreciates the value of such a clerk. He has learned the first principle underlying first aid to the injured—that prevention is better than cure.

Medical News

ALABAMA

Society Meetings.—Hale County Medical Society, at its annual meeting in Greensboro, elected the following officers: president, Dr. Reuben F. Monette; vice-president, Dr. R. A. White, Jr.; censor, Dr. Edgar P. McCollum, and secretary-treasurer and county health officer, Dr. Charles A. Poellnitz, all of Greensboro; health officer, Dr. Shelby C. Carson for Greensboro; Dr. Elisha N. Driver for Newbern, and Dr. Rufus J. Griffin for Moundsville.——Dallas County Medical Society, at its annual meeting, held in Selma, elected the following officers: Dr. William W. Harper, Selma, president: Dr. Lawrence H. Moore, Orrville, vice-president; Dr. James S. Chisholm, Selma, secretary, and Dr. Samuel B. Allison, Carlowville, county health officer.

CALIFORNIA

Milk Commissions to Meet.—The third annual meeting of the California Association of Medical Milk Commissions will be held at Santa Barbara during the meeting of the State Medical Society which convenes April 18. The chief subject to be discussed at the meeting will be "Bovine Tuberculosis in Relation to Public Health." Papers on this subject will be read by Dr. George S. Baker, inspector in charge of the Bureau of Animal Industry, United States Department of Agriculture: Dr. C. M. Haring, professor of veterinary science in the University of California: Dr. M. E. Jaffa, professor of agricultural chemistry in the University of California, and Dr. Chester Roadhouse, formerly United States Meat Inspector, and expert to the San Francisco County Medical Milk Commission. Physicians, sanitarians and producers and consumers of milk are invited to attend the meeting.

ILLINOIS

Supreme Court Decision.—By a recent ruling of the supreme court in the case of *The People vs. Wilson, paragraph* 12 of the Medicine and Surgery Act is declared unconstitutional. This section has to do with the licensing of itinerant vendors of patent and proprietary medicines, which makes it necessary for such persons to pay a license of $100 a month for the privilege of selling medicines.

---

[1] N. N. R., page 813; Propaganda for Reform, page 833

[2] In this connection it will be of interest to note a letter from a missionary physician in China which appears in our Correspondence Department in this issue.

Personal.—Dr. Frederick A. Renner has been appointed local surgeon of the Illinois Traction System Hospital Association and of the Illinois Traction System at Benld.——Dr. Charles G. Beard, Sterling, has been appointed local surgeon for the Burlington System at Sterling and Rock Falls.——Dr. N. E. Wayman, Chicago, has been appointed state bacteriologist, vice Dr. William H. Holmes, resigned.

Chicago

Dismissal Confirmed.—Twelve members of the Board of Managers of Mary Thompson Hospital met, March 4, and confirmed the dismissal of seven members of the staff and two interns, who are said to have threatened to disrupt the hospital if they were not reinstated.

Get Together Banquet.—At the get together banquet, held March 9, by the Chicago Retail Druggists' Association, members of the Chicago Medical Society and the Chicago Odontographic Society were entertained. Dr. Alexander Hugh Ferguson presided as toastmaster. Harmony was the dominant note of the meeting.

Death-Rate Increasing.—In the quadrennial report of the department of health, the annual mortality for the period is given as 15.72 per 1, 000 in 1907, 14.49 in 1908, 14.58 in 1909 and 15.21 in 1910, showing an increase in the mortality rate for last year. This increase is in the deaths by violence, heart disease, cancer and nephritis. In the preamble of the report the health commissioner lays the responsibility of the increasing death-rate to lack of appropriations properly to carry on the work of the health department, which he says is handicapped by lack of men and money.

MARYLAND

Inmates Build New Asylum.—In the erection of the new State Insane Hospital for Negroes at Crownsville, near Annapolis, much of the labor is being done by negro inmates of the different asylums of the state.

Baltimore

New Hospital.—The South Baltimore General Hospital was chartered in January last. Among those connected with the institution are the mayor, and Drs. Guy L. Hunner, Harry E. Peterman and Anna S. Abercrombie. The incorporators are endeavoring to raise $100,000 for the buildings of the new hospital. A site will probably be chosen on the water front at Locust Point in the Fort McHenry district.

Diphtheria at Johns Hopkins.—The outbreak of diphtheria in Johns Hopkins Hospital is practically over. The health department publishes figures to show that the outbreak was confined to the hospital and to the Church Home and Infirmary, and that there has been no increase in the prevalence of the disease in the city at large. None of the cases in the hospital was serious as antitoxin controlled the disease satisfactorily. On March 11 there were still eight cases in the hospital, all in the isolation ward. Work at the Johns Hopkins Medical School was resumed March 8 and 9. The dispensary was opened March 9, and the dispensary at the Hebrew Hospital on the same date. The Church Home has been reopened for patients.

MASSACHUSETTS

Bequest to Hospital.—By the will of Mrs. Rosa A. Cole, Kingston, a bequest of $100,000 is made to the Jordan Hospital, Plymouth, and in addition the hospital is made residuary legatee of the estate.

Personal.—Dr. John W. Chase, Dedham, was struck by an automobile, March 5, fracturing two ribs and causing injuries to his knees and internal injuries.——Dr. William H. Ruddick, South Boston, has been appointed chief marshal of the Evacuation Day parade.

Benefactions to Hospitals.—By the will of the late Mrs. Williern O. Moseley, Newburyport, the sum of $200,000 is devised to Anna Jaques Hospital, Newburyport, and $60,000 to Harvard University for two fellowships to enable medical students of marked ability to pursue studies abroad.——The late Sullivan Niles, Cambridge, bequeathed $3,000 to the Cambridge Hospital.——Salem Hospital was bequeathed $5,000 by the late Edward Lane, Salem, for the establishment of a free bed.

MICHIGAN

Medical School Anniversary.—On February 22, the College of Medicine and Surgery of the University of Michigan, Ann Arbor, celebrated the anniversary of its foundation. Dr. Alfred S. Warthin addressed the evening meeting on "Disease in Art."

Object to Newspaper Exploitation.—The Hillsdale County Medical Society, at its meeting, March 3, adopted resolutions requesting the newspapers of the county to refrain from noting the names of physicians in connection with operations or cases of illness, on account of the publication being unethical and in the nature of advertising.

Reference Library for Kalamazoo.—It was announced at the February meeting of the Kalamazoo Academy of Medicine that a medical reference library will soon be installed in that city and made available for members of the profession. *The Bulletin*, a semi-monthly publication of the Kalamazoo Academy of Medicine, made its first appearance, February 25. It is an eight-page sheet, and contains the program for the succeeding session of the academy, and also other news items and reports of special cases.

Personal.—By the will of Miss Sarah Finney, $100,000 is devised to Dr. Andrew W. Imrie, Detroit.——Dr. A. Marion Allen, Adrian, was thrown from his buggy, February 26, breaking his clavicle.——Dr. Charles L. Grube, Saginaw, has compromised his claim against the city of Saginaw for services during the small-pox epidemic to $2,434.95.——Dr. Charles F. Kuhn, Detroit, was severely shaken up and bruised in a collision between his automobile and another car, February 13.——Dr. Joseph Foster, Lansing, who has been ill with influenza, is reported to be convalescent.——Dr. Henry F. Thomas, Allegan, was seriously injured in a runaway accident, March 4.——Dr. Jean H. Whitney-Morse, Battle Creek, sailed for Porto Rico, March 11.——Dr. J. Earl McIntyre has been appointed local surgeon of the Grand Trunk System at Lansing, vice Dr. George E. Ranney, promoted to district surgeon.

MISSOURI

Physicians Indicted.—Eleven indictments are said to have been returned by the United States grand jury at Kansas City against physicians of that city charged with violation of the federal statute which makes it a crime for any one to use the mails for the dissemination of information regarding the induction of abortion. The accused were arraigned February 28, pleaded not guilty and were released on bonds of $5,000 each.

Medical License Law Valid.—In the case of George F. Smith, Webster County, a chiropractic charged with "treating and attempting to treat the sick and afflicted without first having obtained a license from the State Board of Health," in which the defendant appealed to the supreme court, a decision has been handed down which sets forth "that the method of practice disclosed by this record may be harmless and useful, but this treatment for sick related, to say the least, to the practice of medicine or surgery and so within the terms of the statute."

St. Louis

Personal.—Dr. C. W. Gould, assistant city bacteriologist, who has been ill at the City Hospital, is reported to be improving.——Dr. Frederick B. Hall has been appointed roentgenologist at the City Hospital, vice Dr. Russel D. Carman, resigned.

Section Officers Elected.—The Section on Internal Medicine of the St. Louis Medical Society has elected Dr. Louis H. Behrens, chairman; Dr. Oliver H. Campbell, vice-chairman and editor, and Dr. Llewellyn Sale, secretary-treasurer.——The surgical section of the society has elected Dr. M. George Gorin, chairman; Dr. Roland Hill, secretary, and Dr. Edmund A. Babler, treasurer.

NEW YORK

Physicians in State Legislature.—The assembly numbers among its members four physicians: Drs. Minor McDaniels, health officer of Enfield Center; Charles S. Butler, health officer of Harpersville; Robert P. Bush, Horseheads, and John Seeley, Woodhull.

College Seeks New Site.—It is reported that Albany Medical College is endeavoring to secure from the board of supervisors of Albany County an easement transferring to the college the property formerly occupied by the Albany penitentiary as a site on which to erect new college and laboratory buildings.

Rochester Academy Meeting.—Owing to sudden illness, Dr. Frederick G. Novy, Ann Arbor, Mich., was unable to be present

Earl McIntyre has been appointed local surgeon of the Grand Trunk System at Lansing, vice Dr. George E. Ranney, promoted to district surgeon.

MISSOURI

Physicians Indicted.—Eleven indictments are said to have been returned by the United States grand jury at Kansas City against physicians of that city charged with violation of the federal statute which makes it a crime for any one to use the mails for the dissemination of information regarding the induction of abortion. The accused were arraigned February 28, pleaded not guilty and were released on bonds of $5,000 each.

Medical License Law Valid.—In the case of George F. Smith, Webster County, a chiropractic charged with "treating and attempting to treat the sick and afflicted without first having obtained a license from the State Board of Health," in which the defendant appealed to the supreme court, a decision has been handed down which sets forth "that the method of practice disclosed by this record may be harmless and useful, but this treatment for sick related, to say the least, to the practice of medicine or surgery and so within the terms of the statute."

St. Louis

Personal.—Dr. C. W. Gould, assistant city bacteriologist, who has been ill at the City Hospital, is reported to be improving.——Dr. Frederick B. Hall has been appointed roentgenologist at the City Hospital, vice Dr. Russel D. Carman, resigned.

Section Officers Elected.—The Section on Internal Medicine of the St. Louis Medical Society has elected Dr. Louis H. Behrens, chairman; Dr. Oliver H. Campbell, vice-chairman and editor, and Dr. Llewellyn Sale, secretary-treasurer.——The surgical section of the society has elected Dr. M. George Gorin, chairman; Dr. Roland Hill, secretary, and Dr. Edmund A. Babler, treasurer.

NEW YORK

Physicians in State Legislature.—The assembly numbers among its members four physicians: Drs. Minor McDaniels, health officer of Enfield Center; Charles S. Butler, health officer of Harpersville; Robert P. Bush, Horseheads, and John Seeley, Woodhull.

College Seeks New Site.—It is reported that Albany Medical College is endeavoring to secure from the board of supervisors of Albany County an easement transferring to the college the property formerly occupied by the Albany penitentiary as a site on which to erect new college and laboratory buildings.

Rochester Academy Meeting.—Owing to sudden illness, Dr. Frederick G. Novy, Ann Arbor, Mich., was unable to be present at the meeting of the Rochester Academy of Science, March 1, and the dinner in his honor was cancelled. Dr. Luzerne Coville, Ithaca, presented a paper before the academy on "Arteriosclerosis."

Hospital Notes.—Physicians of Babylon desire the establishment of a hospital in that village. The nearest hospital at present is that at Hempstead. The Board of Trade of Babylon has adopted a resolution favoring the project.——Auburn City Medical Society has adopted a resolution favoring the conversion of the present municipal hospital into a sanatorium for the care and treatment of tuberculosis patients.——Herkimer Emergency Hospital was obliged to close its doors, March 1, on account of financial stress. It is hoped that the hospital can be reorganized on a satisfactory basis.

New York City

Donation to Hospital.—Mr. Adolphus Busch, on the occasion of his golden wedding, March 7, donated $5,000 to the Children's Hospital.

Last Harvey Society Lecture.—The last lecture in the Harvey Society course will be delivered at the New York Academy of Medicine, April 1, by Dr. S. Weir Mitchell, Philadelphia, and will be "A Lecture on William Harvey, the Discoverer of the Circulation of the Blood."

Hospital in Hotel.—A unique feature in a new hotel now in the course of construction at Thirty-Fourth Street and Broadway, will be a hospital so arranged as to accommodate twelve patients at one time. This hospital is to be situated on the twenty-third floor of the hotel.

Department of Health Bulletin.—The Department of Health of the City of New York has undertaken the publication of a monthly bulletin which is supplied free of cost. The bulletin is intended for the information of public health officials, physicians and laymen interested in health problems, and will contain in each issue editorials and special articles dealing with various phases of public health work. The bulletin will appear about the fifteenth of each month.

Bellevue Overcrowded.—In this institution, whose normal capacity is 1,050, the average census for February was 1,200. On March 2 the number of patients was 1,330, the highest in the history of the institution. The authorities complain that they have been unable to transfer patients to the Metropolitan or the City Hospital for several weeks as these institutions are also overcrowded. The charter of Bellevue provides that whenever a case ceases to be a proper one for treatment at Bellevue, it shall be transferred to the Metropolitan or City Hospital on Blackwell's Island and a meeting of the trustees has been called to request the city to make some provision for patients from Bellevue.

Reorganization of Hospital.—At the reorganization of St. Mark's Hospital, March 7, the following new board of directors was elected: president, Dr. Benjamin T. Tilton; vice-president, Dr. Alexander Shulman; secretary, Dr. Andrew Von Grimm, and Drs. Otto Maier, Caesar A. Von Ramdohr and Charles R. L. Putnam. The following were added to the medical board: Drs. Benjamin T. Tilton and Charles R. L. Putnam, visiting surgeons; Dr. Andrew Von Grimm, visiting gynecologist; Dr. Otto Maier, visiting pediatrician and obstetrician; and Dr. Harry G. Watson, attending physician and visiting gastro-enterologist to St. Mark's Hospital Dispensary. Dr. Carl Beck resigned as visiting surgeon.

Medical Conferences.—Conferences have been arranged by the Educational Alliance with the endorsement of the Comitia Minora of the Medical Society of the County of New York and of the Council of the New York Academy of Medicine. They are given in the Auditorium, 197 East Broadway, corner Jefferson Street, at 8:30 p. m. On March 30, Dr. Henry C. Coe will speak on "Gynecological Operations by the General Practitioner." On April 9, Dr. Albert A. Berg will speak on "Lodge and Contract Practice." On April 17, Dr. Wm. M. Polk will speak on "Medical Ethics and Their Application to Practice." On April 23, Dr. Joseph Brettauer will speak on "The Secret Division of Fees." On April 27, Dr. Sigismund S. Goldwater will speak on "Abuses of Hospital and Dispensary Practice." These lectures are for physicians only.

NORTH CAROLINA

District Society Meeting.—The Fourth Councilor District Medical Society held its annual meeting in Wilson, February 14. The following officers were elected: president, Dr. James J. Philips, Tarboro; vice-presidents, Drs. William Spicer, Goldsboro, and Lacy D. Wharton, Smithfield, and secretary-treasurer, Dr. Michael M. Saliba, Wilson (reelected). The next meeting of the society will be held in Smithfield.

McCormack in North Carolina.—Dr. Joseph N. McCormack, Bowling Green, Ky., delivered an address before the North Carolina Association for the Prevention of Tuberculosis, and the members of the state legislature, Raleigh, February 1. At the conclusion of the address, State Senator Boyden, leader of the majority, rose, and in words of strong commendation told Dr. McCormack to have the physicians ask for what was needed to carry out the principles of public sanitation advocated by him, and the appropriation would be forthcoming. During the following week, Dr. McCormack in company with Dr. Chalmers M. Poole, Salisbury, president of the Medical Society of North Carolina, visited a number of the larger cities of the state and addressed large audiences.

Responsibility of Hotel Keepers.—The Supreme Court of North Carolina has recently handed down an opinion of possible interest to sanitarians, in the case of Patrick vs. Springs. Action was brought in the superior court several months ago against the keeper of a hotel in Washington, N. C., for damages suffered by the plaintiff by reason of having been assigned to an unsanitary room in which there was an unsafe or leaky gas fixture. The lower court awarded the plaintiff $250, and this award was sustained by the opinion of the supreme court, which was as follows: "It seems now to be well settled that in case of an injury occurring in consequence of the unsanitary and defective condition of the inn, premises or room to which a guest is assigned, the innkeeper is liable on the same principles applicable in other cases where persons come on the premises at the invitation of the owner or occupant and are injured in consequence of their dangerous condition."

OHIO

Personal.—Drs. Oscar Hasencamp, Toledo; Henry T. Sutton, Zanesville, and Robert H. Grube, Xenia, have been appointed members of the State Board of Health.——Dr. Thomas M. Sabin has been reelected president, and Dr. Frederick K. Smith, secretary of the staff of the Warren City Hospital.——Dr. Andrew J. Timberman, Columbus, is reported to be seriously ill with septicemia, due to an operation wound.

Tuberculosis Workers Incorporate.—The Columbus Society for the Prevention and Cure of Tuberculosis was incorporated March 4. The charter gives the society the right to acquire property, erect a hospital, employ nurses for patients, and teach methods of combating the disease. The prime object is to open the fresh-air school for which option on the Guerr Park property has been taken. Of the $5,500 required for this project, $3,600 has already been subscribed.

New National Guard Surgeons.—Dr. Edwin A. Hamilton, Columbus; John R. McDowell, Zanesville; James C. Pence, Lima; Don C. Hughes, Findlay, and Edward J. Wilkinson, Toledo, have passed the promotional examination and have been commissioned captains and assistant surgeons, M. C. O. N. G. Drs. Elijah J. Gordon, Columbus; Charles W. Stone, Cleveland, and Paul W. Tappan, Dayton, have passed the examination and have been commissioned first lieutenants and assistant surgeons in the medical corps.

Addition to Hospital.—Flower Hospital, Toledo, is about to award the contract for a new building which will more than quadruple the present capacity. The new building will contain ninety rooms and will cost about $100,000. The new staff of the hospital is made up as follows: chief of staff, Dr. Sidney D. Foster; surgical chief, Dr. Charles N. Smith; medical chief, Dr. Willard J. Stone; surgery, Drs. Sidney D. Foster, Albert F. McVety, Homer H. Heath and Clarence D. Selby; gynecology, Drs. Charles N. Smith, C. W. Worts and Joseph F. Fox; medicine, Drs. Willard J. Stone and Charles F. Tenney; pediatrics, Dr. George L. Chapman; eye, ear, nose and throat, Drs. Charles Lukens and Walter H. Snyder; obstetrics, Dr. William G. Dice; nerves, Dr. Louis Miller; dermatology, Dr. Edwin D. Tucker, and *x*-ray, Harry Dachtler.

Cleveland

Midwife Imprisoned.—Mrs. Annie Smith, a midwife of Cleveland, is said to have been committed to the workhouse for failure to report a case of ophthalmia neonatorum.

Personal.—Dr. Albert M. Dunlap, ward physician of the Eleventh Ward, is reported to be seriously ill with scarlet fever, contracted while attending a case in his district.——Dr. Hal F. Bishop, Cleveland, was committed to the Cleveland State Hospital for the Insane, March 6.——Dr. Charles M. Simpson has returned from abroad.

Hospital Notes.—Charity Hospital is endeavoring to raise $210,000, $150,000 of which will be used to erect a new surgical ward, and the remainder to liquidate a debt of the institution.——A site has been secured by Lakeside Hospital, on which a maternity and children's hospital will be erected. Work on these will be started this year.

PENNSYLVANIA

Electrocution Bill Passes House.—The Morris electrocution bill passed the house on final reading on March 9 and was presented to the senate on March 12. The bill provides for the substitution of the electric chair for the gallows in carrying out the death penalty.

Women Elect New Officers.—At the annual meeting of the Woman's Medical Association of Pittsburg, held February 28, Dr. Caroline S. Marshall was elected president; Dr. Bertha E. Dornbush, vice-president; Dr. Elizabeth Anderson, secretary, and Dr. Johanna Baltrusaitis, treasurer.

Charity Home Fund.—Mrs. Eckley B. Coxe, on March 1, contributed $2,000 to the fund being raised for a United Charities Home in West Hazleton. Her subscription was the first received. The organization is attempting to raise $15,000.

Site for Convicts' Hospital.—Robert J. McKenty, warden of the Eastern Penitentiary, Dr. Samuel Dixon, State Health Commissioner, and John Francis, warden of the Western Penitentiary, form a committee of three, provided for by a bill introduced into the senate by Mr. McNicholls of Lackawanna County, to visit Far View, Wayne County, to select a site for a hospital in which tuberculous convicts will be segregated.

Railway Fatalities.—Statistics gathered by the State Railway Commission show that during January, 87 persons were killed and 664 injured on the steam railroads of the state. Of the fatalities, 34 were employees, 2 passengers, 48 trespassers and 7 others. There were 8 deaths at grade crossings. During the same period, there were 13 killed on the street railways and 272 injured. Of the killed, 5 were trespassers and 8 others.

Conflict Between Health Department of State and City.—A conflict between the State Health Department and the Lancaster Board of Health has resulted in the arrest of Dr. J. Miller Shartle, Lancaster, state registrar. A local ordinance requires that physicians shall report deaths to the City Board of Health. Dr. Shartle holds that having reported to the State Health Department, he had fulfilled all legal obligations. As it is desirous to determine the authority of the state, in the premises, Dr. Shartle will be represented by counsel from the attorney general's department.

To Investigate Rittersville State Hospital.—An investigation of the construction of the Homeopathic State Hospital for the Insane at Rittersville, is provided for in a resolution presented to the senate, February 27, by Senator Judson. The resolution, which is referred to the judiciary special committee, recites that more than $1,700,000 of the State's money has been expended by the commission appointed to construct the institution; that the hospital is not yet completed, and has never housed or treated a patient, although the commission has been in existence since 1901. The resolution provides for the appointment of a committee which shall make a full investigation of the matter and hold public hearings.

Fireworks Manufacturers Favor Sane Fourth.—The Pennsylvania manufacturers of fireworks have volunteered to support the bill that has been presented to the legislature for the restriction of the sale and use of high explosives. The bill was formulated by the president of the Philomusian Club, who has been assured by virtually all the large dealers in fireworks in the state that, although the bill will certainly injure their trade, they feel it such a needed protection for children that the bill will not be contested, and its success therefore seems assured. The bill is aimed principally against the blank cartridge and provides that no blank cartridge, pellet or tablet, composed of chlorate of potash, dynamite or other high explosive compounds, shall be used in pistols, hollow canes or other toys for explosive purposes; that no fireworks containing gunpowder or like explosive material shall be over 6 inches in length and that no firecrackers containing gunpowder or like explosive materials shall be over 6 inches in length, and that firecrackers from 3½ to 6 inches long shall not be more than ¾ of an inch in diameter. The bill also aims to prevent manufacturers from importing the materials above mentioned from other places.

Philadelphia

Personal.—Dr. Harry Toulmin sailed for Europe, March 11. ——Dr. Helen Kirshbaum was operated on for appendicitis in the German Hospital, March 2

Trichinosis Prevalent.—It is reported that trichinosis is again prevalent in this city, causing at least one death during the past week. It is believed that the meat containing the trichinosis germ has been sold principally in the southeastern sections of the city as the majority of cases have been reported from that district.

The Midwife Abuse.—The weekly roster of the medical organizations of Philadelphia states that "a serious problem that soon must be solved by the Philadelphia profession is the present inadequate requirements for licensing of so-called midwives. This lawless element is a large factor in the growing crime of criminal abortion and must be controlled or perhaps suppressed. The Board of Health censured a local physician as recently as last week, for his carelessness in recommending certain women for licensure of this kind."

Cocain Users Sentenced.—A raid on a house at Thirteenth and Kenilworth Streets on March 8, resulted in the arraignment of seven alleged cocain users before Magistrate Barrett the next day. Mulvena Winter and Robert Sampson, colored, keepers of the house, were held in $500 bail each, for court, charged with obtaining and selling cocain among the colored people. Two men and two women, colored, were given three months each in the House of Correction. A white man also arrested at the house was given 6 months.

Dealers Oppose Milk Test.—On March 8, the "Downtown" Milk Dealers Association met in Ritter's Hall to protest against a bill introduced in the legislature by Representative McGuire, of Lackawanna County, providing for a 60 degree test in milk and for pasteurization of all milk. They declared that a 60 degree minimum temperature requirement would be an impossibility in the summer months, that the farmers oppose it and the railroads, by furnishing refrigerating cars, will raise rates, thereby forcing an increase in the retail price of milk.

Eulogium on Dr. Kelly.—At a special meeting of the faculty of the Woman's Medical College of Pennsylvania, March 3, a minute was adopted on the death of Dr. Aloysius Oliver Joseph Kelly, formerly professor of pathology in that institution, setting forth their appreciation of his rare mental qualities and his judicial character. He was from the first a leader in the cause of advanced medical education. He was a rare combination of amiability and strength, of a peace-maker and a combatant. He was most esteemed by those who knew him best.

Pure Food Work.—Gorgonzola cheese, imported into this city from Italy, has been found to bear a thick coating of paint said to contain barytes or barium sulphate with iron rust sprinkled on it for color. These cheeses were analyzed by Charles H. LaWall, Department Chemist.——On February 28, the federal agents confiscated 10,800 packages or 1,350 pounds of alleged impure gelatin at a wholesale grocery store on South Front Street.——On March 1, S. Sklaroff and Sons, smoked fish dealers, paid to Magistrate Beaton four fines amounting to $265, for selling smoked fish said to have been dyed.

Plans for Immigrant Hospital.—Plans for utilizing the upper deck of the new Vine Street Pier, or perhaps building a third deck to the pier to be equipped for a detention hospital for immigrants, was considered at a conference held February 27 and attended by Mayor Reyburn, Director Neff of the Department of Health and Acting Director Hasskarl, of the department of wharves, docks and ferries. A great many cases of contagious diseases, not extraditable under the quarantine laws, are brought into the city by immigrants exposing the public to risk. It is planned that all immigrants who show any symptoms of illness shall be detained at this new hospital for treatment and observation.

Pupils Begin Lunch Test.—At the request of the Home and School League, 50 children of the Woods School have been selected for experimental purposes, that is they are to be given warm luncheons at recess time, consisting of soup, stewed fruits, cocoa and bread for the period of a month. Since November, the League has been serving a three-cent lunch in two schools. As the children are unable to secure the luncheons daily, however, the league is determined to prove the value of the institution by providing the food free for fifty children and, by comparing their condition before and after the lapse of a month, obtain the needful argument in favor of the substantial lunch. These children have been subjected to a strength test, been weighed and careful notation of their physical condition made. The lunches will be varied each day and only the most nutritious food will be served.

Open-Air Schools to be Established.—Through the aid of the Phipps Institute, the first open air school for tuberculous children will be opened on the roof of the McCall School, April 1. March 8. Alexander Wilson, secretary of the social service department of the Phipps Institute, met the elementary school committee and offered in the name of the institute to provide the equipment and organize the class if the board would allow the use of the school roof and furnish a teacher. The roof will be furnished with needed protection at the expense of the institute and the children will be provided with extra clothing. It will be conducted on the lines of a hospital with given hours for recreation, light occupation and study. Cots will be provided where the children will be required to rest at stated intervals and milk and eggs will be fed to them. Another class of less advanced cases will be conducted in an open air room of the Jackson School at Twelfth and Federal Streets. Director Neff has notified the committee that the State Antituberculosis Association has in its possession about $2,000 as its share of the proceeds of the Fairmount Park automobile races which could be used for this purpose.——Residents of South Philadelphia have begun an agitation in favor of an open-air school for children of their section, who may be suffering from tuberculosis or threatened with the disease.

TENNESSEE

New Methodist Hospital—Plans are being formulated by the members of the Memphis, White River, North Mississippi and Mississippi conferences of the Methodist Episcopal Church, South, to erect a hospital in Memphis to cost $250,000.

Health Board Appointments.—At a meeting of the Nashville City Board of Health, Dr. William E. McCampbell was elected chairman, vice Dr. W. Frank Glenn. The board has reelected Dr. R. Logan Jones as city bacteriologist and chemist; Dr. John T. Altman has been reappointed a member of the board.

Closer Union of Medical Schools.—Two years ago the Medical Department of the University of Nashville was united with the Medical Department of the University of Tennessee, taking the name of the Medical Department of the Universities of Nashville and Tennessee. The union, however, was only for a limited number of years. Efforts are now being made, according to reports, to secure legislation making this union permanent.

TEXAS

Quarantine Fees for Hospital.—The Medical College of the University of Texas, at Galveston, is asking the legislature to grant the use of the quarantine fees at Galveston for the establishment and maintenance of a hospital in connection with the quarantine station at that point.

Yellow Fever in Mexico.—Reports of yellow fever in Mexico have caused the state health board alarm, and it is likely that a rigid quarantine will at once be established. On March 8, the state health officer, Dr. Ralph Steiner, went to Brownsville, on the Mexican border, to investigate the situation.

Health Bills.—The Texas Legislature is being asked to enact a law providing for the establishment of a state tuberculosis sanitarium; one to prohibit the use of public drinking cups; one to give the so-called "optometrists" a monopoly of the glass-fitting business, and one to perform on criminals and defectives the operation of vasectomy. Nearly all of these measures will die on the calendar.

Enacting a Sanitary Code.—The Texas legislature, now in session, will enact into law the sanitary code for Texas, which has had thus far only quasi-constitutional standing, in that the legislature at first sought to delegate to the state health board authority to enact the code. In Texas the legislature cannot delegate authority to make laws, so it has been difficult hitherto to make fines hold in the case of violators of the health laws. The bill has been unanimously passed by the senate and will undoubtedly receive similar treatment in the house, and the signature of the governor.

Distribution of Diphtheria Antitoxin.—State Health Officer Dr. Ralph Steiner, Austin, has just made arrangements whereby the state health board, is enabled to distribute diphtheria antitoxin at exceedingly low prices for the benefit of city and county health officers and other physicians who desire antitoxin for indigent patients. The state health officer will handle no funds, but will merely hold the antitoxin subject to the order of those who will be directly responsible to the manufacturing company. It is hoped that city and county administrators will take suitable official action for the free distribution of diphtheria antitoxin.

Hookworm Campaign.—Wickliffe Rose, secretary of the Rockefeller movement against the hookworm, has just conferred with the state health authorities, relative to the perfecting of a plan for the extermination of the parasite in Texas. Last fall Governor Campbell disapproved the plan to accept Rockefeller's aid, saying that Texas can better endure the hookworm than to lay itself debtor to Rockefeller. Governor Colquitt may entertain similar views. State Health Officer Dr. Ralph Steiner, however, will exert every energy to secure a portion of the Rockefeller fund. Recent investigations among the students of the medical branch, at Galveston, of the University of Texas, revealed the fact that 43 per cent. of the students are afflicted with uncinariasis.

WYOMING

Personal.—Dr. John B. Tyrrell, Laramie, has been appointed a member of the State Board of Medical Examiners, vice Dr. Samuel B. Miller, Laramie, resigned. Dr. Miller has moved to California.——Dr. W. W. Vance, recently appointed a member of the board of health of New Castle, at the organization of the board, was elected secretary.

FOREIGN NEWS

Northland Congress of Internal Medicine.—The seventh Scandinavian congress for internal medicine is to be held early in July, 1911, at Bergen.

International Congress of Pathology.—The date of this international gathering of pathologists has been fixed as Oct. 2-5, 1911; Turin is the place of meeting. The notices are being sent out by Prof. P. Foa, Corso Raffaello 30, Turin, in the name of the Societa Italiana di Patologia.

International Congress of Surgery.—The third congress of the International Surgical Association is to be held at Brussels Sept. 26-30, 1911, with an exhibition of fractures and methods of treatment in addition to the usual exhibition of surgical instruments and appliances. The three subjects to be discussed are surgery of the lungs and pleura, colitis and pancreatitis. Prof. Depage is the secretary general, Avenue Louise 75, Brussels, Belgium.

The Plague Abroad.—Cable despatches of March 13 state that with the exception of Mukden, the rate of mortality from the plague is decreasing in all the affected districts in Manchuria and China. Egypt reported 37 cases of plague, with 13 deaths, in the week ending February 10, while India reported 15,003 cases with 12,143 deaths in the week ending January 14. Russia has renewed her demand to be allowed to conduct the quarantine along the border and China has replied in favor of a dual quarantine, similar to that maintained in conjunction with the Japanese along the western boundary of Korea. The first cases of plague among hoofed animals are reported from the Fushan collieries, where bacilli were found in the carcasses of donkeys.

The Campaign Against Rats at Buenos Aires.—The *Semana Medica* opens the new year with the illustrated official report of the methods in use at Buenos Aires for extermination of rats. The work is centralized and squadrons are despatched to the premises to be attacked. They wall them off with sheet zinc and inside the buildings and yards use asphyxiating gases pumped into the rat-holes and tunnels through a hose from the generating cart or hand apparatus. The gas is produced by combustion of sulphur and arsenic or sulphurous acid gas is generated by the Marot apparatus which, the report says, is proving more and more valuable every day; it kills the rats and the insects on and about them while, properly managed, it is free from danger for the men and the building. A good rat dog is also regarded as indispensable for each squad of four men. The main point is to locate the actual breeding place, tracing the rats back from hole to hole until their permanent home is reached. The force of 100 men, supplemented by ten carpenters and masons, has become very efficient. The city is considered one of the most difficult to free from rats on account of the numerous livery and other stables and grain warehouses. The public garbage dumps are also great breeding places for rats; the dumps are now walled in with sheet zinc and incinerators are soon to be installed. The rats seem to prefer to make their permanent nests in vacant lots and gardens and particularly in chicken coops, near buildings to which they repair in search of food. The nests were sometimes found three feet and more underground. It is generally found necessary to take up part of the floor, to remove the rats asphyxiated by the gas. On suspicion of plague, cement is used to rat-proof the premises. The latest records given show from 12,000 to 14,000 rat holes thus cleared out each month with from 6,000 to nearly 9,000 rats killed. Dr. P. G. Rivero, who is in charge of the public health service which includes the deratization, does not approve of offering premiums for rat-killing, as untrained persons are not competent to exterminate the rats and in time of epidemics do not take precautions against infection from them, while there is danger that rats may be bred for the bounty. Poisons and traps are of little use.

CANADA

Club Election.—Dr. Adam H. Wright has been elected president of the Æsculapian Club, Toronto; Dr. George Elliott, secretary and Dr. Edmund E. King, treasurer.

Militia Surgeons Elect.—The medical officers of the militia of Canada met in Ottawa on February 24. Major Edward A. Lebel, Quebec, was elected president and Captain L. S. MacKid, Calgary, Alta, secretary.

New Medical Journal.—The *Western Medical News* appeared in January as the successor of the *Saskatchewan Medical Journal*. The new journal is announced as the official organ of the Alberta and Saskatchewan medical associations.

Medical Reciprocity.—In a bill which will shortly be presented to the legislature by Mr. Mousseau of Soulanges, the endeavor is made to place medical men in the Province of Quebec and other provinces on an equal footing, providing these provinces accept medical certificates issued in Quebec. At present there is no reciprocity between the various provinces of the dominion.

Hospital News.—The Vancouver, B. C., general hospital treated 4,184 patients in 1910 as against 3,042 in 1909. The number of patients admitted during that year was 3,983. The percentage of deaths was 5.87. The Montreal General Hospital treated in the wards 3,586 patients, an increase of 284 over the previous year. There were 272 deaths. In the out-door departments the total number treated amounted to 13,588.

Registration Legislation.—There is every prospect of the bill before the House of Commons to provide for Dominion Registration becoming a law. British Columbia, Saskatchewan and Alberta, which have no universities teaching medicine, cannot have any university representation on the Dominion Council, but two of the three councilors the Government will name, will be appointed from these provinces until the teaching of medicine is begun there.

Report on Tuberculosis.—The report of the Royal Commission on Tuberculosis appointed by the Quebec Government, has been presented to the Legislature. The document gives very explicit and definite recommendations as to the most practical and efficacious measures to adopt to combat the white plague. It is signed by Drs. Emmanuel P. Lachapelle, J. George Adami, both of Montreal; Michael J. Ahern, Quebec; Thomas G. Roddick, James J. Guerin, both of Montreal, and other prominent physicians of Quebec.

Personals.—Dr. Harry B. Anderson, Toronto, has gone abroad to work at the von Noorden clinic.——Dr. E. G. Kidd has been appointed chief of the anatomical department of Queen's University medical department, in succession to Dr. Frederick Etherington, Kingston.——Drs. Helen MacMurchy, Estella O. Smith, Frederick S. Minns, C. E. Hill, George A. Winters, F. G. Munn and William Morrison have been appointed assistant medical inspectors of schools in Toronto.——Dr. Charles H. Frooman, Winnipeg, late superintendent of the Manitoba Tuberculosis Hospital has been appointed superintendent of the Tranquille, B. C., institution.——Dr. J. Alexander Hutchison, chief surgeon of the Grand Trunk system, Montreal, is spending a holiday in the Mediterranean.

LONDON LETTER

(*From Our Regular Correspondent*)

London, Feb. 25, 1911.

Small-Pox in London

An outbreak of small-pox has occurred in the east end of London, and there are now twenty-five cases. The first patient was a Jewess, aged 12, who was admitted to the Mile-End Infirmary, February 5, after a few days' illness, suffering from an eruption. She was treated in one of the general wards till February 22, when the fact that other patients in the ward became ill led to a correct diagnosis. She was sent to the Small-Pox Hospital: soon after a patient from the same ward, a nurse, and a woman who scrubbed the ward were also sent to the Small-Pox Hospital. Another nurse was soon found to be affected. The nurses attacked had not been revaccinated. Three sisters of the first patient were found later to be affected with the disease. In all, eighteen cases arose in the infirmary. The ward in which the outbreak began has been isolated and its inmates have been detained under inspection for a fortnight. Every endeavor is being made to trace all persons who have been brought in contact with the disease, and extensive arrangements have been made for vaccination in the district. Small-pox in London shows great fluctuation. From time to time the disease is imported and gives rise to more or less serious epidemics. From 1885 to 1901 there was a period of comparative freedom, the number of cases falling as low as twenty-nine in 1899. In 1901 an epidemic of 1,700 cases occurred, which was followed by 7,796 in 1902. Since that year the disease has almost disappeared. In 1907 there were only eight cases and in 1908 four cases. In 1909 there were fifteen. The large number of unvaccinated persons, the result of the pernicious antivaccination campaign, is a cause of anxiety. The epidemic of 1901-2 gave a great impetus to vaccination, but this has now largely exhausted itself. In the locality of the present outbreak it is estimated that 32 per cent. of the children are unvaccinated.

Plague in India

The latest estimate of the ravages of plague in Manchuria gives 19,000 deaths in four months, and suggests comparison with India, where the disease has existed since 1896, and probably has caused no fewer than 9,000,000 deaths. In 1907 the death-roll culminated in the appalling figure of 1,300,000. Since that year there has been a remarkable decline. In the week ended Jan. 14, 1911, there were 12,943 deaths, and in the following week there were 20,157. There is one great difference between the pandemic in India and in Manchuria. In the former country the disease has taken the bubonic form, in the latter the pneumonic, and is, therefore, hardly less fatal to Europeans than to Asiatics. But, as the figures show, plague in India is much more deadly. Again, pneumonic plague is a winter disease, while the bubonic form increases during the first three or four months of the year and reaches a maximum in March or April.

The Eating of Cordite

During the late South African war a new drug habit came to light. Owing to the dearth of matches, the soldiers got into the habit of using the little rods of the new explosive, cordite, with which their cartridges were loaded, in order to light their pipes. By igniting one at a comrade's pipe other pipes could be lighted. Some of the men found that inhalation of the fumes of burning cordite had a narcotic effect. This led to the taking of cordite by the mouth, either solid or dissolved in tea. In those unaccustomed to the drug, even a small dose causes most unpleasant symptoms, chiefly severe headache, but those accustomed to the drug can swallow the whole contents of a cartridge. The face flushes, the head seems to swell, and after about a quarter of an hour the subject falls into a deep sleep. On awaking he suffers from thirst and headache. When taken in hot tea, cordite produces delirium, followed by sleep. Opium and alcohol taken in small quantities are used as "pick-me-ups" after cordite eating; and, inversely, cordite is used as a reviver after alcoholic intoxication. From the long use of cordite optic and mental delusions, timidity, weakness and a general breakdown, moral and physical, result.

Another Expedition Despatched by the Liverpool School of Tropical Medicine

The Liverpool School of Tropical Medicine has despatched its twenty-seventh expedition to Gambia and Senegal to investigate sleeping sickness. The members of the expedition are Prof. J. M. Todd, Dr. Wolbach of Harvard University and Mr. E. D. Todd.

Bonesetter Successfully Sued for Negligence

Mr. H. A. Barker, the well-known "bonesetter," and the successor of Hutton and Atkinson, has been successfully sued for negligence. For years he has been carrying on a large business. Extensive advertising has rendered his name a household word; the "oblique" form of advertising, in the shape of interviews illustrated with his portrait, which have appeared in the leading journals, has been largely used. He can boast of as large and fashionable clientèle as any leading surgeon. Indeed, in cases of bone and joint trouble, when dissatisfied with the advice of a great surgeon, many patients have resorted to Mr. Barker. Among athletes and football players he has a great reputation and is said usually to be consulted by them for injuries received in their pursuits. His methods are entirely manipulative, and, no doubt, prove successful in suitable cases. But the ignorant vaunting of a form of treatment, good for certain conditions, for every condition which human credulity will accept, has its dangers.

A man, aged 24, brought an action against Mr. Barker. In 1906 he twisted his [illegible] from a diving-board. From time to time [illegible] from weakness, stiffness and pain in [illegible] he consulted Mr. Barker, who said it was a very bad case, but promised him a cure. Barker first ordered radiant-heat baths. On Nov. 25, 1909, he performed some manipulations under gas. For some time afterward there was slight improvement, and the knee could be moved better, but then the pain returned and he again suggested baths. On December 16 further manipulations were performed under anesthesia. Ten days later an ulcer appeared over the knees. Medical advice was then sought and the knee was found to be tuberculous, and the ulcer due to the extension of the tuberculosis produced by the manipulation. There was a sinus extending to the interior of the joint, and the latter was not only tuberculous, but septic. To save the man's life amputation was necessary. A letter was sent to the defendant by the plaintiff's solicitors claiming damages. To this he made the extraordinary reply that he treated the case on condition that he undertook no responsibility—a statement contradicted by the plaintiff. For the defendant it was stated that he had attended 30,000 cases, was a perfect genius at his profession, and cured 94 per cent. of his patients. He denied that he manipulated the joint, and alleged that the anesthetic was administered only for purposes of examination. But the eminent surgeons who gave evidence for the plaintiff said that to administer an anesthetic for examination of the knee was both unnecessary and improper. In his evidence the defendant said that when he first saw the plaintiff there was extensive tuberculous disease, the hamstrings were contracted, and the tibia was displaced backward on the femur and flexed at an angle of 40 degrees. For the defendant, Mr. Whitehead, the well-known Manchester surgeon, said that he examined the amputated leg, and that the knee must have been in hopeless condition when the man first consulted Mr. Barker. The jury gave verdict of $100 for the plaintiff (a small sum under the condition), —probably because they thought that he was to blame for taking unqualified advice.

A New Departure in Medical Defense

There are two societies for medical defense in Great Britain - the London and Counties Medical Protection Association and the Medical Defense Union. For an annual payment of $2.50 these societies undertake to provide legal defense for a physician who may have an action brought against him for anything done in his professional work. Unfortunately, it is not uncommon for unscrupulous or dissatisfied patients to bring action against physicians for negligence in treating them. Such patients usually have no money and obtain the services of some speculative lawyer who will take the case on a contingent fee. Even when the physician wins, he is liable to incur the heavy legal expenses of defending the case, because the plaintiff has nothing. Until the medical protection societies were started, a physician was thus practically at the mercy of poor and unscrupulous patients. If the physician loses the case, all that the societies have done in the past is to pay the cost of the defense, leaving him liable for any damages obtained against him, as well as the costs of the other side. After a discussion extending over several years, the London and Counties Medical Protection Association has made a new departure and has undertaken to pay the costs of the other side in case the doctor loses, as well as any damages obtained against him not exceeding $10,000 in any one year. For these increased benefits it has been found necessary to increase the annual subscription from $2.50 to $5.

PARIS LETTER

(From Our Regular Correspondent)

Paris, Feb. 24, 1911.

Adult Mortality in France

The government commission on mortality, presided over by Professor Lannelongue, who is also a senator, reports that in France, as in most civilized countries, the adult death-rate is continually being lowered. The death-rate from transmissible and avoidable diseases has become continually smaller, both absolutely and relatively to the general death-rate. The tuberculosis death-rate alone, though it does not appear to be increasing, remains stationary and amounts sometimes to a fifth, sometimes a fourth, of the total death-rate. Prophylactic measures are therefore recommended, especially such as check the progress of alcoholism and give aid to the victims of tuberculosis at the first appearance of symptoms.

An International Sanitary Conference at Paris

The French government has just addressed to the countries of the two continents invitations to take part in an international sanitary conference at Paris next May. The conference was decided on in view of the epidemic of cholera last year in certain parts of southern Italy and the pneumonic plague which is raging in Manchuria, the frightful conditions of which recall the worst days of the epidemic in the Indies. The last sanitary conference on cholera, plague and yellow fever was held Dec. 3, 1903. Seven years constitute, as the government says, a long period to allow the matter to be in abeyance, especially in our days, when the progress of science and the diffusion of methods resulting from it are particularly rapid.

In order to facilitate as much as possible the task of the future conference, the French government has had the bases of the discussion prepared by the permanent committee of the international office of public hygiene (The Journal, Nov. 21, 1908, p. 1794). This committee, since 1907, when it was formed in Paris, has been accumulating and publishing the most complete information possible on all questions of sanitary organization. As soon as the conclusions of the permanent committee on the subject-matter of the future conference have been formulated they will be communicated to all the governments invited to the conference for their use in preparing their contributions.

A Proposition for the Reform of Medical Education

Dr. Lannelongue, professor at the Faculté de médecine de Paris and senator, has proposed to the senatorial commission of higher education to make the medical teaching body distinct from the examining body, for the following reasons: Medical instructors are overworked and it is important to relieve the professor from the drudgery of examinations which prevent him from doing justice to his pupils or contributing to the advancement of science. An examination conducted by an outsider would necessarily be more impartial. The pupil would not be tempted to try to secure good marks by studying the personal predilections of his professor. Lannelongue believes that it would be easy to secure a corps of competent examiners in the great university centers by utilizing the services of the numerous *agrégés libres*. The *agrégé* professors, it should be explained, are appointed for a period of only nine years. After the lapse of this time they become *agrégés libres;* that is, they no longer form a part of the teaching corps. Their anomalous situation has often aroused keen criticism. In the rôle of examiner they might find the normal employment of their knowledge.

Limitation of the Number of Physicians

At the last meeting of the Association de la presse médicale française the question of the limitation of the number of physicians was discussed. The same question will soon be taken up by the vigilance committee of the Congrès des praticiens. The members present unanimously empowered their delegate to reject the limitation but to demand a due severity in examinations and sufficient preliminary qualifications in the way of general education, such as classical studies, before permitting candidates to undertake medical studies.

Memorial to Dr. Mesny, a Victim of the Plague

The minister of war has just received the report of our military attaché in China in regard to the circumstances of the death of Dr. Gerald Mesny, physician of the colonial troops, who died of the plague at Harbin, January 13, last, and whose name was incorrectly given in the first despatches as Meunier. Dr. Mesny was a professor in the Chinese medical school at Tien-Tsin when the plague broke out in Manchuria. The authorities asked him to organize measures of defense. He did not hesitate to leave his wife and children to put himself at the head of the Chinese physicians, and went to meet his death at Harbin. When stricken with the plague, he gave evidence of real heroism. In an interview with the French consular agent he declared that, according to all probability, he had still two days to live, and added, smiling, "I do not say au revoir but adieu."

The director [illegible] du service de santé des troupes colo[illegible] facts to the students, declared that he had decided that Dr. Mesny's name should be inscribed on the marble tablets of the school devoted to the officers of the sanitary corps of the colonial troops whose death is the result of devotion to duty.

BERLIN LETTER

(From Our Regular Correspondent)

BERLIN, Feb. 24, 1911.

Personal

Professor Uhlenhuth has accepted a call as director of the hygienic institute at Strasburg.——The report has been repeatedly circulated by the newspapers that Waldeyer contemplates resigning during this year. As I am reliably informed, this statement is not correct. Although the distinguished anatomist enjoys an enviable vigor in spite of his 75 years, nevertheless. it would seem that consideration for the rising generation would justify professors of his age in retiring.

The Plague

According to the latest information, the plague in China is receding and it is to be hoped that Europe in general and Germany in particular will be spared from its visitation. For the present the German government has not seen fit to establish any special regulations aside from the ordinary quarantine requirements for ships. The Imperial Health Council, the *Reichsgesundheitsrat*, met to discuss the question Feb. 14, without adopting any definite measures. No plan has been so far developed by the officials for sending German physicians into the plague district.

Improvement of the "Practical Year"

As you are aware, medical students in Germany after they have passed their state examination are required to spend a year for practical education at the university clinics and hospitals, and are only licensed as physicians when they have successfully complied with this requirement which is certified to by the director of the hospital. This arrangement, which has existed for some years, has shown various defects which have constantly become more evident. During the "practical year" they bear the name of "medical practicants" (*Medizinalpraktikant*). The medical councils (*Aerztekammer*) have considered this matter and have reached the conclusion that the institution must be improved. The difficulty consists essentially in an insufficient opportunity for independent activity, an excessive number and unsuitable selection of the hospitals which are qualified for the reception for practicants, the constantly increasing employment of the medical practicants as assistants, and their insufficient instruction in social medicine. The employment of medical practicants in place of assistants has led to complaints by many hospital directors because on that account a lack of actual assistants has arisen. Many young physicians used to feel the need of supplementing their practical education by service as assistant, for one or more years, but now the medical practicants believe that they have sufficiently fulfilled the demands for practical education by their work as assistants during the practical year. In consequence of these difficulties the minister has required the provincial officers to institute an investigation into the training and work of the practicants and make a report on the matter. There is no doubt that the government will endeavor to remove the causes of complaint.

Official Supervision of Homes for Toilers

An important institution for improving the public health will begin its practical activity in Charlottenburg, March 1. In order to remove housing conditions which are insanitary and unsatisfactory in moral and other respects, an inspection service for all small dwellings in which sleeping rooms exist is to be established. This shall also control the permits for laborers, factory hands, apprentices and servants to sleep in the houses of their employers. For the performance of this service two house inspectors are to be appointed by the city and their number will be increased later. These officials with the aid of two assistants from the housing office are to examine all suspected houses, to ascertain if they meet all sanitary and building requirements and if this is not the case to see that the defects are remedied. An information bureau for dwellings is to be associated with the housing office. This is to make possible a substitute for each dwelling that is found insanitary. Together with the inspection of dwellings and the information bureau, a department for statistics in regard to housing is to be established. If this shows a deficiency of sanitary apartments, the care for housing must be extended and provision must be made for the erection of suitable houses which will assure sanitary dwellings to people of small means. With the establishment of this housing office the city of Charlottenburg has instituted a philanthropic enterprise which may serve as a model.

Cancer Statistics in Bavaria

Bavaria has just published the official statistics with reference to cancer collected in 1909. Dr. Teilhaber of Munich gives some results of the investigation in the last number of the *Münchener medizinische Wochenschrift*. According to the figures cancer of the rectum appears to affect in particular those engaged in office work and professors, and secondarily carpenters and tailors. Teilhaber considers that congestion in the pelvic organs is responsible for this predilection. Cancer of the stomach is especially a disease of the poorer population and particularly in Bavaria the peasant class are especially affected by it. From this Dr. Teilhaber draws the conclusion that advancing civilization cannot constitute a cause for the appearance of cancer, for the Bavarian peasants live under the simplest conditions. Cancer of the face is chiefly found in persons who do work in the open air. The conclusions of the author are of uncertain value because of the relatively small number of cases. Still the material thus obtained must be regarded as valuable since from it, in combination with more like material, it is probable that definite conclusions can be reached.

Cancer Statistics in Baden

On the authority of the Baden National Committee for Cancer Research a few years ago a new census of the cancer patients in Baden was undertaken. The material obtained in this way has been elaborated by Privat-Docent Dr. Werner, an assistant of Professor Czerny of Heidelberg, and he has reached some results which, although they deal with comparatively limited material and must, therefore, be accepted with caution, appear to be of interest in several particulars. The distribution of cancer in the individual communities is shown to differ widely. Werner tries to draw conclusions from this fact with reference to the etiology of cancer and he recognizes five factors: heredity, inbreeding, occupation, mode of life (especially nutrition) and race.

Hereditary taint appears to play no great rôle, according to the Baden statistics, but the author emphasizes the fact that the data do not permit any decisive conclusion on account of their meagerness and uncertainty. Inbreeding seems to have no significance in the etiology of cancer, but more careful study of this question is also desirable. The communities in which consanguineous marriages are common, so far as known to the author, are not the ones in which cancer is specially prevalent. As to occupation, a great increase is found in the groups of men servants and day laborers, without reference to age. Similar conditions in this respect were found by another investigator in the statistics of cancer in the kingdom of Saxony. Nevertheless the author holds this finding of no essential importance in determining the etiology of cancer.

He considers that it would be much more reasonable to determine the occupation in families in which cancer is rare or especially prevalent in order to determine whether occupations which produce certain injuries or which bring the worker in contact with certain objects or animals are responsible for the frequency of cancer or whether certain occupations are frequent among cancer patients because they are chiefly followed in regions where cancer is prevalent. The ordinary differences in nutritive conditions as between city and country, agricultural and manufacturing communities, winegrowing districts and other localities show no corresponding differences in the death-rate from cancer.

As for the contagiousness of cancer, no especial frequency is found in cases where a considerable number of persons live in narrow quarters, from which Werner draws the conclusion that direct contact plays but a slight rôle in the causation of cancer. Neither could a special predisposition of any race be established. The same is true for the influence of the place of residence and the housing conditions. The influence of climate on cancer mortality is also negative. Neither could any parallelism be discovered between the distribution of the higher animal and plant species and the occurrence of cancer, so that the assumption of Behla, which was in itself very unlikely, is shown to be fallacious. The supposition that the parasites of cancer are conveyed by stinging insects is not sustained. No parallel could be traced between the distribution of human and animal cancers.

Altogether, Werner concludes from his statistical investigations that there must be assumed to exist some locally prevalent factors, not connected with the age of the person, which occasion or favor the occurrence of cancer and depend on the character of the locality rather than on that of the inhabitants. As to the question whether the frequency of cancer and the danger of acquiring it are increasing, Werner believes that we must admit an actual increase in the disease, although much of the increase shown by statistics must be attributed to better diagnosis, greater supervision of the population by physicians, better opportunities for observation in hospitals, etc.

VIENNA LETTER

(From Our Regular Correspondent)

Vienna, Feb. 23, 1911.

Unexpected Help for Medical Institutions

The danger threatening the Viennese medical institutions from political parties that wish to control them has been averted, at least for some time, by an unexpected occurrence. The government has come into possession of some 25,000,000 kronen ($5,000,000), as the tax to be paid on the estate left by the late Baron Rothschild on his sudden death quite recently amounts to at least this sum. Out of this tax, the hospital fund must receive 24 per cent., or about 6,000,000 kronen. This will be sufficient to pay the deficit of this fund and also to stop any controversy as to responsibility for hospital relief to the poor, a fruitful source of interference for the above-mentioned political parties. The deceased, a member of one of the wealthiest private banking houses of Europe, has also left liberal legacies to various charitable institutes, so that these at least will have no need to appeal to the public corporations for help; another obstacle for political enterprise.

The Successor of Strümpell: A Recommendation by the Faculty

To-day a meeting of the professors of the medical faculty of Vienna took place, in which a special committee published the names of the professors it recommended as eligible to the appointment to the third medical clinic. Professor von Noorden had studied the problems connected with the affair. When von Strümpell suddenly resigned his post here, and went to Leipsic, in the place of Curschmann, the reasons given for his abrupt termination of an appointment were so serious that a most unpleasant controversy ensued. The medical faculty was justly offended at the manner the professor had been treated by the responsible officials, and for some time the relations between government and university were strained. When in December the possibility of the clinics becoming a domain of political influences was imminent, the faculty refrained from making the necessary recommendation of a competent successor, as it did not want to bind a first-class man to unstable conditions. After certain guarantees had been given by the government concerning the liberty of teaching and the independence of the clinics, the faculty reconsidered its position, and recommended the following candidates, who are named in the order of preference: Prof. Herman Sahli (Berne); Prof. E. von Romberg (at present in Tübingen), and two Austrians, Prof. F. Chvostek (Vienna) and M. Ortner (in Innsbruck). There is a certain tendency in the government circles to exclude candidates from Germany, since there are already several men here from that country, and because of the affair with Strümpell, who also came from that country. It is therefore probable that an Austrian will be appointed, and of the two the better chances are with Ortner.

Miscellany

Symptoms of Exophthalmic Goiter in Pulmonary Tuberculosis.—F. Bialokur noted Basedow symptoms in twenty-seven of 337 patients with pulmonary tuberculosis during 1908, and in twenty-eight in 1909. He tabulates the details of ten typical cases, remarking that the Basedow symptoms must be often overlooked in such cases elsewhere or ascribed to the tuberculous infection. The connection between the Basedow symptoms and the tuberculosis is more than casual, as is shown by the benefit that follows treatment addressed to the exophthalmic syndrome. As this improves, the pulmonary symptoms subside and the patient may be clinically cured. There is probably a vicious circle, the tuberculous toxin exerting an injurious influence on the thyroid, stimulating it to increased secretion, and this secretion may enhance the virulence of the tubercle bacilli, which, in turn, may rouse latent lesions into active processes. In his experience, every patient with exophthalmic goiter was already tuberculous; other physicians seldom examine the lungs with sufficient care with Basedow patients, as their attention is concentrated too exclusively on the exophthalmic goiter. When enlargement of the thyroid is discovered with pulmonary tuberculosis measures to reduce it to normal size should be instituted at once, as thyroid functioning impresses a special character on the course of the tuberculosis. The changes in the lungs are of different kinds, and there may be great destruction, but, as a whole, the lesions are not the most malignant; obstinate diarrhea is the rule; the thyroid is not much enlarged and pronounced exophthalmos is rare; the patients are gloomy and despairing instead of the hopefulness common with tuberculosis. There is generally a tendency to sweats and the temperature is usually subfebrile, the urine normal. It is difficult to find any tubercle bacilli in the sputum, so that the trouble seems to be bronchitis rather than tuberculosis. The overwhelming majority of his patients were women. Pregnancies recurred with remarkably brief intervals, and the sexual instinct was strong and the menses abnormally frequent and profuse. In the ten typical cases described in detail besides the usual strychnin, arsenic or iron treatment, he exposed the thyroid to the Roentgen rays or had it removed. One man of 56 had had the Basedow syndrome and pulmonary tuberculosis for twelve years, and his daughter the same for four. Both were clinically cured by thyroidectomy. Bialokur's article was published in the *Zeitschrift für Tuberkulose*, 1910, xvi, 567.

Social Hygiene in Its Pedagogic Aspects.—A knowledge of the function of reproduction and a proper attitude of mind regarding it must be recognized by educators to be a necessary part of the equipment of every young person for life, says W. S. Hall (*Journal of Preventive Medicine*, February, 1911). Parents and teachers are morally bound to treat all questions of sex in the same simple, straightforward, truthful way that other life problems are treated. Responsibility for instruction of the young in sexual development and sexual right living should rest on parents; but as a rule parents do not discharge this responsibility, and therefore it devolves on the physician and the educator, and the societies formed for the purpose of educating the public on moral and social prophylaxis. The important lesson learned by Hall from years of experience in teaching emphasizes the importance of segregation of the classes to whom he talks. Boy hearers should be separated from men; mothers should be separated from fathers; mothers and daughters should be addressed in separate audiences. The more homogeneous the audience the more definite and positive can the statement of the speaker be. It is easy to see that in an address to a mixed audience of parents and children, sex problems would have to be discussed in a most general and indefinite way. The circumlocutions would have to be so veiled and the allusions so remote that they would be understood only by the most intelligent, and would probably be grossly misunderstood by the less intelligent and experienced. If the audiences were separated into the boys and men, and the women and girls, the situation would be somewhat better, but not wholly corrected. Concerning a division of the audience on age lines, the sexes being mixed, Hall's experience is that a speaker, particularly a physician, can talk much more freely to an audience of mothers than to a mixed audience of mothers and fathers. A frank statement of certain subjects in the daily journal, or in journals of hygiene, is a valuable method of imparting information, as they are read by the individual and here we have segregation carried to its ideal limit. Hall then discusses the matter to be presented to classes of boys or girls of different ages, and refers to the broader range of facts which may obviously be presented to parents. Hall has used three methods of presentation—the biologic, the moral and the heroic. The biologic is the ideal method of presenting the subject of reproduction and sexual life, but is feasible only for the teacher of biology of a high school or college, and is out of the question for social workers, physical directors and public lecturers. The moral method, an appeal, from a moral standpoint, for right living, Hall found to be not effective. The heroic method is based on the human instinct for hero worship. One can get hold of an audience of boys by a discussion of some of the world's great heroes, and will have their undivided, almost painful attention, when he asks the questions: What is the secret of manhood? And: What can a boy do to grow into the highest type of virile manhood, which alone makes possible heroic deeds? Hall says that the lecturer can answer that question in the last five minutes of a forty-five minute talk, and leave every boy in the audience convinced and determined. He is convinced that incomparably the most effective method of presenting these matters to young people and parents, is a frank presentation of the findings of science. Don't try, he says, to point too many morals. If the presentation has been clear and convincing, the listeners will readily draw their own conclusions and formulate their own morals.

A Method for Determining the Absolute Pressure of the Cerebrospinal Fluid.—M. A. Cassidy and C. M. Page (*Proc. Roy. Soc. Med.*, January, 1911), have devised a simple apparatus for determining the absolute pressure of the cerebrospinal fluid with the escape of only an inappreciable and constant volume of the fluid. It consists of a hollow needle of 1.5 mm. bore, provided with a close-fitting stylet, the pointed ends of both of which are cut at an angle of about 35 degrees. Two cm. from the blunt end of the needle there is a simple cock. Into the lumen of the needle beyond this cock can be fitted a tapped nozzle, which is connected to an open glass tube 18 cm. in length and 15 mm. in diameter by means of rubber pressure tubing 1 meter in length. A wooden clip to which is attached a measuring tape can be fixed to any point of this glass tube. In order to take a reading the following technic is observed: After sterilizing the apparatus the patient is placed on the side with the lumbar spine well flexed, with the cerebrospinal axis horizontal. Normal saline solution at 120 F. is poured into the glass tube and pressure tubing, and the tap on the nozzle is closed when the glass tube is half full of the solution; the wooden clip is then fixed on the glass tube to mark the level of the saline solution. The theca is punctured through one of the lumbar spaces, the needle being introduced exactly in the middle line and perpendicular to the coronal plane; the stylet is withdrawn and the cock is closed as soon as the cerebrospinal fluid appears at the orifice of the needle; not more than a drop or two should be lost. The pressure tubing is then connected to the needle by means of its nozzle, and the glass tube is held so that the level of the fluid in it is at a height above the needle roughly equal to the expected reading. Both the taps, that is, that on the needle and that on the nozzle, are now opened so that the saline solution may be balanced against the cerebrospinal pressure. If the latter is greater than the height of the saline solution, fluid will rise above the level of the wooden clip, and vice versa. The glass tube is quickly raised or lowered, as may be necessary to keep the contained solution at its original level; the vertical height of the clip above the needle will then give the intrathecal pressure in terms of centimeters of normal saline solution. The density of normal saline solution at 120 F. is almost identical with that of water. When proper communication has been established between the saline solution in the tube and the cerebrospinal fluid, a regular rise and fall in the pressure to the extent of about 1 cm. will be observed, synchronous with the respiratory movements; unless this respiratory excursion is present no reading is of value. The method has been used in over sixty cases. The highest pressure observed by Cassidy and Page was 100 cm. saline in a case of cerebral abscess, and the lowest 7 cm. in a case of diabetes insipidus.

Fallacies Regarding the Transmission of Infectious Diseases.—With the establishment of the germ theory and the discovery of certain organisms always present in certain diseases we began to reconstruct our ideas regarding the manner with which these diseases are spread and new ways of prevention and cure are sought. B. R. Rickards (*Quar. Bull., Ohio State Board of Health*, October-December, 1910) says that old ideas in regard to the transmission of infectious diseases are hard to eradicate. Diphtheria, prior to the discovery of the Klebs-Loeffler bacillus, was supposed to have some connection with sewer gas or broken drains, and wherever a case of diphtheria was found a faulty trap or other imperfection was hunted for and usually found. We know now that the diphtheria bacillus is not found in the air or soil of drains. The only significance of the sewer-gas theory is that continually breathing such gas lowers the vitality and renders the person more liable to infection. It is now generally believed that diphtheria is almost always conveyed from mouth to mouth by means of kissing, public drinking cups, spoons, gum, etc. It seems probable that diphtheria is not conveyed by clothing, wall paper or other inanimate objects, except perhaps articles like handkerchiefs. It may be conveyed from persons who are perfectly well, who harbor diphtheria germs in their throats, but who possess sufficient resistance to prevent the development of the disease in themselves. Typhoid fever was formerly supposed to originate from filth such as decaying garbage, etc. This conception contained a grain of truth, but not the whole truth. Filth does serve as a breeding-place for flies, which are active spreaders of disease, including typhoid fever. The disease cannot originate except from a previous case and rural wells are only sources of typhoid when they are contaminated by human excrement from a patient with typhoid fever. It has been believed that street dust infected by spitting, infected rooms, milk from tuberculous cows and the like, are factors in spreading tuberculosis, and this is perhaps true to a certain extent. Experiments conducted by Rickards and others tend to show that heavily-infected sputum is rendered harmless in an apparently short time by the effect of the sun, and that after drying sufficiently so that it can be blown about as dust, the germs will be destroyed. Infected rooms undoubtedly play a larger part, as direct sunlight cannot reach all parts of the rooms and reflected light has a slower destructive action on the germs. The milk from cows is no doubt responsible for some tuberculous infection, but to a lesser degree perhaps than are human sources. The milk becomes infected most frequently from the excrement and it is probable that in babies the infection is most frequently communicated by kissing or by feeding utensils. What has been said regarding these common diseases applies also to such infections as measles, scarlet fever, small-pox, etc. Rickards urges that in the work of combating infectious diseases we should abandon exploded theories and get down to the actual facts and modify our quarantine and other measures accordingly.

Unusual Complications of Chronic Nephritis.—A. Pollak reports some interesting cases in the *Wiener klinische Rundschau*, 1910, xxiv, showing that pleurisy, pericarditis, peritonitis and even meningitis may develop as a complication of chronic nephritis. Also that in the stage before actual uremia, symmetrical fibrillary twitching may be observed or a syndrome suggesting multiple sclerosis and hysteria. In one case acute peritonitis developed in the course of a mild chronic nephritis in a middle-aged man. In another case acute meningitis developed in a woman of 47 with signs of nephritis. He has encountered three cases of the complicating pericarditis. In all the above cases the serous membrane became suddenly affected in the midst of apparent health except for the mild nephritis. All the patients died except one man who passed through two attacks of the pericarditis and succumbed a few months later to a heart lesion. In another case a woman of 56 with chronic nephritis began to notice fibrillary twitching in the extremities. In a few days a typical attack of uremia followed in which the patient succumbed. Another patient was a young woman who complained of headache frequently recurring during the last four months. Physical examination was negative but he urged the patient and her mother to send him some urine for examination. Under tonics the young woman's symptoms subsided and she neglected to send the urine. Nearly a year afterward he was called in again and found the young woman with severe symptoms suggesting multiple sclerosis. Two days after this rapidly fatal uremia cleared up the diagnosis. It is rarely, he says, that chronic nephritis runs its course in this way without attracting attention to the kidneys. If his warnings in regard to urine examination had been heeded, the nephritis might have been detected and treated in time. In another case a little girl grew pale and the medical inspector of the school found dulness over the right apex and râles, and gave directions for general treatment of tuberculosis. He sent the child to a lung specialist a week later who confirmed his diagnosis. and referred the child to Pollak for a certificate entitling her to a course in a sanatorium for lung affections. Pollak examined the urine and found 2 per cent. albumin with tube-casts and red corpuscles; the child died in six weeks. He comments that this case speaks volumes for the necessity of medical school inspectors confining themselves to mere detection of illness and warning the parents that the child is sick and should be taken to a physician. The physician can then make an examination much more thoroughly than is possible in the school, and institute appropriate measures in time.

Sanitary Food Production.—Declaring that food, though chemically pure, may be sanitarily unfit to eat, H. E. Barnard, State Food and Drug Commissioner of Indiana, in an address delivered before the Association of State and National Dairy Departments, at New Orleans in December, 1910, stated his belief that this fact will be the basis of future food legislation, and that the work of the food departments, commissioners and inspectors will be less and less given to controversial discussions of labels and manufacturers, and instead will be devoted to the promulgation of the old maxim in a new version. "cleanliness is godliness," among food producers and distributors. To him the astonishing thing is that for so many years we have trailed after the milk wagon in search of watered samples, and never entered the dairy to hunt the reason why the infant mortality of our cities is ten times as high among bottle-fed as among breast-fed infants; that we have frantically fought the rainbow-hued demon whose dye-pot made strawberry pop, jellies and confectioneries esthetically attractive, forgetting in the fray that polluted water in the pop bottle is a thousand times more dangerous to the consumer than anilin red, and that rotten fruit is a worse adulterant of jam than an atom of Biebricht scarlet; that we have fought relentlessly the substitution of oleomargarin for butter on the boarding-house table and never made a move to prevent the sale for food of rancid, filthy country butter, infinitely worse for the consumer and a more vigorous competitor of the product of the trained buttermaker than all the oleomargarin factories in the country. The fact faces us that the grocer who is honest but dirty strikes a more direct blow at the health of the community than his competitor, who does not hesitate to sell distilled water for cider vinegar and cotton-seed oil for olive oil, but who in the commission of his crimes sees to it that his hands are sanitarily clean, his goods free from dust, and his clerks undiseased; and that the butcher who sells tuberculous meat is infinitely more dangerous than he who mixes stearin in his lard or puts cracker crumbs in his sausage. The one class robs us of our heritage of health; the other steals but the lining of our pocket-books.

Report of Loomis Sanatorium.—The 1910 report of Loomis Sanatorium, Liberty, N. Y., for the treatment of tuberculosis, shows that 416 patients were admitted during the year and 411 discharged. The physician in chief, in summing up the work of the year, emphasizes the fact, to which attention was called in the report for 1909, of the undoubted relation between the length of stay in the sanatorium and the result of treatment, at least so far as the class of "apparent cures" is concerned. Thus, in 1907, with an average stay in the institution of 31.44 weeks there were 18.80 per cent. of apparent cures; in 1908, with an average stay of 43.09 weeks, the apparent cures were 21.52 per cent.; in 1909, with an average stay of thirty weeks, the apparent cures were 15.61 per cent.; while in 1910 the average stay was 26.62 weeks and the apparent cures amounted to but 12.30 per cent. This relation is also borne out in the class of incipient cases. In 1908, for instance, 72 per cent. of incipient cases were discharged as apparently cured, after an average residence of 25.83 weeks; in 1909, but 43.75 per cent. after a stay of 19.62 weeks, and about 50 per cent. in 1910 after an average residence of 19.66 weeks. It is found that this applies not only to the immediate results, but has a bearing on the ultimate results after the patient leaves the sanatorium. Forty-nine patients received tuberculin treatment in addition to the other measures, thirty-three of these for a period exceeding ninety days. One died. All the rest were improved, arrested or apparently cured. Following out the plan conceived and mentioned in the report for 1909, a more scientific method of feeding the patients has been followed during the past year. Careful weighing of the food, and computation of the chemical constituents, and more extended experience have permitted the division of the patients into three classes with regard to their diet, with the result of securing a diet more nearly adapted to the individual requirements, with consequent greater benefit to the patients. The report still further confirms the conclusion that the sanatorium treatment of tuberculosis presents great advantages over any other plan.

Pregnancy After Nephrectomy.—At the recent annual meeting of the French Société d'obstétrique, de gynécologie et de pédiatrie, several members reported cases of apparently normal pregnancy in women who had had one kidney removed on account of tuberculosis. Pinard, Pousson and Hartmann reported experiences in this line, the total on record, according to them, being now 113 cases in which an operation on the kidney for tuberculosis or other cause was accompanied or followed by a pregnancy. In the thirty-five cases in which the operation was done on the pregnant woman, the pregnancy did not seem to be affected in any way and it did not render the prognosis of the kidney operation any more serious. In seventy-four other cases the women became pregnant after the nephrectomy. With the exception of one woman who died from eclampsia and another from renal insufficiency during the puerperium, the single kidney answered every purpose, although it was itself diseased in a few cases and delivery had been difficult in a few others on account of contracted pelvis or other cause. In three cases the pregnancy followed nephrotomy; it terminated in abortion in one case but the other patients had two and three normal pregnancies. In another case a normal pregnancy followed bilateral decapsulation of the kidney. The conclusions were that even when the kidney has been removed for tuberculosis, if the urine is free from bacilli, marriage may be permitted to girls. Pousson stated that fifty-nine out of sixty-five women on whose kidneys he had operated have passed through a normal pregnancy since and some three pregnancies. In seven others there was abortion. In every instance the puerperium was free from complications, and most of the women could nurse their children, one becoming a professional wet-nurse. The children were all healthy at birth and to date, except that one has died of whooping-cough and another at the age of 15 months of tuberculous meningitis.

Conservative Treatment of Total Rupture of Lower Segment of Uterus.—A. Boero, Buenos Aires, in a communication to the *Semana Medica*, 1910, xvii, 1657, reviews the indications in such cases and reports five cases from his own experience in which notwithstanding this serious complication of childbirth all the patients but one recovered. The aim is to refrain from anything that might increase the shock from which the woman is suffering. The uterine artery is rarely involved in the laceration and what hemorrhage there is comes from the site of the placenta. When there is no shock he removes the uterus at once, but in the severer cases he tries to tide the patient past the shock period and give her time to recuperate. A month or two later it is a comparatively simple matter to remove the whole or part of the uterus. The fetus is nearly always dead after such a rupture, he says, and it should be extracted with a mutilating operation if necessary to get it and the placenta out of the way as rapidly as possible, without version. There should be no rinsing out of the uterus or vagina. The obstetrician's hand is introduced and the lower lips of the upper segment are drawn together and held between the thumb and index finger and thus worked down inside the lower, torn-off segment; the fingers are then replaced by forceps and the upper segment is securely fitted into the lower segment, thus shutting off all communication between the vagina and uterus and the peritoneal cavity, except for a small tunnel made in the broad ligament for drainage, through which a wick of gauze is pushed. The lower segment and vagina are then packed with gauze. The obstetrician must realize that his hand is the vulnerable point in the procedure and that on his sterilization of his hands depends the outcome of the case. In the one fatal case in his experience several hours had elapsed after the rupture before the patient was brought to the clinic and various forceps applications had been made.

Loss of Appêtite in Tuberculosis.—B. Schleisick contributes an article on this subject to the *Zeitschrift für Tuberkulose* in which he states that the loss of appetite with a tuberculous pulmonary process may be the result of the action of toxins or of a latent tuberculous process in the cecum. The latter is more common than generally recognized; it may be discovered by systematic palpation, eliciting mild pain in the region. The diagnosis is confirmed by an injection of tuberculin which induces a typical focal reaction at this point. He adds that the tuberculous process in the cecum once diagnosed, operative treatment should follow at once, as tuberculosis of the intestines seldom heals spontaneously and in the appendix practically never. The operation is simple and easy at this early stage. Persistent lack of appetite may be the only sign of the intestinal process for a long time. Even the toxic anorexia may be favorably influenced by tuberculin treatment. The abnormal secretory conditions in the stomach return to normal under the influence of the tuberculin.

Soil Pollution by Hookworm.—Stiles and Gardner (Bulletin U. S. P. H. and M.-H. Service) have conducted experiments for the purpose of determining the length of time hookworm eggs may retain their vitality in the soil and under various conditions of drying and temperature. The soil under and around the privy is not entirely free from infection with hookworm even five months after the privy was last used, although the infection is considerably reduced at the end of four months. When the fecal material has undergone decomposition under water most of the hookworm eggs are dead in about ten weeks, though some still survive but they would probably all be dead in three months. It would not be safe to use such material as a fertilizer in less than three months. It has been shown that chlorid of lime fails to kill hookworm eggs in twenty-two to forty hours. The eggs of the typhoid fly and other species of fly are still capable of development after that length of time, and the flies are capable of reaching the open air even when material in which they breed has been buried under from 17 to 72 inches of sand.

American Achievements in the Tropics.—In declining an invitation to attend a banquet President Taft made this fine tribute: "We have real ground for national pride in the fact that England, France, Germany—Germany not so much so—and Holland have been engaged in the colonial business in the tropics for 100 years, some of them 200 years, and yet it remained for American physicians, and especially the physicians in the army to discover more things in the ten years since the Spanish-American War than were discovered in the whole two centuries before that time; and if nothing else justified the Spanish-American War, the discoveries of the American physicians since that time—what I may term the sequence of the war—were ample to justify the expenses of that war to ten times over. It is a real record of achievement of a national character that everyone who understands it must dwell on with sincere pride."

Marriages

Henry Francis Ballard, M.D., to Miss Louise Myers, both of Chenoa, Ill., February 22.

John Stephan Nagel, M.D., Chicago, to Miss Evelyn Morrison Robinson of New York City, March 7.

Edward Montgomery Wellbery, M.D., to Miss Rosemary Carney, both of Brooklyn, N. Y., February 28.

Bleeker J. Knapp, M.D., Evansville, Ind., to Miss Eleanor Dee Gordon of Madisonville, Ky., recently.

Martin Washington Yencer, M.D., Richmond, Ind., to Miss Jeanette Hill, at Richmond, February 23.

Preston Worley, M.D., Clovis, N. Mex., to Miss Ethel Audrey Kennedy of Youngstown, O., February 28.

Nathaniel H. Manring, M.D., Elwood, Ind., to Mrs. A. C. Gordon of Indianapolis, at Louisville, Oct. 31, 1910.

George Graham Hunter, M.D., Los Angeles, Cal., to Miss Grace Geraldine Hildreth, at Los Angeles, Dec. 20, 1910.

George Alfred Lawrence, M.D., to Mrs. Julia W. M. Curtis, both of New York City, at Wilmington, Del., February 14.

Frank Lossing Carpenter, M.D., Berkeley, Cal., to Mrs. Mary Saylor Bingham of Glens Falls, N. Y., at Oakland, Cal., February 1.

Deaths

Henry Pickering Bowditch, physiologist of world-wide fame, formerly dean of Harvard Medical School, died at his home in Jamaica Plain, Boston, March 13, aged 70. He was graduated from Harvard University with the degree of A.B. in 1861, and served during the Civil War in the Massachusetts Volunteer Cavalry, attaining to the rank of major. At the close of the war he entered Harvard Medical School and was graduated from that institution in 1868. He then pursued studies in his chosen branch of physiology for three years in Germany, and on his return to the United States in 1871 was made assistant professor of physiology in Harvard Medical School. From 1876 to 1903, he was professor of physiology in that institution, dean of the school from 1883 to 1893, and George Higginson professor of physiology from 1903 to 1906. He was given the honorary degree of D.S.C. by the University of Cambridge in 1898, and the degree of LL.D. by Edinburgh University in 1898, Toronto University in 1903, and the University of Pennsylvania in 1904. He was a member of the American Medical Association, American Academy of Arts and Sciences, National Academy of Sciences, American Philosophical Society, American Society of Naturalists, and American Physiological Society. In 1896 and 1900 he served as vice-president of the American Association for the Advancement of Science, and was also a corresponding member of the British Association for the Advancement of Science. Dr. Bowditch was a prolific writer on his specialty of physiology. Aside from his eminence as a scientist, Dr. Bowditch endeared himself to all who knew him by his character as a man; especially to his students was he the ideal of the scholar, the man, and the courteous, polished gentleman, and his influence in arousing in them a desire for thorough work and for living up to the highest ideals of the profession was great and permanent.

Daniel Augustus Currie, M.D. Buffalo (N. Y.) Medical College, 1864; a member of the Medical Society of the State of New Jersey; and of the Association of Military Surgeons of the United States; past president of the Alumni Association and for five years a trustee of the university; one of the organizers of the Englewood, N. J., Hospital; a member of the operating staff of the Hackensack Hospital; major-surgeon of the Fifth Infantry, N. G. N. J., and lieutenant colonel of the Second N. J. Infantry, U. S. V., during the Spanish-American War; local surgeon of the Erie Railroad; first mayor of Englewood, and afterward reelected to that office; died at his home, February 28, from cancer, aged 70.

Eugene Kingman, M.D. College of Physicians and Surgeons, New York City, 1870; a member of the American Medical Association, and Boston Society of Psychiatry and Neurology, and president of the Rhode Island Medical Society in 1910; neurologist to the Rhode Island Hospital; organizer and first chief of the staff of the Providence Lying-In Hospital; a charter member and first president of the Rhode Island Hospital Club; died at his home, February 26, from uremia, aged 67.

Albert Joseph Erdman, M.D. Jefferson Medical College, 1873; a member of the Medical Society of the State of Pennsylvania, and formerly president and treasurer of the Lehigh County Medical Society; for seven years a member of the local pension examining board; for several years school director of Allentown, and for thirteen years physician to the Lehigh County Almshouse; died at his home in Allentown, March 1, from cerebral hemorrhage, aged 58.

Bartlett Norton Torrey, M.D. Washington University, St. Louis, 1874; a member of the American Medical Association; formerly local surgeon of the Burlington System, and president of the Cottage Hospital, Creston, Ia.; superintendent of the Omaha General Hospital in 1905 and 1906; for the last two years a resident of Detroit; died in Harper Hospital, March 2, from nephritis following prostatectomy, aged 66.

Skiles McKechan Woodburn, M.D. University of Pennsylvania, Philadelphia, 1872; a member of the American Medical Association; and for many years inspector of the State Board of Health for Bradford County; for nine years local pension examiner; a member of the board of health, town council and board of education of Towanda, Pa.; died at his home, February 22, from pneumonia, aged 60.

John Williams Coe, M.D. Johns Hopkins Medical School, Baltimore, 1898; a member of the American Medical Association; and New York Academy of Medicine; instructor in clinical pathology in Cornell University Medical College; and physician to the skin department of the Presbyterian Hospital, New York City; died at that institution, March 6, from pneumonia, aged 38.

Daniel Maynard Burgess, M.D. New York University, New York City, 1852; a member of the American Medical Association; surgeon of the steamship *Atlantic* in 1856; health inspector for the United States government in Cuba from 1874 to 1898; an authority on yellow fever; died at his home in New York City, March 1, from pneumonia, aged 82.

Oswald Warner, M.D. College of Physicians and Surgeons, New York City, 1854; a veteran of the Civil War; formerly assistant on the medical staff of the New Jersey State Hospital, Morris Plains; for several terms president of the District Medical Society of Passaic, N. J.; died in Newark, February 20, aged 77.

Theodore Bacmeister, M.D. Homeopathic Medical College of Pennsylvania, Philadelphia, 1856; a pioneer practitioner of central Illinois; professor of materia medica and therapeutics in Hahnemann Medical College, Chicago, in 1869 and 1870; died suddenly at his home in Toulon, Ill., March 8, from angina pectoris, aged 81.

William Wheeler Hewlett, M.D. Bellevue Hospital Medical College, 1869; a member of the Medical Society of the State of New York; formerly president of the Suffolk County Medical Society; twice president of Babylon village and twice health officer; died at his home, March 5, from heart disease, aged 63.

George Duffield Stewart, M.D. Detroit (Mich.) Medical College, 1878; sheriff of Wayne County, Mich., in 1898 and 1899; formerly city physician of Detroit and physician of Wayne County; afterward a resident of Mt. Clemens; died at his home in that place, March 7, from nephritis, aged 55.

Girard Bryce Edwards, M.D. Ohio Medical University, Columbus, 1905; a veteran of the Spanish-American War; of Cheraw, Colo.; formerly of Clearfield, Pa.; and jail physician of Clearfield County; died at his home, March 1, from tetanus following an injury to the left ankle, aged 35.

Lowrie Payne Hapgood, M.D. Western Pennsylvania Medical College, Pittsburg, 1897; a member of the American Medical Association; formerly president of the school board of Bedford; died at his home in South Side, Pittsburg, March 6, from pneumonia, aged 34.

John T. Wilkins, M.D. Jefferson Medical College, 1843; University of Maryland, Baltimore, 1851; a member of the Northampton County (Va.) Medical Society; died at his home in Vaucluse near Eastville, Va., Nov. 16, 1910, from senile debility, aged 90.

Leonidas E. Best (license, Ontario, 1865); formerly of Grand Rapids, Mich.; for two terms coroner, and a member of the board of supervisors of Kent County; died at the home of his daughter in Salt Lake City, February 28, from cerebral hemorrhage, aged 66.

John S. Boyd, M.D. University of Pennsylvania, Philadelphia, 1870; superintendent of admission of Girard College, Philadelphia; and connected with the Girard estate for twenty-seven years; died at his home, March 6, from pneumonia, aged 62.

William T. Carpenter, M.D. University of Nashville, Tenn., 1864; of Iron Mountain; a veteran of the Civil War, and one of the founders of the Ishpeming Hospital; a member of the Michigan State Medical Society; died in Maitland, Fla., March 6, aged 73.

William A. Whitlock, M.D. University of Tennessee, Nashville, 1885; of Ukiah, Cal.; died in St. Winifred's Hospital, San Francisco, February 26, from brain disease following an infection received during an operation four months before, aged 58.

George Delos Coe, M.D. Eclectic Medical Institute, Cincinnati, 1872; a veteran of the Civil War; for several years city physician of Carthage, Mo.; died at his home in San Francisco, February 5, from acute intestinal disease, aged 73.

Alfred Lewis Wolfe, M.D. Washington University, Baltimore, 1877; a member of the American Medical Association; for several years a practitioner of Elkton, Va.; died at his home in Roanoke, Va., March 2, from tuberculosis, aged 57.

Thomas R. Mask, M.D. Leonard School of Medicine, Raleigh, N. C., 1889; an esteemed colored practitioner of Wilmington, N. C.; and a member of the New Hanover County Medical Society; died at his home, February 19, aged 48.

James Mooney, M.D. Detroit (Mich.) Medical College, 1877; a member of the American Medical Association, and Panhandle Medical Association; died at his home in Wellington, Tex., Dec. 4, 1910, from pneumonia, aged 58.

James B. Judson, M.D. Homeopathic Hospital College, Cleveland, O., 1876; a veteran of the Civil War, and a practitioner since 1863; died at his home in Springport, Mich., January 21, from cerebral hemorrhage, aged 66.

J. A. Parsons, M.D. Atlanta (Ga.) Medical College, 1884; of Bowersville; a member of the Medical Association of Georgia; died in the Grady Hospital, Atlanta, February 25, from cerebral hemorrhage, aged 49.

Elijah B. Woolston, M.D. University of Pennsylvania, Philadelphia, 1854; a member of the Medical Society of New Jersey; died at his home in Marlton, Dec. 17, 1910, from cerebral hemorrhage, aged 77.

Colin Bancroft McKenzie, M.D. University of Michigan, Ann Arbor, 1891; acting assistant surgeon U. S. P. H. and M.-H. Service; died at his home in Harbor Beach, Mich., March 6, from heart disease, aged 50.

M. Duke Kimbrough, M.D. University of Pennsylvania, Philadelphia, 1860; a member of the Medical Society of the State of North Carolina; died at his home in Mocksville, Nov. 26, 1910, aged 72.

Robert W. Joyner (license, North Carolina); a member of the American Medical Association and Seaboard Medical Association; died at his home in Woodland, January 11, from myocarditis, aged 70.

Frederick Howard Files, M.D. Medical School of Maine, Brunswick, 1888; a member of the South Dakota State Medical Association; died at his home in Madison, March 1, from pneumonia, aged 48.

King Holt, M.D. Tulane University, New Orleans, 1871; of Baton Rouge, La.; for several years a sanitary officer of the United States government in South America; died at his home, February 18.

Lewis Nathaniel Howard, M.D. Homeopathic Medical College of Missouri, St. Louis, 1870; a Confederate veteran; died at his home in Indianapolis, February 23, from interstitial nephritis, aged 73.

Charles Austin Jennings, M.D. Starling Medical College, Columbus, O., 1889; formerly of Delevan, Ill.; died at the home of his aunt near Olathe, Kan., February 21, from tuberculosis, aged 43.

John P. Johnston, M.D. Jefferson Medical College, 1879; a member of the West Virginia State Medical Association; died at his home in Wellsburg, March 6, from ptomain poisoning, aged 55.

Edmund Roy Gustin, M.D. University of Buffalo, N. Y., 1893; of Harrison Valley, Pa.; coroner of Potter County in 1895; died in the Williamsport General Hospital, February 9, aged 30.

Augustine Gandier, M.D. Queen's University, Kingston, Ont., 1890, and gold medalist of his year; M.R.C.S., L.R.C.P., L.S.A., London; died at his home in Sherbrooke, Que., Dec. 15, 1910, aged 45.

Charles Lisle Bond, M.D. University of Buffalo, N. Y., 1903; a member of the Medical Society of the State of New York; died at his home in Valois, February 25, from pneumonia, aged 38.

Frank J. Maschek, M.D. Rush Medical College, 1882; formerly a member of the American Medical Association; died at his home in Chicago, February 10, from cancer of the tongue, aged 50.

Lonnie Ray Wood, M.D. Vanderbilt University, Nashville, Tenn., 1910, and recipient of the Founder's Medal; died at his home in Attalla, Ala., February 9, from pneumonia, aged 23.

Oscar W. Roberts (license, Arkansas, 1907); an eclectic practitioner of Reyno; is said to have been killed by a blow from the mace of the city marshal of Reyno, Dec. 5, 1910, aged 26.

William B. Hart, M.D. University of Buffalo, N. Y., about 1846; for nearly sixty years a practitioner of McHenry County, Ill.; died at his home in Greenwood, February 19, aged 99.

Washington Jackson Caldwell (license, Tuscaloosa County, Ala.); a Confederate veteran and one of the oldest practitioners of Tuscaloosa; died at his home, February 28, aged 81.

Addison Wilson Bare, M.D. University of Louisville, Ky., 1860; a member of the Indiana State Medical Association; died at his home in Bryantsville, February 27, aged 84.

Merrill James Galloway, M.D. Philadelphia University of Medicine and Surgery, 1874; died at his home in Philadelphia, February 28, from heart disease, aged 72.

Isaac M. McBride, M.D. College of Physicians and Surgeons, Keokuk, Ia., 1877; died at his home in Rugby, N. Dak., March 1, from tuberculosis of the lungs, aged 56.

Maria Stewart Loughborogh Edwards, M.D. American Medical Missionary College, Chicago, 1899; formerly of Moline, Ill.; died in St. Helena, Cal., February 28.

Thomas A. Andrews, M.D. Jefferson Medical College, 1868; a Confederate veteran; died at his home in Seagoville, Tex., January 26, from pneumonia, aged 64.

George E. Williams, M.D. Medical College of Virginia, Richmond, 1902; formerly of Richmond; died at his home in Pearisburg, Va., February 21, aged 35.

Francis Marion Moore, M.D. Rush Medical College, 1876; Kansas City (Mo.) Medical College, 1879; died at his home near Perry, Mo., February 17, aged 55.

Edmon C. Waltersdorf, M.D. Hahnemann Medical College, Chicago, 1881; died at his home in Detroit, March 5, from accidental gas asphyxiation, aged 58.

L. B. Chilton, M.D. Shelby Medical College, Nashville, Tenn., about 1860; died at the home of his niece in Guthrie, Ky., January 5, from nephritis, aged 72.

Valentine Fritts, M.D. Kansas City (Mo.) Hospital College of Medicine, 1885; died at his home in Luray, Kan., February 5, from pneumonia, aged 61.

William C. Moughon, M.D. University of Louisville, Ky., 1876; died at his home in Wills Point, Tex., March 2, from laryngeal tuberculosis, aged 56.

John Biggs Standlee, M.D. American Medical College, Eclectic, St. Louis, 1904; died at his home in Peoria, Ill., February 17, from tuberculosis, aged 33.

Herschel Josephus Logan, M.D. University of the South, Sewanee, Tenn., 1897; died at his home near Plains, Ga., February 26, aged about 40.

George Davis (license, Iowa, years of practice, 1886); of Canton, Ia.; died at the home of his brother in South Garry Owen, February 9, aged 58.

Thomas Blackwood, M.D. Jefferson Medical College, 1874; died suddenly at his home in Flushing, O., February 20, from heart disease, aged 62.

John B. Hollingsworth, M.D. Starling Medical College, Columbus, O., 1865; died at his home in Quaker City, O., January 16, aged 78.

Eugene Orville Bardwell, M.D. University of Buffalo, N. Y., 1879; died at his home in Emporium, Pa., Jan. 4, 1910, from pneumonia, aged 55.

Francis J. J. McHugh, M.D. Detroit (Mich.) College of Medicine, 1889; died at his home in Detroit, February 25, from pneumonia, aged 50.

John E. Sommers, M.D. Eclectic Medical Institute, Cincinnati, 1892; died at his home in North Baltimore, O., February 26, aged 56.

Thomas Crosgrove, M.D. Rush Medical College, 1869; died at his home in Hubbard, Ia., February 18, from cancer of the face, aged 69.

N. L. Holt (license, Texas, 1907); died at his home in Chillicothe, February 22, four days after an operation for appendicitis, aged 36.

Lewis Addison Fairchild, M.D. Rush Medical College, 1890; died at his home in Peru, Neb., February 22, from diabetes, aged 62.

Charles J. Sherer (license, Oklahoma, Act of 1908); died suddenly at his home in Kent, Oct. 21, 1910, from heart disease.

C. Almon Paul, M.D. Hahnemann Medical College, Chicago, 1889; died at his home in Solon, Me., February 22, aged 57.

Thomas E. Tribble, M.D. University of Tennessee, Nashville, 1833; died at his home in Bloomfield, Mo., February 23.

"The Propaganda for Reform"

In This Department Appear Reports of the Council on Pharmacy and Chemistry and of the Association Laboratory, Together with Other Matter Tending to Aid Intelligent Prescribing and to Oppose Medical Fraud on the Public and on the Profession.

COMPRESSED OXYGEN

Report of the Council on Pharmacy and Chemistry

The referee of the Council appointed to report on the composition of compressed oxygen as found on the market and to make recommendations as to its inclusion with New and Nonofficial Remedies submitted the following report:

The Section on Stomatology at the 1909 session of the American Medical Association having recommended the inclusion of compressed oxygen with the U. S. Pharmacopeia, the Council voted to describe this product with New and Nonofficial Remedies until such Pharmacopeial recognition had been secured. This action having been decided on, it became necessary to provide standards of purity for this substance. Correspondence both with firms who make the product as well as with those who use it gave the referee of the Council little information as to what degree of purity should be required for this substance, and it therefore became necessary to examine the product as it was found on the market.

Professor Warren R. Smith of Lewis Institute, Chicago, kindly offered to cooperate with the Council and to make an examination of this product. The referee herewith transmits the very thorough report regarding the composition of commercial compressed oxygen which has been made by Professor Smith in collaboration with Edwin D. Leman. The referee recommends that the Council express its appreciation for the work and that it request publication of the report in The Journal. The referee further recommends that the description of compressed oxygen submitted herewith be adopted for inclusion with New and Nonofficial Remedies.

This report was adopted by the Council and in accordance therewith the examination of Smith and Leman is published below and the description of compressed oxygen appears with New and Nonofficial Remedies on another page of this issue of The Journal.

W. A. Puckner, Secretary.

The Purity of Compressed Oxygen

Prof. Warren R. Smith and Edwin D. Leman

We have recently examined three specimens of commercial oxygen, purchased in the open market, with the results shown in the accompanying table.

Maker	Chicago Oxygen Gas Co., Chicago	Ohio Chemical and Mfg. Co., Cleveland	S. S. White Dental Mfg. Co., Philadelphia
Per cent. oxygen	94.78 94.80* 94.78 94.80†	97.84 97.85* 97.84 97.86†	96.84 96.76* 96.84 96.93†

Carbon monoxid methane, etc.	Negative.	Negative.	Negative.

[1] That is, not absorbed by potassium pyrogallate.
* Smith.
† Leman.

The gas from the Chicago Oxygen Co. was claimed to be under a pressure of 16 atmospheres. The amount of nitrogen found in this sample is just about that which would be present if pure oxygen were forced into a container filled with air under one atmosphere pressure until a pressure of 16 atmospheres was reached. The other samples were stated to be under a pressure of 1,600 lbs., so that the amounts of nitrogen found cannot be accounted for by a similar hypothesis.

The potassium-iodid test mentioned in the table consisted in passing from 2 to 4 liters of the gas through a solution containing starch and potassium iodid. A negative result in this test shows that the gas is free from chlorin, ozone, oxids of nitrogen, etc. The negative results for carbon dioxid mean that not more than a slight opalescence was obtained by passing 2 to 4 liters of the gas through a solution of barium hydroxid. The carbon monoxid test was made by passing the gas through alkali to remove all carbon dioxid, then over heated platinum, and finally through barium hydroxid solution. A negative result here shows freedom from carbon monoxid, methane and other hydrocarbons.

Shot-Gun Prescriptions and Shot-Gun Specialties Combined

A physician in a small town in Nebraska writes: "In looking over a prescription file not long ago I found a prescription which I copied and am sending to you. It is a good example of shot-gun prescribing. I do not give the name of the prescriber, and you will please not mention from whence this comes. The doctor who wrote this has had about ten years' experience."

Here is the prescription given exactly as transmitted by our correspondent:

Sp. sticta	Gtt xv
Sp. ipecac	Gtt x
Sp. bryonia	Gtt x
Sp. macrotys	ʒi
Bromoform Bronchial Anodyne	℥ii
Syrup Cocillana Comp. q. s. ad	℥vi

Teaspoonful every two or three hours.

It is evident that the prescriber is an eclectic. As a matter of fact, in a second letter from the physician who forwarded the prescription, we are informed that the prescriber is a graduate of an eclectic institution not a thousand miles from where he practices. The "Sp" in the prescription does not mean "Spiritus," but specific tincture. The prescriber is an advocate of specific remedies, one of which should fit the condition, but he is broad-minded enough to call help from the outside, and so adds fifteen other remedies to the specific selected, including alcohol. The inability of one mind to remember all the ingredients of so complex a mixture will explain the fact that ipecac is duplicated, occurring both as a specific tincture and as an ingredient of Bromoform Bronchial Anodyne. The latter, the manufacturers tell us, contains in one fluidounce:

Alcohol	5 per cent.
Bromoform	8 drops
Ipecac	½ gr.
Ammonium bromid	24 grs.
Benzoin	1 gr.

Syrup Cocillana Comp., one of the "elegant specialties" of Parke, Davis & Co., of which they certainly ought to be very proud, contains, we are told, in one fluidounce:

Alcohol	5 per cent.
Heroin hydrochlorid	8/24 gr.
Tinct. of euphorbia pilulifera	120 min.
Syrup of wild lettuce	120 min.
Tinct. of cocillana	40 min.
Syrup of squill comp	24 min.
Cascarin, P. D. & Co	8 grs.
Menthol	8/100 gr.

This "elegant specialty" of Parke, Davis & Co. is not only a shot-gun prescription, but has as one of its ingredients a mixture itself containing three ingredients, namely: Syrup Squill Comp. (Coxe's Hive Syrup), making ten in all—a beautiful example of scientific pharmacy.

We wonder if our eclectic brother really appreciated that his prescription, written out, would be as follows:

Sp. sticta	Gtt xv
Sp. ipecac	Gtt x
Sp. bryonia	Gtt x
Sp. *macrotys*	ʒi
Alcohol	5 per cent.
Bromoform	8 drops
Ipecac	½ gr.
Ammonium bromid	24 grs
Benzoin	1 gr.
Alcohol	5 per cent.
Heroin hydrochlorid	8/24 gr.
Tinct. of euphorbia pilulifera	120 min.
Syrup of wild lettuce	120 min.
Tinct. of cocillana	40 min.
Fluidextract of squill	60 min.
Fluidextract of senega	60 min.
Antimony and potassium tartrate	1 gr.
Cascarin, P. D. & Co	8 grs.
Menthol	8/100 gr.

To use a slang expression, this is certainly going some!

Correspondence

Certified Butter in California

To the Editor:—Certification of butter in California was developed as an outgrowth of a series of experiments carried on in the laboratory of applied hygiene of the University of California by Mr. James M. Stephenson and myself. These experiments were undertaken to determine the need for municipal control of the butter supply of the city of Berkeley, and developed the presence of tuberculosis in much of the high-grade butter tested.

A review of the federal literature on the vitality of typhoid and tuberculosis bacilli in butter showed that previous experiments had been carried on with sweet cream butter. We therefore carefully followed the commercial process of souring and churning previously pasteurized cream. The cream samples were inoculated at the time of churning with pathogenic organisms, and the resulting butter was examined directly, plated and inoculated *into guinea-pigs intraperitoneally.*

Our results in brief were as follows:

Typhoid bacilli were recovered during the fourth week from endo-plates inoculated from broth subcultures of butter samples.

Diphtheria bacilli were recognized in smears made from blood-serum tubes inoculated with butter samples 26 days old, and guinea-pigs showed characteristic lesions at autopsy when inoculated from subcultures on blood-serum of butter 8 days old.

Generalized tuberculosis developed in guinea-pigs inoculated with butter 2 weeks old which had been contaminated at the time of churning by a small quantity of feces from a cow with tuberculosis.

In addition, generalized tuberculosis developed in guinea-pigs inoculated with three out of five high-grade butters obtained in open market. One of these had been intended as a control, as the butter was supposed to be made from pasteurized cream; but investigation revealed that not all of the cream coming to the butter factory was pasteurized.

Having been satisfied as to the need for pasteurized cream butter, the next step was the development of municipal butter control. For this purpose a score card for butter factories was devised on the basis of the federal score card for city milk plants, and a score card for butter which was in effect an extension of the present federal butter card. One of these cards gave due credit for pasteurization apparatus and its use, and the other gave ten points for a butter which would be Storch-test positive, showing that the cream had been heated to 80 C. It was also planned that butter factories where pasteurization was practiced might designate their product "inspected butter," under the supervision of the Berkeley Board of Health.

These points were incorporated in an ordinance governing the sale of milk products which was then submitted to the *Board of Health*, and by it recommended to the city council for passage.

A bill was also prepared and submitted to the California legislature, giving county medical milk commissions the authority to certify butter as free from pathogenic organisms, if the butter in question complied with regulations of the commission. The bill further penalized the use of the term "certified butter" without the authority of a medical milk commission. This bill has passed both houses of the present legislature, and the Milk Commission of the Alameda County Medical Association has agreed to adopt regulations for certified butter based on the pasteurization requirements as found in the milk-products ordinance of Berkeley.

The plan is not extreme, nor does it work a hardship on the producer. All butter in Denmark must be made from pasteurized cream, and it seems inconceivable that we have hitherto bent all our energies toward certified milk production and allowed this menace to our later years to persist without legislative correction. JOHN NIVISON FORCE, M.D., M.S.,

Lecturer in Hygiene, Univ. of California, Berkeley, Cal.

The Philadelphia Idea as to Medical Teaching

To the Editor:—In The Journal, February 25, p. 608, under the above heading, there is the following extraordinary statement, by Prof. H. A. Hare, of Philadelphia: "As a matter of historical fact, Jefferson Medical College was the first medical institution in America to establish clinical teaching."

Now, "clinical teaching" is as old in this country as medical colleges; for, at the very beginning of the Philadelphia Medical College (University of Pennsylvania), we find that such instruction was given the students in the Pennsylvania Hospital. The first medical diploma, that of John Archer, of Maryland, (1768), is signed by "Thomas Bond, Collegii & Academ. Curator et Praelec. Clinicus" (clinical lecturer), with the following endorsement: "Fidem facio Virum ornatum Joannem Archer Praelectionibus Clinici et Praxi in Nosocomio Philadelphiense interfuisse et Fructus Diligentiæ suae uberrime consecutum fuisse."

The younger Wiesenthal, of Baltimore, describes these clinics in letters to his father, while a medical student in Philadelphia, and the elder Wiesenthal (a most competent judge) speaks highly of Bond's qualifications for the task. The medical histories, as Mumford and Packard, show that these Philadelphia clinics were "rich and abundant."

Nor were the Boston, New York and Baltimore schools without their clinics. The New York Hospital was available from 1807 on, and the Massachusetts General Hospital was opened in 1821. In Baltimore, during the period from 1807 to 1823, clinical lectures were given by Davidge, Potter, William Gibson, Pattison, George Frick, the oculist (and author of the first American work on the eye) and others, at the Maryland Hospital, on Broadway, at the City Almshouse Hospital, on Harvard Street, and at Dr. Gibson's private hospital.

"As a matter of historical fact," however, the first medical school in the country to have its own hospital was the Department of Medicine of the University of Maryland. This was opened Sept. 20, 1823, in a building, especially erected for the purpose, just across the street from the medical college. It had at first four wards, one being for the eye.

Jefferson Medical College was founded in 1824, but the course of lectures did not begin until 1825. I have seen somewhere a statement by the late Prof. Samuel D. Gross, similar to that of Professor Hare, that Jefferson Medical College was the first in this country to establish a college hospital, which it did in 1825.

Eugene F. Cordell, M.D., Baltimore.
Professor of the History of Medicine, Univ. of Maryland.

Incomes of Physicians

To the Editor:—I enclose a newspaper article purporting to be an abstract of the address of Dr. H. W. Wiley of the Department of Agriculture. I have marked a paragraph in which he is quoted as saying: "There are 120,000 physicians in this country—120,000 men living on princely salaries because we ignore the possibility of our losing our health."

This article has been published broadcast and will give the public another wrong impression of our profession. People already think that physicians charge too much and this only adds to the false ideas as to the income of a medical man. Dr. Wiley knows that the average income of physicians in the United States is less than $1,000 a year. A princely salary, indeed! The physicians of this country are having a hard enough time to get along without such statements being made—false statements at that. The American Medical Association should take some action to contradict such statements.

F. E. Wallace, M.D., Pueblo, Colo.

[This letter was referred to Dr. Wiley, who replies as follows:]

To the Editor:—The remarks attributed to me in the address before the Republican Club were evidently made by one of the other speakers. I have forgotten which speaker it was who gave statistical data as to the number of sick people and the cost of their medical attendance, but it was not I. I said nothing at all about the matter. I did, however, say in an address before Columbia University on the evening of the same day that young men might just as well give up the idea that there was any learned profession which gave promise of princely salaries and I stated that in my opinion the average salary of the physicians of the United States was less than $1,000 a year, which is about the same as the estimate given by Dr. Wallace. I suppose that there are twenty-five or perhaps a hundred in this country who do earn "princely" salaries, but it never entered my mind that such earnings were common to the profession.

H. W. Wiley, Washington, D. C.

Plague in China

To the Editor:—I expected to take my furlough in the early spring . . . My plans have recently been changed owing to the arrival of the plague in this vicinity, making it necessary for me to remain at my post. . . .

I have been in the vicinity of plague before, but it was not like that which is surrounding us at the present time, viz., pneumonic and septicemic. The pneumonic is by far the most common. It seems to me to be reasonable to ascribe the presence of these two varieties to the intense cold and to the conditions under which the people live. The temperature is often 30 below zero and the Chinese huddle together on large brick beds, as they go up to Manchuria from the northern provinces of China to do coolie work. Under these conditions, if bubonic plague got under way it would not be strange if its virulence should increase and take on the more severe forms. The septicemic type seems to be less contagious, or the contagion does not emanate from the patient in a continuous stream as it does from the pneumonic variety. The matter vomited in the latter type contains the bacilli.

J. H. Ingram, Tungchou, Peking, China.

[Comment:—The above is taken from a letter of a subscriber who is writing on other matters. What is said regarding the plague is incidental. This is an example of one man sticking to his post in time of danger.—Editor.]

Queries and Minor Notes

Anonymous Communications will not be noticed. Every letter must contain the writer's name and address, but these will be omitted, on request.

EFECTS OF THIOSINAMIN

To the Editor:—I would like information from the profession at large in regard to the effects of thiosinamin. In a case of polymyositis I have been giving hypodermic injections of this drug. The patient has been affected with this trouble for more than a year and the muscles are in a stage of fibrous degeneration. The drug has been administered with the view of obtaining its reputed effect of causing an absorption of cicatricial tissues.

The patient has received two injections weekly for the past seven weeks with but little beneficial effect. After the last five injections, however, there has been a uniform marked reaction, as follows: About two hours after the injection of 3 grains of the drug a severe chill occurs, followed by a rise of temperature to about 102 F. This temperature persists for from twenty-four to thirty-six hours. After the first two days it is accompanied by profuse perspiration and marked heart weakness. During the second day improvement begins. By the third day the patient is in her usual condition.

I would like to know if any other physician has ever used this drug with benefit, and if they have seen any such reaction.

I am unable to find any literature relating to this effect.

Charles F. Clowe, M.D., Schenectady, N. Y.

Answer.—There are numerous reports in the literature in which beneficial results from the use of thiosinamin and the solution of thiosinamin and sodium salicylate are said to have been obtained. There is considerable doubt as to its permanent value in removing or softening scar tissue.

Thiosinamin poisoning has been reported in the last few years by a number of authors. Fever produced by this agent was noted by Hebra, who introduced the drug into medicine. His patient was tuberculous but free from fever. After the injections fever occurred, but it was uncertain whether it was due to the thiosinamin or to the tuberculosis.

Kunkel (Manual of Toxicology, 1901) reports headache, nausea, vomiting and lassitude after large doses (1 gm.) in man.

Brinitzer observed repeatedly attacks of fever up to 39.8 C. (103.6 F.) in a patient whom he was treating for scleroderma.

P. Grosse (*München. med. Wchnschr.*, April 28, 1908, p. 910) reports a case in which slight symptoms appeared after the first five injections, but the sixth was followed by a rise of temperature to 39.1 C. (102.4 F.), with weak pulse, loss of appetite, etc. A striking feature repeated in other cases was a loss of memory of the period in which the symptoms appeared.

Baumstark observed similar symptoms in a patient whom he was treating for cholecystitis.

F. Hayn (*München. med. Wchnschr.*, Feb. 15, 1910) reports a case in which the ordinary dose, 0.2 gm. (3 grains), produced chills and fever, severe headache, thirst and marked weakness. Severe vomiting occurred with the first symptoms of poisoning. In this case the symptoms began with the fifth dose.

R. Neisse (*Therap. Monatsh.*, May, 1910) reports a case of fever occurring after injection of solution of thiosinamin sodium salicylate in a patient in whom there was suspicion of tuberculosis, and recommends that caution be used in treating tuberculous individuals with thiosinamin.

Kölliker reports (*München. med. Wchnschr.*, July 19, 1910, p. 1550) a case of thiosinamin poisoning in a young woman to whom it was being administered for the relief of keloid. The first symptoms appeared after the fifth injection and consisted of chilliness, sweating, general malaise and severe headache. These symptoms appeared after every injection but were variable in duration. The headache lasted for from two to eight days and was entirely independent of the interval between the two injections. After an interval of nineteen days the symptoms of poisoning appeared with the same intensity as after an interval of one day. The injections, however, were continued and the treatment was successful. No influence on menstruation was observed.

HEMOPHILIA

To the Editor:—Two children, aged respectively 6 and 8 years, have been under my care since birth. On their mother's side they belong to a family of bleeders. They have severe attacks of epistaxis and also have frequent attacks of acute articular rheumatism; both have valvular disease. I have given suprarenal preparations and also the elixir of chlorid of calcium; both seem to do good, but for a short time only. Can you recommend anything better?

N. C. Miller, Stroudsburg, Pa.

Answer.—Good results have followed the use of normal blood-serum (rabbit, horse or man), locally, subcutaneously and intravenously. A serum injection of from 20 to 30 c.c., subcutaneously, usually suffices, although it may be necessary to repeat the injection daily or every two or three days if indicated. The ordinary antidiphtheritic serum has been used. It does not need to be fresh; Hare has used serum that had been kept for six months. It is possible that the attacks of "acute articular rheumatism" are in reality "bleeder joints," the pain being due to small hemorrhages into the joint and subsiding with absorption of the blood.

HICCUP NOT ATTRIBUTED TO BACILLI

To the Editor:—Please inform me if a bacillus causes hiccup (singultus). If so, has it been isolated, and by whom? I have a case of hiccup of three years' standing. Can you furnisa any literature on the subject or inform me where I can obtain any data?

F. H. Longley, M.D., North Platte, Neb.

Answer.—A bacillus of hiccup—singultus—has not been isolated and it is hardly expected that one will be found, since hiccup is merely a symptom. The condition is discussed in the various textbooks on medicine and therapeutics; there is practically no current literature in regard to it. We have reference to one article during the last five years:

Bassler, A.: Singultus Gastricus Nervosus, *New York Med. Jour.*, Aug. 13, 1910; abstr. in The Journal A. M. A., Aug. 27, 1910, p. 800.

Complications of Typhus Fever.—E. Legrain and R. Treille review their experiences in northern Africa and assert that disinfection of the sick-room and sterilization of the mouths of patients with exanthematous typhus have always proved effectual in warding off complications in their experience. In epidemics in which these measures were neglected, complications were frequent and severe. In their communication on the subject in *Afrique Médicale*, 1910, xi, 377, they report some typical cases of severe complications, parotitis, joint affections and psoitis in the course of convalescence. Other patients presented symptoms suggesting secondary pancreatitis, suppurative meningitis, or abscesses in the mouth and neck. They cite a description of typhus A. D. 1300, and others by Italian writers in the fifteenth and sixteenth centuries.

The Public Service

Medical Department, U. S. Army

Changes for the week ended March 11, 1911.

Stallman, George E., D.S., March 2, reported for temporary duty at Fort Clark, Texas.

Dougherty, James C., M.R.C., February 9, reports in field for duty along Mexican boundary.

Daywalt, George W., M.R.C., March 6, ordered to proceed to his home, and on arrival there will report to the adjutant general of the Army for further orders.

Allen, John H., major, March 8, left Fort Myer, Va., with 3d Field Artillery en route to San Antonio, Texas, for field duty.

Wickline, William A., captain; Schlanser, A. E., and Bastion, J. E., lieuts., March 9, left Walter Reed General Hospital, Takoma Park, D. C., with Co. C, Hospital Corps, en route to San Antonio, Texas, for field duty.

Bartlett, William K., captain, March 7, appointed member of commission to meet at Washington, D. C., relating to the establishment of maneuvering ground and camp of inspection, rifle and artillery ranges near Chickamauga Park, Ga.

Krebs, Lloyd Le R., captain, March 7, honorably discharged from the service of the U. S.

Birmingham, H. P., lieut.-col., March 7, assigned to duty as chief surgeon of division now being concentrated at San Antonio Park.

Persons, Elbert E., major, March 7, ordered to San Antonio, Texas, for duty in chief surgeon's office, division at that place.

Whitcomber, C. C., captain, March 7, ordered to San Antonio; Texas, for duty as medical supply officer.

Roberts, William M., major, March 7, relieved from temporary duty at Fort Oglethorpe, Ga., and ordered to proceed with the 11th Cavalry to Fort Sam Houston, Texas.

Straub, Paul F., major, March 7, ordered to proceed to San Antonio, Texas, for duty as sanitary inspector of division.

Truby, Willard F., major, March 7, ordered to proceed to San Diego, Cal., and report for duty as commanding officer of the field hospital at that place.

Dutcher, Basil H.; Gilchrist, Harry L.; Hartsock, F. M., and Patterson, Robert U., majors, March 7, ordered to San Antonio. Texas, to assume command of the four field hospitals to be assembled at that place.

Jones, Percy L., captain, March 7, ordered to San Antonio, Texas, for duty in command of Ambulance Co. No. 2 at that place.

Baker, David, major, and Darby, Taylor E., lieut., March 7. left Fort McPherson, Ga., en route to Fort Sam Houston, Texas.

O'Connor, R. P., major, March 8, left Fort Screven, Ga., with troops en route to Galveston, Texas.

Bartlett, William K., captain, March 8, left Fort Oglethorpe, Ga., *en route to Fort Sam Houston, Texas.*

Hill, Eben C., lieut., March 8, left Madison Barracks, N. Y., en route to *Fort Monroe, Va., for temporary duty.*

Ford, Joseph H., major, March 8, left Fort Wadsworth, N. Y., with troops for duty in Texas.

Persons, Elbert E., major, March 8, left Fort Jay, N. Y., en route to San Antonio, Texas.

Fauntleroy, P. C., major, March 8, left Fort Benjamin Harrison, Ind., with the 10th Infantry en route to Fort Sam Houston, Texas.

Halliday, Charles H., M.R.C., March 9, left Fort Fremont, S. C., en route to Jackson Barracks, La., for temporary duty.

Waterhouse, S. M., major, March 9, left Fort Washington, Md., with troops en route to Fort Monroe, Va., and for duty in Texas.

Long, Charles J., D.S., March 9, left Fort Andrews, Mass., *en* route to Fort Constitution, N. H., for temporary duty.

Medical Corps, U. S. Navy

Changes during the week ended Feb. 18, 1911.

Cecil, A. B., asst.-surgeon, detached from the *Nebraska* and ordered to the naval station, Gauntanamo, Cuba.

Changes during the week ended March 11, 1911.

Olcott, F. W., P. A. surgeon, commissioned passed assistant surgeon from Feb. 13, 1911, and transferred to the retired list from that date.

Richardson, R. R., surgeon, detached from the navy yard, Portsmouth, N. H., and ordered to the *Prairie*.

Downey, J. O., P. A. surgeon, detached from the naval hospital, Philadelphia, and ordered to the *Prairie*.

Pugh, W. S., P. A. surgeon, detached from the naval hospital, New York, and ordered to the *Dixie*.

Elmore, B., A. A. surgeon, commissioned acting assistant surgeon from March 4, 1911.

Beyer, H. G., medical director, commissioned medical director from Feb. 27, 1911.

Mink, O. K., P. A. surgeon, detached from the naval medical school, Washington, D. C., and ordered to the *West Virginia*.

Miller, J. T., P. A. surgeon, detached from the Navy recruiting station, St. Louis, and ordered to the *Franklin*.

Abeken, F. G., P. A. surgeon, detached from the *West Virginia* and ordered to the Navy recruiting station, St. Louis.

Higgins, M. E., P. A. surgeon, ordered to the naval medical school, Washington, D. C.

U. S. Public Health and Marine-Hospital Service

Changes for the seven days ended March 8, 1911.

Cofer, L. E., assistant surgeon-general, granted ten days' leave of absence from March 6, 1911.

Pettyjohn, J., P. A. surgeon, granted one month's leave of absence from Feb. 23, 1911, on account of sickness.

Hamilton, H. J., A. A. surgeon, granted seven days' leave of absence from March 6, 1911.

Schug, F. J., A. A. surgeon, leave of absence for thirty days from Feb. 18, 1911, revoked.

Medical Economics

THIS DEPARTMENT EMBODIES THE SUBJECTS OF ORGANIZATION, POSTGRADUATE WORK, CONTRACT PRACTICE, INSURANCE FEES, LEGISLATION, ETC.

STATE LEGISLATION ON PUBLIC HEALTH

The progress of legislation and the new bills introduced regarding which THE JOURNAL has been informed, are reported below by states.

ALABAMA

A bill is introduced by Senator Justice to amend the existing medical practice act by giving the State Board of Medical Examiners power to revoke a physician's certificate for use of liquor or narcotic drugs to such an extent as to render him unsafe or unreliable as a practitioner; being so infirm mentally as to render him unsafe and unreliable; being guilty of gross immorality and unprofessional conduct likely to deceive, defraud or injure the public; advertising himself or his practice; inducing or aiding in inducing a criminal abortion; performing an operation of major surgery when his certificate does not entitle him to do so or being convicted of any offense involving moral turpitude. The bill also provides the manner of bringing charges and of procedure on the part of the board. This bill has passed the senate. An optometry bill has also been introduced.

CALIFORNIA

The senate has passed a bill making it a felony to trade in medical certificates or diplomas from medical colleges or to use the title of "doctor" or any other title having a similar meaning for fraudulent purposes. A bill has also passed the senate providing that an applicant for a license to practice medicine or other form of healing who passes the examination in seven of the ten required subjects shall be allowed a reexamination in the remaining three. A bill to repeal the compulsory vaccination law has passed the lower house. A bill to amend the present medical practice act has been defeated in the senate.

COLORADO

The following bills have been introduced: to regulate slaughter houses; a meat inspection bill; to create local boards of health; to provide for the medical inspection of school teachers and children for contagious diseases; to regulate the use of the common drinking cup; to prohibit the sale of undrawn cold storage poultry, fish or game; to amend the vital statistics law; to provide for the sanitary keeping, storing and transportation of foodstuffs; to repeal the compulsory vaccination law; to provide for the sanitation of bakeries, canneries, packing houses and all places where food is prepared, manufactured, packed, stored, sold or distributed; to provide for dental examination of children; to regulate the location of sanitariums for tuberculosis; to regulate the sale of habit-forming drugs; to provide for the supervision of lying-in hospitals and maternity homes; to regulate embalming; to establish a chiropractic board of examiners; to establish an optometry board of examiners and to amend the pure food law.

CONNECTICUT

An optometry bill has been introduced, also a bill to repeal the compulsory vaccination law. Several bills to amend the act of 1909 establishing country homes for the care of tuberculosis, have been introduced. One of the most unusual of state enactments is a bill passed by the Connecticut legislature giving Stephen Benoni Sweet, son of Dr. J. Byron Sweet, a member of the lower house of the legislature, the right to practice bone-setting and to call himself "doctor." According to newspaper reports, this act is due to the "wonderful gift that has been in the Sweet family since 1630." No statement appears in the press reports as to why this "wonderful gift" was not supplemented by a course of medical instruction.

ILLINOIS

The following bills have been introduced in the Illinois legislature: H. B. 29, to amend the employer's liability law; H. B. 94, to enable boards of education in cities to establish classes and schools for deaf, dumb, crippled children, blind, truant, subnormal, convalescent and incipient invalid children; H. B. 140, to establish a surgical institute for children; H. B. 146, to provide a pension fund for municipal employees; H. B. 152, to prevent fraud in the sale of dairy products, etc.; H. B. 153, to regulate the sale of concentrated food stuffs; H. B. 154, to regulate the manufacture, packing, storing and sale of food articles; H. B. 169, to make appropriations for the maintenance of the College of Medicine of the University of Illinois; H. B. 193, to regulate hotels, inns and lodging houses; H. B. 201, to regulate the practice of chiropody; H. B. 213, to authorize the improvement of streams; H. B. 214, to create a state board of forestry; H. B. 215, to create a state board of education; H. B. 241, to revise the divorce law by making the habitual use of morphin for two years grounds for divorce; H. B. 260, to protect employees of the state from the dangers of occupational diseases; H. B. 260, to regulate the work of children under 16 years of age; H. B. 380, to amend the medical practice act; S. B. 246, to amend the coroners' law; S. B. 249, to revise the law regarding the commitment and detention of lunatics; S. B. 260, to provide for the inspection, license and regulation of cold storage houses; S. B. 264, to amend the factory inspection law, and S. B. 459, to establish a state colony for epileptics.

INDIANA

The school medical inspection bill, drafted by the State Board of Education, to authorize school authorities to institute medical inspection of school children and to make such inspection compulsory after 1915, passed the senate. It further authorizes the State Board of Health and the State Board of Education to prepare leaflets on the prevention of disease and the conservation of health and to teach these subjects in all public schools. It also provides for sanitary sites and buildings for public schools and for proper heating, lighting and ventilation. A bill has been introduced to provide for the reporting of all defective children to the State Board of Health; also a weights and measure bill, to establish standards and to authorize the State Board of Health, through its food and drug inspectors, to enforce these standards. A bill to appropriate funds for a state hospital for tuberculosis and for the collection of vital statistics has been introduced. A bill has passed the house to require medical examination and certification of freedom from venereal diseases on the part of male applicants for marriage licenses. A bill to require a license fee of $10 a month for itinerant vendors has been introduced in the house; a child labor bill, a bill to prevent spitting in stores, public buildings and public places, and a bill to regulate the storing of food products in cold storage warehouses, have also been introduced. Governor Marshall has signed the cold storage label bill, the medical inspection bill and the ophthalmia neonatorum bill. A bill introduced by Senator Stotsenburg would provide for the issuance of medical licenses without examination until July 1, 1911. It is alleged that this bill was introduced for personal reasons, in order to obtain a license for a woman who has failed to pass the state board examination. The bill is opposed by the state board of medical examiners and the state society. Dr. W. T. Gott, secretary of the state board, states that there are about 600 persons in Indiana who have failed to pass the state board examination who would take advantage of this opportunity to register, as well as many others from the surrounding states who would flock in at once. Probably the bitterest fight in the legislature has been over the Gers bill, which was intended to deprive the secretary of the State Board of Health of most of his power. The bill was voted down by the senate, 41 to 7.

IOWA

A bill to change the composition of the State Board of Medical Examiners has passed the house. This bill provides that in addition to the superintendent of public instruction, the state board shall consist of one county superintendent, one member of the school board, one superintendent of city schools, one primary teacher and one teacher of a rural school. A bill to abolish the state board of veterinary examiners has been introduced. A bill to provide for the sterilization of criminals, idiots, feeble-minded and epileptics, modeled after the Indiana law, has been introduced.

KANSAS

A bill to appropriate $100,000 to build a clinical hospital in Kansas City, Kan., in connection with the Kansas University Medical School, has been introduced; also a bill to provide for the registration of births and deaths, drafted on the lines of the model bill of the American Medical Association. This bill has been favorably reported on by the house committee.

MAINE

The osteopathic bill has been defeated in the senate by a vote of 15 to 14 and in the house by a vote of 91 to 36. A bill to prohibit the issuance of insurance policies protecting physicians and surgeons against malpractice damages has also been defeated. A bill to amend the medical practice act has been introduced.

MASSACHUSETTS

A large number of bills of interest to the medical profession have been introduced, among them bills to prohibit the sale of intoxicating liquor and narcotic drugs to hospital patients; to regulate the cold storage of food products; to regulate the lighting of factories and work shops; to regulate meat inspection; to regulate the sale of cocain; to regulate the practice of healing by unregistered physicians; for the prevention of cruelty to animals; to regulate the distribution of milk; to prohibit spitting in public places; to require practitioners of Eddyism and hypnotism to register with the State Board of Health; to prohibit the use of suction shuttles in factories; to regulate the sanitary arrangements of factories, work shops, etc.; to regulate the sale of opium; to provide for the disinfection of public telephone stations; to regulate the cutting of ice, and to establish a board in optometry.

MICHIGAN

A "chiropractic" bill has been introduced.

MINNESOTA

A bill has passed the senate to create a state tuberculosis commission and to authorize the establishing of public tuberculosis sanatoriums in each congressional district. This bill has been prepared by the legislative committee of the Minnesota Association for the Prevention and Relief of Tuberculosis. An itinerant vendors' bill has been introduced and a bill to authorize the appointment of sixty-three state medical inspectors and sanitary inspectors.

MISSOURI

A bill to establish a board of examiners in optometry has been defeated in the senate. A bill to require all who profess to cure physical and mental ills to have diplomas from medical colleges has been introduced.

MONTANA

The Montana legislature has adjourned. The following bills have become laws: S. B. 134, providing that sewage systems must be approved by the State Board of Health and relating to the pollution of water supply; H. B. 27, regulating the sale of habit-forming drugs; H. B. 115, providing for the payment of physicians in insanity examinations; H. B. 290, prohibiting the possession or sale of toy pistols, blank cartridges and explosive caps; H. B. 34, the pure food law; H. B. 121, the dairy law, and H. B. 139, providing for state veterinary surgeons passed both houses and are now in the governor's hands; H. B. 364, to regulate the lighting, heating and ventilating of public buildings was not passed. The bill providing for a tuberculosis sanitarium passed both houses and has been signed by the governor; also a bill appropriating $5,000 for 1911 and an equal sum for 1912, to continue the investigation of spotted fever.

NEVADA

An osteopathic bill passed the house but failed to pass the senate. Bills to amend the medical practice act to create a state board of health have been introduced.

NEW HAMPSHIRE

Bills have been introduced to amend the medical practice act, to prevent the pollution of the Winnepesaukee River, to regulate weights and measures and to provide for the medical inspection of schools.

NEW JERSEY

An osteopathic bill, a bill to regulate cold storage and a bill to raise the standard of medical practice in the state have been introduced.

NORTH DAKOTA

A bill to regulate the management of hospitals has been introduced, containing a section providing that no major operation shall be performed on any patient in any licensed hospital, except in an emergency, until the attending surgeon has filed with the superintendent of the hospital a statement giving the reasons for the operation and the pathologic conditions which render it necessary. This statement must be approved and signed by an independent physician not in any way a financial beneficiary from the operation. An additional section provides that all diseased organs or tissues removed in the course of an operation must be sent to the state public health laboratory for examination.

OHIO

An optometry bill, similar to the one which Governor Harmon vetoed last year, has been introduced; also a bill for instruction of persons suffering from tuberculosis; a bill for the sterilization of criminals, imbeciles, epileptics and others; a bill to regulate the medical inspection of public school children; a bill to regulate the sale of articles of food held in cold storage; a bill to authorize boards of health to establish dispensaries; a bill to regulate the requirements for admission to any college of law, medicine, dentistry or pharmacy; a bill to provide for the proper certification of deaths in municipal hospitals; a bill to make vaccination optional and a bill separating inmates of the penitentiary and reformatory suffering from tuberculosis. A housing bill, endorsed by the associated charities of the state, as well as a sanitary bill, placing all members of the sanitary police force under civil service, and a bill to place infantile paralysis and ophthalmia neonatorum on the list of communicable diseases, have also been introduced.

OREGON

A bill has been introduced to recognize "Naturopathy."

PENNSYLVANIA

An optometry bill has been introduced, also a number of bills to regulate the practice of medicine. A bill to authorize the sterilization of idiots, feeble-minded and insane persons has been introduced; also a bill to regulate the sale of cocain; a bill to appropriate $425,000 for Jefferson Medical College and a bill to prevent the issuance of marriage licenses to imbeciles, epileptics or persons afflicted with a transmissible disease or under the influence of intoxicating liquors or narcotic drugs, have also been introduced.

RHODE ISLAND

The usual osteopathic bill has been introduced.

TENNESSEE

A vital statistics bill has been introduced; also a bill to create county boards of health; a bill to amend the pure food law and a bill to provide for medical inspection of schools.

TEXAS

An optometry bill has been introduced; also a bill to appropriate $150,000 for a tuberculosis sanitarium and a bill to incorporate the sanitary code of the health department as a law and to reenact the law creating the State Board of Health; a bill to exempt graduates of the Medical Department of the State University from examination by the state board has been reported on adversely by the house committee.

UTAH

A bill to empower the State Board of Health to revoke the licenses of physicians who fail to report contagious diseases and deaths; also a bill to regulate the sale of narcotic drugs, and a bill to provide for the examination of school children have been introduced.

WASHINGTON

A bill to provide for the appointment of a tuberculosis commission has been introduced; also a bill to amend the medical practice act. The State Board of Health is supporting a bill for the supervision and preservation of the water supplies for cities; also a bill to remove the health officers of the state from politics and to place them under the control of the State Board of Health.

WEST VIRGINIA

Governor Glascock has signed a bill to establish a state tuberculosis sanitarium, and a bill to regulate the sale of habit-forming drugs; a bill to establish medical inspection in public schools has become a law; a bill to amend the child labor law has passed the house; two bills to amend the medical practice act in an undesirable manner have died in the committee.

WISCONSIN

The following bills have been introduced: *for the prevention* and suppression of contagious diseases among live stock; to abolish the use of the common drinking cup on railway trains; for the prevention and control of dangerous communicable diseases; to regulate the hours of labor for women in manufacturing establishments; to provide for the registration of nurses; one relating to the organization of local boards of health; to regulate the pollution of streams and public waters; to regulate the sale of undressed poultry; to provide for the medical inspection of public school children; to forbid expectoration in public places; to make provision for the care of indigent, crippled and deformed children; to provide for the incorporation of medical milk commissions and the certification of milk.

POSTGRADUATE COURSE FOR COUNTY SOCIETIES

DR. JOHN H. BLACKBURN, DIRECTOR
Bowling Green, Kentucky

[The Director will be glad to furnish further information and literature to any county society desiring to take up the course.]

Eighth Month—Third Weekly Meeting

Diseases of the Ovaries

Oophoritic Cysts: Glandular and dermoid; pathology and description of each.

Paroophoritic Cysts: Pathology, description.

Complications of Ovarian Cysts: Inflammation, hemorrhage, twisting of pedicle, rupture and adhesions; symptoms and diagnosis of each.

Diagnosis of Ovarian Cysts: Pelvic stage: Position, mobility, relations, shape and consistency of tumor. Abdominal stage: Physical signs on inspection, palpation, percussion, mensuration, auscultation. Exploratory incision.

Differential Diagnosis: Differentiate from pregnancy, phantom tumor, encysted ascites, fibrocyst of uterus, cystic tumor of kidney.

Parovarian Cysts: Pathology: Size, characteristics, cyst wall, contents. Symptoms: Pressure symptoms, menstrual disorders, sterility.

Medical Education and State Boards of Registration

COMING EXAMINATIONS

Arizona: Phoenix, April 3-4. Sec., Dr. Ancil Martin.

California: San Francisco, April 4. Sec., Dr. Charles L. Tisdale, 929 Butler Bldg.

Colorado: Denver, April 4. Sec., Dr. S. D. Van Meter, 1723 Tremont Place.

District of Columbia: Washington, April 11. Sec., Dr. George C. Ober, 125 B St., S.-E.

Georgia Eclectic: State Capitol, Atlanta, about April 20. Sec., Dr. C. W. Miller, 192 W. North Ave.

Idaho: Boise, April 4-5. Sec., Dr. O. J. Allen, Bellevue.

Minnesota: State University, Minneapolis, April 4. Sec., Dr. W. S. Fullerton, 215 American National Bank Bldg., St. Paul.

Montana: The Capitol, Helena, April 4. Sec., Dr. William C. Riddell.

Oklahoma: Oklahoma City, April 11. Sec., Dr. Frank P. Davis, Enid.

Rhode Island: State House, Providence, April 6-7. Sec., Dr. Gardner T. Swarts, State House.

Utah: Salt Lake City, April 4-5. Sec., Dr. G. F. Harding, 310 Templeton Bldg.

West Virginia: Huntington, April 10-12. Sec., Dr. H. A. Barbee, Point Pleasant.

A Diploma Factory

In September, 1910, there came to this office several copies of a circular advertising the Gate City Medical College of Dallas, Tex. (formerly of Texarkana, Tex.). This circular was widely distributed through the southern states. It gave no street address for the college but contained the following specific directions as to how an applicant might reach the right parties:

> When you arrive in Dallas go to some hotel or business house and call us over the telephone. Our number is Main 3941 and Main 6631, or take the Hickory Street car and come to the Hickory Street drug store, corner Hickory and Nettie Streets, where you can get all desired information. Hickory cars pass in front of the postoffice, making it easy to find.

The suggestion was made to a Mississippi physician, who had sent us one of the circulars, that he endeavor to learn on what terms a diploma might be obtained, whereon he sent the following letter:

> ———, Miss., Oct. 8, 1910.
>
> Dr. J. W. Decker, Dean,
> Dallas, Texas:
>
> Dear Sir.—I am convinced of the great nead of a Diploma for a practitioner. I wish I could atend the Gate City Medical College but I have a very large practice No Doctor in 15 miles and sickness in my family. It is impossible for me to come. I would not mind the expense. Is it possible for me to pay like I was there and you give me the Diploma without Coming. I am a lisensed Doctor and can give best references.
>
> Your friend, ...

And here is the reply:

> Gate City Medical College
> J. W. Decker, M.D., Dean.
> Dallas, Texas. ———190
>
> Dear Doctor ———.
>
> In reply to yours of some days ago I will say that I can arrange to give you some home reading and give you a diploma same as if you were here. It will be genuine and will be entered upon the records same as if you were here, and you can refer to us as a graduate of the school at any future time should you wish to do so as many have done.
>
> Very truly yours,
> J. W. Decker, M. D., Dean.
>
> P. S. The whole fees will be only $50 professors fee. No extra charges for anything else and I will guarantee you to get your diploma D.
>
> If satisfactory send fee at once and I will send you some work to be looking over and enter your name for a diploma. Give me your full name.

In the meantime one of the circulars and copies of the above correspondence were sent to the former secretary of the Texas State Board of Medical Examiners, who referred the matter to the board's attorney, Mr. J. N. Wilkerson. The attorney reported that he personally called at Dr. Decker's office and that he succeeded, in about half an hour, in purchasing outright two diplomas for the stipulated sum of $50, without having ever taken any medical work and without having passed an examination. The so-called regular diploma, he said, was printed in Latin, since avowedly that "would fool 'em," and the other was a special certificate for a special course on the diseases of women and children. It is stated that these diplomas were dated two years back to "show additional experience." The attorney further states that the federal court found a bill of indictment against Decker for using the United States mails to promote a fraudulent scheme.

Virginia December Report

Dr. R. S. Martin, secretary of the Virginia State Medical Examining Board, reports the written and oral examination held at Lynchburg, Dec. 20-23, 1910. The number of subjects examined in was 9; total number of questions asked, 100; percentage required to pass, 75. The total number of candidates examined was 35, of whom 28 passed and 7 failed, including 1 osteopath. Eight reciprocal licenses were granted. The following colleges were represented:

PASSED College	Year Grad.	Per Cent.
George Washington University	(1909)	75
Howard University, Washington, D. C.	(1904)*	
College of Physicians and Surgeons, Chicago	(1908)*

Book Notices

Induced Cell-Reproduction and Cancer. The Isolation of the Chemical Causes of Normal and of Augmented, Asymmetrical Human Cell Division. By Hugh Campbell Ross, M.R.C.S. (Eng.), Surgeon, Royal Navy (Emergency List). Being the Results of Researches Carried Out by the Author with the Assistance of John Westray Croper, M.B., Assistant to the Research Department of the Royal Southern Hospital, Liverpool. Cloth. Price, $4.50 net. Pp. 423, with 129 illustrations. Philadelphia: P. Blakiston's Son & Co., 1911.

The object of this ambitious book is to present the details obtained by the study of living human cells under the microscope and the bearing of the results especially on the causation of cancer. The living cells, principally blood-cells, "are examined by placing them, under a cover-glass, on the surface of a film of jelly, which may contain dissolved in it any substance we may wish to experiment with, and which has, while in a molten condition, been poured on the microscopic slide and allowed to set there." The substance used in making the jelly is agar. It proving impossible to prepare permanent specimens by fixation of the jelly films, a rapid and ingenious method of photomicrography was worked out so that the appearances presented by the cells under observation could be reproduced accurately at any moment. The illustrations in the book have been made from photographs thus obtained.

Ross has found that by means of certain diffusible substances mixed with the jelly, leukocytes and other cells placed on the jelly may be caused to divide (once only) under the eye of the observer. This is the "induced cell reproduction." Such substances are called "auxetics," from the Greek meaning "exciters of reproduction." Among these substances are besides atropin and other alkaloids, xanthin, creatin, globin; now because these last and similar bodies occur in dead and disintegrating tissue, the cell proliferations of simple healing of wounds and of tumors are traced to the "auxetic" action of the bodies just mentioned—"the remains of dead tissue." On the basis of this notion chronic ulcers have been treated with applications of globin; the authors remark. "We think we can say safely that it causes more rapid healing of them than if they were treated in the usual way." The view that carcinoma is the result of "auxetics" the action of which is augmented by cholin, cadaverin and other putrefactive alkaloids and "the crucial experiment" are discussed in the last two chapters. It was found that normal serum has the power to restrain the "natural" auxetics from inducing cell-division and it was resolved to try to increase in the cancer patient the amount of this restraining body by injecting 6 ounces of defibrinated sheep's blood per rectum every morning. "The serum contains the restraining body, and it was argued that the red cells would be destroyed in the rectum, the hemoglobin decomposed, and in time the globin would become augmented by the action of the bacteria present. It was presumed that the restraining body of the serum, the auxetic in the globin and in the remains of the white cells, and lastly, the products of the decomposition would be gradually absorbed, and that they *might* raise the content of restraining body in the patients: in other words, they might act as a sort of vaccine." In the *two principal cases* in which this treatment was employed it is not known whether the patients had carcinoma or not; in both there seemed to be some temporary improvement. But the real "crucial test" was made on a patient with an ulcerating inoperable carcinoma of the breast; a part of the ulcer was treated with globin until the glistening malignant surface gave place to normal granulation tissue as shown by microscopic examination; a mixture of five parts of globin and one part of cholin was evaporated to dryness and small pieces applied to a minute area of the edge of the treated part of the ulcer. "In forty-eight hours a conical excrescence appeared at the seat of application" with "apparently new malignant cells." Ross freely admits that "this test is by no means conclusive."

Ross' studies of the behavior of living cells outside the body are of interest. That his "induced cell reproduction," which is the corner-stone of the whole work, is a real cell division of the same nature and significance as that which takes place in the body, is unproved. Successive generations of living cells must be produced *in vitro* before his claims on this point will stand.

So far as the applications of the observations to cancer are concerned, the credulousness of the author and the imprudence of the publishers' circular in speaking of the methods used as indicating "that the cause of cancer has been discovered and a way opened for successful treatment" cannot but cause amazement.

A System of Syphilis. In Six Volumes. Edited by D'Arcy Power, F. R. C. S., and J. Keogh Murphy, F.R.C.S. With Introduction by Sir Jonathan Hutchinson, F.R.S. By Various Authors. Cloth. Price, $13.50. Vol. V, pp. 356, with illustrations. Vol. VI, pp. 514, with illustrations. New York: Oxford University Press, 1910.

These two volumes, closing the "System," contain a group of articles which consider various special topics belonging to a complete exposition of syphilis. Being exhaustive articles on special subjects in syphilis, written by men of authority in the various fields, the contributions are all of them interesting and useful and some of them are notable.

Volume V contains "Affections of the Skin in Syphilis," by Phineas S. Abraham and Haldin D. Davis; "Ocular Syphilis," by C. Devereux Marshall; "Aural Syphilis," by C. Ernest West, and "Syphilis in the Upper Air Passages," by St. Clair Thomson. All of these authors are well known and their contributions are of the high character that would be expected of them. Each of the articles is very full: one may consult any of them for almost any fact in its scope, and they are thus exceedingly useful possessions for any medical library. They are all copiously illustrated, with colored illustrations for the most part. These illustrations, as those in the other volumes, constitute a valuable feature of the work. The English color prints of pathologic objects have not reached the remarkable excellence that we have become used to in recent German publications, but these are good and they serve their purpose of depicting for the reader the conditions which they are intended to portray.

Volume VI is unique, in that it brings together in one book a complete consideration of syphilis in the public services especially the army and navy. It is a very proper conclusion to such a system, and is an eminently valuable work.

Its scope is shown by the titles and authors of the various papers: "Introduction," by Sir Alfred Keogh, late Director-General of the Army Medical Service; "The History and Epidemiology of Syphilis in the More Important Armies," by Lieut. Colonel Charles H. Melville of the Royal Army Medical College; "Pathology and Microbiology of Syphilis as Applied to the Public Services," by Captain L. W. Harrison; "Clinical Course and Treatment of Syphilis in the Army," by Major C. E. Pollock; "Syphilis in the U. S. Navy," by Surgeon Charles N. Fiske; "The Epidemiology of Syphilis in the Royal Navy," by Fleet Surgeon E. P. Mourilyan; "The Practical Treatment Afloat of Syphilis in the Royal Navy," by Surgeon Charles K. Bushe.

It is evident from this enumeration that there must be considerable repetition in some of these contributions of matter discussed elsewhere in the "System," but this is a small objection in comparison with the very valuable lights thrown on the sociologic aspects of syphilis by a consideration of it from the standpoint taken in this work. Since syphilis first spread over Europe with the mercenaries of the army of Charles VIII of France, armies and navies have always been fruitful fields for syphilis, and this volume is a veritable thesaurus of knowledge in this field. We know of no single place where such a collection of knowledge of this sort is available.

In conclusion, a word of strong commendation should be said for the "System" as a whole. We believe that the time spent in reading its six volumes will be found very profitable in additions to the knowledge of even the well-informed reader, while many of the topics considered have been treated with so broad a view and contained so much of unusual information that their reading will afford the pleasure that comes from stimulated interest. The "System" constitutes a notable contribution to the permanent literature of syphilis and is an honor to British medicine. But it is more than that; such a monumental work can hardly hope for adequate monetary returns from its sales, so that its publication is a credit to the spirit which insured its issue and to the fine zeal for the advancement of knowledge of its editors and contributors. It is a work which highly deserves to be in every scholarly physician's library.

Three Contributions to the Sexual Theory. By Prof. Sigmund Freud, LL.D., Vienna. Authorized Translation by A. A. Brill, M.D., Clinical Assistant, Department of Psychiatry and Neurology, Columbia University. With Introduction by James J. Putnam, M.D. Paper. Price, $2. Pp. 91. New York: The Journal of Nervous and Mental Disease Publishing Co., 1910.

No man in modern neurology can boast of more ardent adherents and more violent enemies than Sigmund Freud, of Vienna. Not even his critics, however, can deny that he is a pioneer in a field hitherto but little cultivated. But while neurologists are discussing the merits and demerits of Freud's theories of the neuroses, the members of the medical profession as a whole know little of the points at issue. Unfortunately for the English reader, the German text of Freud's scattered articles is rather involved and abounds with a newly created, and therefore unknown, terminology. Hence the many misunderstandings. It is therefore well that the translation of the "Selected Papers on Hysteria and Other Psychoneuroses" has been followed by a translation of the "Three Contributions to the Sexual Theory." Whatever views one may hold concerning Freud's theories, it is essential that they be based on a first-hand acquaintance with the author's writings, not the least important of which is the present volume. As Putnam has already stated, no one can understand Freud's views until he has carefully read the several fundamental articles on which these are based. Brill's attractive translation of the present volume is the more welcome as it will have a tendency to moderate the tone of those of Freud's critics who only half-understood the author's meaning in the original German text. Careful reading of this interesting monograph carries the conviction that regardless of the question whether or not his psycho-analysis and mental catharsis will ever become popular, Freud has probed the innermost recesses of the normal and abnormal human mind. The contributions deal with (1) the sexual aberrations, (2) the infantile sexuality, and (3) the transformation of puberty. Psychologist, educator, jurist and physician will therein discover viewpoints on the sex-question which must stimulate further research in this hitherto neglected field.

Syphilis: Its Diagnosis, Prognosis, Prevention and Treatment. By Thomas P. Beddoes, F.R.C.S., Surgeon to the London Hospital for Diseases of the Skin. Cloth. Price, $2 net. Pp. 224. New York: Paul B. Hoeber, 1910.

In this work the author gives most of his attention to the cutaneous manifestations of syphilis. In addition, the clinical course, including the symptoms of the disease as a general infection, is given, but syphilis of the various structures besides the skin is given such brief consideration that the work can hardly be regarded as covering the subject of syphilis. For example, syphilis of the vascular system is given six small pages, about 1,500 words; syphilis of the bones, six pages; and that of the nervous system, including parasyphilitic diseases, five pages.

The author evidently has first-hand knowledge of syphilis, but, like so many of our English colleagues, is extremely careless in his manner of imparting it to others. Every cutaneous lesion, from roseola to ulcerating gummata, is a "rash." "The macule . . . is the first rash to appear." Of course a macule is an individual lesion and not a "rash." Such examples could be multiplied at length. The work cannot be said to be up to date. There is no distinct consideration of the serum-complement reaction in the diagnosis of syphilis; no reference to it in the index; and a rather careful reading of the work does not leave in our mind any memory of a single reference to it. Under prophylaxis no reference is made to Metchnikoff's important contribution to the subject—the most important contribution of recent years. Of course a work which leaves out such important additions does not satisfactorily represent the subject. Perhaps the explanation of the lack of consideration of these comparatively recent additions to syphilology lies in the fact that the work is older than it seems; an explanation that is supported by the observation that, while the publisher's imprint bears the date 1910, the author's preface is dated 1908—and these days knowledge is moving fast in syphilis.

The Mental Symptoms of Brain Disease. An Aid to the Surgical Treatment of Insanity, Due to Injury, Hemorrhage, Tumors and Other Circumscribed Lesions of the Brain. By Bernard Hollander, M.D. With Preface by Dr. Jul. Morel, Late Belgian State Commissioner in Lunacy. Cloth. Price, $2. Pp. 237. New York: Rebman Co., 1910.

In this work, the author deals with insanity based on focal lesions in the brain. Through the study and proper interpretation of symptoms, their mode of onset and associated conditions, he emphasizes the possibility of making a true pathologic diagnosis. Hollander cites many case records collected from various sources, including many of his personal observations, which demonstrate this possibility of localizing mental diseases. His study of these cases has enabled him to attach certain symptoms to lesions in the frontal lobes where the centers of perception and of special memories are located. He discusses lesions in the parietal, temporal and occipital lobes in a similar manner. The study of such mental diseases demands that one should be a close student of psychology. Dr. Hollander does not state that surgery should be employed in the majority of cases of insanity, but believes that a certain per cent. of these cases if studied early in their course may be greatly benefited by surgery.

Manual of Surgery. By Alexis Thomson, F.R.C.S., Professor of Surgery, University of Edinburgh, and Alexander Miles, F.R.C.S., Surgeon, Edinburgh Royal Infirmary. Vol. I, General Surgery. Pp. 886, with 339 illustrations. Vol. II, Regional Surgery. Pp. 861, with 227 illustrations. Third edition. Cloth. Price, $7. Pp. 861, with 227 illustrations. New York: Oxford University Press, 1909.

This is a comprehensive and systematic review of modern surgery, sufficiently detailed for the practitioner and not beyond the scope of the manual for students. It incorporates the important advances of the past two years, since the second edition, such as the Bier treatment, vaccine therapy, and the newer surgery of the peripheral nerves as worked out by Head and Sherren. Less attention is paid to description of operations than to careful description of symptoms, pathology and indications including principles of operating

The book is quite up to date in matter likely to be considered catch questions by examination boards, such as "snapping hip," "Madelung's deformity," and other rare conditions. The work is a standard compact summary of the best method of the Edinburgh school and should prove useful to medical students and practitioners everywhere. The illustrations consist of photographs and wood-cuts. The volumes are small and compact.

A Handbook of the Surgery of Children. By E. Kirmisson, Professor of the University of Paris. Translated by J. Keogh Murphy, F.R.C.S., Surgeon, Miller General Hospital for South East London. Cloth. Price, $7. New York: Oxford University Press, 1910.

This book may be considered as a compilation of surgical monographs, rather than as a treatise covering the subject. It presents, in a very attractive manner, a discussion of some of the more common surgical disorders of childhood which the general practitioner may be called on to treat. In the first part are considered congenital defects and malformations. This is a masterly presentation of the subject. In the chapters on fractures, however, while those of the upper extremities are discussed very thoroughly, it is difficult to understand why *some other common fractures are not mentioned* at all. For instance, fracture of the clavicle surely deserves some discussion among the fractures of children, but it is not mentioned. The book, however, will be of assistance to anyone who wishes to consult a special work on the surgery of childhood.

Lehrbuch der Urologie und der Krankheiten der männlichen Sexualorgane. Von Dr. Alfred Rothschild, Spezialarzt für Urologie in Berlin. Paper. Price, 13.50 marks. Pp. 522, with 162 illustrations. Leipsic: Dr. Werner Klinkhardt, 1911.

This book presents the merits and demerits frequently observed in the products of German authors; it is cyclopedic rather than concise, scholarly rather than didactic; it enables the reader to know many things, but to do few things; and its therapy is curiously incomplete. Thus tuberculin therapy and the entire subject of vaccine therapy receive each just enough space—three lines—to be named and dismissed without comment. That part of the book devoted to cystoscopy and urethroscopy is modern, and bears the stamp of personal experience.

Medicolegal

Evidence Barred in Nymphomania Case

The Court of Criminal Appeals of Texas holds, on the appeal of Jenkins vs. State (131 S. W. R., 542), a prosecution for rape on a female under the age of consent, that whether the prosecuting witness was laboring under the disease of nymphomania could not be established by the general reputation of *the blood relatives in the ascending line. On the trial she had* testified that she was about 13 years old; that she had voluntarily entered into the act of intercourse with the accused; that she had been doing such things ever since she was nine years of age, and with a great many persons. An examination by physicians showed a full development of parts, etc., but there was a division of opinion as to whether the girl was *a nymphomaniac, as contended by the accused*, or not. Whether, if her mother and blood relations were people of inordinate passions, it would predispose the girl to nymphomania, the court does not decide, but merely that there was no error in refusing to permit the accused to prove the general reputation for chastity of the mother and sisters of the girl, as that could throw no light on the issue before the court, because reputation is one thing, and the facts another.

The court also holds correct an instruction which told the jury that if they believed and found from the preponderance of the evidence in this case that the girl, at the time she testified in the case, was laboring under such a defect of reason from nymphomania or other disease of the mind, and under such derangement of the mind, as to render her incapable of receiving a sound mental impression of the transaction regarding which she testified, or if the jury believed that she had the capacity to receive such mental impression as would render it *impossible for her to retain and impart such impression* correctly, or if she was laboring under such defect of reason *from disease and derangement of mind* as would render it impossible for her to know and understand the nature and obligation of an oath, then in law she would not be a competent witness, and the jury should disregard her testimony altogether.

Furnishing of Water and Ice by Municipalities to Promote Health

The Supreme Court of Georgia says, in Holton vs. City of Camilla (68 S. E. R., 472), that the object in bringing, by means of a waterworks system, water *in pipes from a distance* for use in supplying the needs of a city, is not alone to obtain a sufficient quantity, but also to secure that which is freer from impurities than it is possible to obtain in the city itself. And if, in the hot season of the year, the inhabitants of the city must, for sanitary reasons, relinquish the cool draught from the well because, as has been demonstrated, wells of pure water cannot be maintained in populous communities, surely the city would have the right, were it practicable, to cool the water which it delivers through pipes as *a substitute, and which ofttimes is scarcely drinkable in its* heated condition. If not practicable to cool it in the pipes, and if it be necessary to the welfare, comfort and convenience of the inhabitants that its temperature be lowered before being used for drinking purposes, why cannot the city provide for the delivery of a part of it in a frozen condition, to be used in cooling such part of the balance as is used for drinking purposes? If the city has the right to furnish its inhabitants with water in a liquid form, the court fails to see any reason why it cannot furnish it to them in a frozen condition. *If in the hot climate in which the city of Camilla is* situated ice is necessary for the comfort, health and convenience of its inhabitants, why should not the city be permitted to furnish ice to its inhabitants? And if the furnishing of ice to its inhabitants is conducive generally to their health, comfort and convenience, it is certainly being furnished for a municipal or public purpose. It is a well-known fact that one of the main uses to which ice is put is the cooling of water for drinking purposes; and when it is used for this purpose, if impure, it is as apt to be deleterious to the consumer as any other impure water. Why, then, in the exercise of its police power, may not a city guard against impurities in the ice, as well as the water, used by its inhabitants? Nor does the court see any rational objection on the idea that the city will be engaging in a manufacturing enterprise. The city might perhaps equally as well be said to be manufacturing when by the use of a filtering process it changes impure water into that which is pure.

Proof of Death

The United States Circuit Court of Appeals, Ninth Circuit, says, in Northern Pacific Railway Co. vs. King and others (181 Fed. R. 913), an action brought by the latter parties to recover for the alleged wrongful death of one H. A. King, that the fact of one's death may be proved by circumstantial evidence, provided the facts and circumstances going to show *such death* be *sufficiently* strong. It is also true that under some circumstances the fact of death, as well as of birth, marriage, pedigree and the like, may be proved by hearsay evidence. It has been held by many courts that the death of an individual, though *disconnected with any question of* pedigree, and for whatever purpose sought to be established, may be proved by hearsay, subject to the same restrictions that are applicable to cases where matters of pedigree are involved. But the court knows of no case which holds that it is competent to prove the basic and controverted fact by hearsay testimony, pure and simple, under circumstances like those *presented here*, where the *accident resulting in the* injury of H. A. King had but recently occurred, and whether or not it resulted in his death was susceptible of easy proof. As a matter of course, no inference of his death could be properly drawn merely from his injuries and the amputation of one of his legs, it having been affirmatively shown that he survived such injuries and amputation for a week or ten days.

Employment of Physician by One Member of County Board

The Supreme Court of Oklahoma holds, in Mahr vs. Board of County Commissioners of Pottawatomie County (110 Pac. R. 751), that one member of a board of county commissioners cannot bind the county to pay for the services of a physician in attending on the poor without first having been authorized thereto by the majority of said board whilst in session. The plaintiff set forth that the defendants were indebted to him in the sum of $423 for professional services as a physician and surgeon rendered and performed in giving medical care to the poor and paupers and county charges in the city of Shawnee and vicinity thereof. He further alleged that all and each item of such services were rendered in case of an emergency, that is, in which the patient was in absolute need of medical attention, and at the time of the rendition of such services there was no physician in the employ of the city of Shawnee and vicinity, and that in each the services were performed at the instance of one of the commissioners of said county, said city being within his district. But the court, for the reason first above stated, holds that a demurrer was properly sustained to this cause of action, as it was not alleged that, by any resolution of the board of county commissioners, this one commissioner was authorized to employ the plaintiff to perform the services herein sued for.

ASSOCIATION OF AMERICAN MEDICAL COLLEGES

Annual Meeting, held in Chicago, Feb. 27-28, 1911

The President, DR. J. A. WITHERSPOON, Vanderbilt University, Nashville, Tenn., in the Chair

A list of the officers elected at this meeting was published in THE JOURNAL, March 4, 1911, p. 678.

The following amendments to the constitution were adopted:

Amendments

ARTICLE III: SECTION 1.—Every college holding membership in this association shall, on and after Jan. 1, 1912, require for matriculation a completed or unconditioned medical student's certificate, to be granted by a state medical examining and licensing board, or a board empowered by statute to grant such certificates, or a certificate of entrance to the academic department of any state university, or a certificate of entrance to an accredited university or college, providing that said certificate is granted on no less than the following requirements:

(a) A baccalaureate degree from an accredited college or university.

(b) and (c) Unchanged.

(d) and (e) Eliminated.

SECTION 2. This examination must be conducted by or under the authority of the board of medical examiners of the state in which the college is located, or by a duly authorized examiner of the college entrance examination board, or the authorized examiner of an accredited university, state or otherwise, or by an examiner whose certificates are accepted by accredited colleges or universities, or by a method approved by the judicial council of this association.

SECTION 3. The term "accredited" as applied to high schools, academies, colleges and universities means institutions of that type that have been investigated and are accredited by the State University of their respective states, or by the North Central Association of Colleges and Secondary Schools, the Association of Colleges and Preparatory Schools of the Southern States, the Association of Colleges and Preparatory Schools of the Middle States and Maryland, the New England College Entrance Certificate Board, the Association of American Universities and the Association of State Universities, provided that such accrediting is based on Article III, Section 1, of this constitution.

SECTION 4. Colleges in membership in this association may honor the official credentials presented by students from other colleges having the standard requirements maintained by members of this association, excepting for the fourth year of their course, but no member of this association shall admit a student to advanced standing without first communicating with the college from which such student desires to withdraw, and receive from the dean, secretary or registrar of such college a direct written communication certifying to the applicant's standing. Credit for time or scholarship cannot be given beyond that of the college issuing the credentials, except by mutual agreement between the colleges.

SECTIONS 5, 6 and 7. Unchanged.

SECTION 8. Each student shall be obliged to attend not less than 80 per cent. of the exercises in every annual course of study for which he seeks credit. No student shall be given credit on examination unless he attains a grade of at least 70 per cent. or its equivalent in any other marking system. And no student shall be graduated unless he shall have attained a passing grade in each and all subjects of the required curriculum.

ARTICLE V: SECTION 1.—The entire course of four years shall consist of at least 4,000 hours for each student, and shall be grouped in divisions and subdivided into subjects; each division and subject to be allotted the number of hours as shown in the following schedule:

DIVISION 1.—ANATOMY, 720 Hours (18 Per Cent.)

	Hours.	Lect. Rec. Dem.	Lab. Wk.
(a) Gross anatomy (including applied anatomy)	510	120	390
(b) Histologic and microscopic anatomy	135	30	105
(c) Embryology	75	30	45

DIVISION 2.—PHYSIOLOGY AND CHEMISTRY, 600 Hours (15 Per Cent.)

	Hours.	Lect. Rec. Dem.	Lab. Wk.
(a) Inorganic chemistry	180	60	120
(b) Organic chemistry	75	30	45
(c) Physiologic chemistry	104	30	75
(d) Physiology	240	140	100

DIVISION 3.—PATHOLOGY, BACTERIOLOGY AND HYGIENE, 450 Hours (11.25 Per Cent.)

	Hours.	Lect. Rec. Dem.	Lab. Wk.
(a) Bacteriology	135	30	105
(b) Hygiene and general dietetics	45	45	...
(c) Pathology	270	60	210

DIVISION 4.—PHARMACOLOGY, MATERIA MEDICA AND THERAPEUTICS, 240 Hours (6 Per Cent.)

	Hours.	Lect. Rec. Dem.	Lab. Wk.
(a) Pharmacology	105	40	65
(b) Materia medica and pharmacology	80	...	...
(c) Therapeutics	55	...	...

DIVISION 5.—MEDICINE AND MEDICAL SPECIALTIES, 970 Hours (24.25 Per Cent.)

	Hours.	Lect. Rec. Dem.	Lab. Wk.
(a) General medicine (including clinical microscopy)	640	..	...
(b) Pediatrics	150	...	...
(c) Nervous and mental diseases	105	...	...
(d) Jurisprudence, ethics and economics	30	...	...
(e) Dermatology and syphilis	45	...	...

DIVISION 6.—SURGERY AND SURGICAL SPECIALTIES, 720 Hours (18 Per Cent.)

	Hours.	Lect. Rec. Dem.	Lab. Wk.
(a) General surgery	510	...	...
(b) Orthopedic surgery	45	...	...
(c) Genito-urinary diseases	45	...	...
(d) Eye	60	...	...
(e) Ear, nose and throat	60	..	...

DIVISION 7.—OBSTETRICS AND GYNECOLOGY, 300 Hours (7.5 Per Cent.)

	Hours.	Lect. Rec. Dem.	Lab. Wk
(a) Obstetrics	195	..	..
(b) Gynecology (including some abdominal surgery)	105	...	...

Colleges may reduce the number of hours in any subject not more than 20 per cent., provided that the total number of hours in a division is not reduced. Where the teaching conditions in a college are best subserved, the subject may be, for teaching purposes, transferred from one division to another. When didactic and laboratory hours are specified in any subject laboratory hours may be substituted for didactic hours.

Section 2. Each college in membership in this association shall print in every annual catalog or announcement a table of the total number of hours' work given in said college arranged both by subjects and years.

Section 3. Each college in membership in this association shall print annually a list of its students by classes.

Article VIII: Section 1.—The stated meetings of this association shall occur annually at such place as the association may designate by vote, the time of meeting to be set by the officers and judicial council of the association.

(To be continued)

PHILADELPHIA COUNTY MEDICAL SOCIETY

Meeting held Feb. 22, 1911

The President, Dr. C. B. Longenecker, in the Chair

Dr. T. J. O'Drain read a paper on "Ischemia versus Bier's Passive Hyperemia."

Dr. Robert H. Ivy, read a paper on "Industrial Phosphorus Poisoning."

Breaking Down of Wounds Following Operations

Dr. John J. Gilbride: The breaking down of wounds following operations is caused by infection. Since the application of iodin for sterilizing the skin it is also used by surgeons in the preparation of their hands. One of the best means of preventing suppuration of wounds is to have them dry. The unnecessary use of hemostatic forceps which "chew" and devitalize the tissues should be avoided. Iodin catgut is now much in favor. The use of large-sized suture material is undesirable. Undue tension should not be placed upon the sutures nor should they be placed too closely together. The so-called stitch abscess has occurred, in my experience, most frequently when the cutaneous stitches were left in for a longer period than three or four days. I further believe that not a few wounds, by displacement of dressings, hands of patients, etc., become infected subsequent to operation. It is not possible to prevent all wounds from breaking down, but perhaps, by a little closer application of old facts one may lessen the number of wounds that break down through infection.

DISCUSSION

Dr. John A. McGlinn: All of us who have no fear of telling the truth have trouble with our wounds. Doubtless since the use of iodin, infections have been less. The fewer assistants a man has when operating the less likely is he to have infection. The use of retractors is also a factor in the production of infection. It is much better to have the patient well relaxed and have the incision sufficiently large than to have the sides of the incision forced back with retractors. In dealing with pus cases in the pelvis it is advisable not to have great pressure on the sutures.

Dr. L. Jay Hammond: It has always seemed to me that a potent factor in wound infection is an excessive amount of dressing applied over the abdomen, and for a number of years I have made this dressing rather scant, using only sufficient to cover thoroughly the surface and not to add to body temperature. My feeling regarding the iodin treatment is that it has no advantage over other methods, and is only an additional agent to trust to the hands of our nurses who are already overburdened with technic. For fear of strangulation of tissue, I use as few sutures as possible, and, when the abdominal walls are not too fat, I prefer the use of the through-and-through suture.

Tinea Favosa

Dr. Leonard D. Frescoln: This is a vegetable parasitic infectious disease, generally of the scalp, called contagious by most text-books, but better limited to the term infectious according to modern terminology; not taken from mere surrounding atmosphere of patients and not very readily, as seen in the hospital, from living long with patients. The etiologic factor known is the *Achorion schönleinii* found in 1839, and named by Remak. Many of the mycelia and spores make up the characteristic "scutulum," a sulphur-like cup having the odor of mice, from which the disease may be contracted. Some cases have involvement of parts other than the scalp, as nails, trunks, knees (Fox) and mucous membrane (Kaposi). The affection is liable to be confounded with ringworm. Apart from the characteristic lesions of favus the microscope shows the large mycelium branching and broad spores. The disease is said, by Peyritsch, to take from three to six weeks for its development. It is very refractory to treatment, some cases lasting years; bald spots are a frequent evidence of the disease. In treating we soften the lesions with 5 per cent. carbolized petrolatum. epilation is practiced, sulphur or chrysarobin preparations are used. The best treatment is a long Roentgen-ray exposure repeated. Carbon-dioxid snow has been used with uncertain results. I recently excised a lesion to hasten cure. Favus is one of the deportable diseases, with a fine, in the United States. If a patient is not at once deported he must be under treatment until cured and remain so a month at least. Crocker says: "The disease may be considered cured when after six weeks' discontinuance of treatment there is no localized scaliness." Of course, some cases are very pitiable, but care must be exercised in handling immigrants. Twenty-six of forty-eight patients at our hospital were Russians; average age, 13½ years.

1. **The Midwife Situation.**—In reviewing the midwife situation abroad and in this country, Emmons and Huntington found two standards of skill and a divided responsibility. The midwife must either be a competent, trained obstetrician, or she must become a subordinate, cooperating with the obstetrician, as does the trained obstetric nurse, relying on his judgment and leaving with him the responsibility of the two lives, before a system harmonious and satisfactory can result. The authors believe it to be the duty and the privilege of the obstetricians to safeguard the mother and child in the dangers of childbirth. The obstetricians are the final authority to set the standard and lead the way to safety. They alone can properly educate the medical profession, the legislators and the public. A resolution of the Women's Municipal League awaits only a formal endorsement to urge the importance of legislation, not for the licensing and regulating of the midwife, but for such minor changes in the laws as will make the present statutes effective in dealing with the midwife in Massachusetts. It has remained for this and other charitable organizations to point out the necessity for bettering obstetric conditions in the state. Let the medical profession, they urge, not only cooperate with these forces for good, but let obstetricians consider well the situation in obstetrics throughout the state to-day; let them look into the future and consider means of furnishing efficient trained service to rich and poor alike.

2. **Dislocation of the Hip.**—The points especially emphasized by Monks are (1) for practical purposes, all regular dislocations of the hip are, in reference to the acetabulum, either posterior or anterior; and (2) whichever the dislocation, an imaginary arrow on the exposed surface of the lower leg pointed toward the flexed knee will, in case the Bigelow method of replacement is to be used, remind the surgeon during the flexion whether to make the knee describe an inward or an outward curve.

7. **Bacillary Dysentery.**—It has been shown that bacteria acting on protein (nitrogenous substances), in the absence of fermentable carbohydrate, form putrefactive products, some of which may be very toxic. The dysenteric flora is essentially putrefactive in character. These products are absorbed in part, at least, from the alimentary canal, paired in the liver and excreted through the kidneys. The patient, therefore, in receiving no food, is being poisoned by the bacterial products elaborated in the intestinal tract, and attempting to detoxicate and excrete these substances in addition to maintaining the normal vital functions of respirations, heart beat and so on. Realizing these conditions, Kendall proposes feeding such patients from the start with carbohydrate. The principle involved is a twofold one: to furnish an easily assimilable and readily fermentable carbohydrate to change the character of the bacterial activity in the alimentary canal from the proteolytic to the fermentative type, and to furnish nourishment to the patient. The patient is first given a dose of castor oil or other cathartic to clean out the intestinal tract thoroughly. All food except sterile water is withheld for from twelve to fifteen hours to facilitate this cleaning out. Lactose, 5 per cent. solution in sterile water, is then fed by mouth for several days, until the acute symptoms abate, or until it becomes apparent that the patient requires some nitrogenous food. Whatever nitrogenous food is selected must be given cautiously, in small amounts, simultaneously with an excess of utilizable carbohydrate to protect it from bacterial attack. The lactose should be fed in rather small amounts, often repeated, to keep up a stream of this sugar in the alimentary canal, otherwise the proteolytes will be able to attack whatever nitrogenous substances may be present in the alimentary canal between the doses of lactose. Dextrose (Kahlbaum's) may be infused, preferably as a 2.5 per cent. solution in physiologic salt solution to bring to normal the dextrose content of the blood and to furnish fluid to the patient. This feeding of lactose is intended to accomplish a twofold purpose: to furnish to the host a readily assimilable food, requiring a minimal expenditure of energy to metabolize it, and to change the character of the metabolism of the dysenteric flora from the proteolytic to the fermentative type. This change in the type of the intestinal flora is particularly desirable to prevent further intoxication of the host and to give him a better chance to combat the poisons already absorbed.

8. **Infectious Diarrhea.**—The plan of treatment outlined by Bowditch is based on a trial in thirty-nine cases of children, from 3 to 16 months of age. They were not taken "*in serium*," but were chosen where some hope of life and chance for study existed. Of these, practically 50 per cent. died (nineteen). The duration of disease on admission varied from one to sixty days (an average of twelve) in the fatal cases; of those who recovered, from one to twenty-eight days (an average of eight days). Treatment was divided into: (1) the initial attack on the specific organisms and their resultant symptoms; (2) treatment of supplementary symptoms and supportive treatment. The former consisted of catharsis, using castor oil, calomel and sodium sulphate, colonic irrigations with normal saline solution, plus lactose or dextrose, adding silver nitrate or tannic acid, if necessary—gastric lavage only when necessary. Temporary abstinence from all nutrition is imperative. This period lasts theoretically until the infection has subsided, temperature has fallen and the nervous irritability of the gastro-intestinal tract has improved. During this time ingestion of water is necessary to keep the fluids of the body and blood as normal as possible. Boiled water amounting to the quantity of food usually ingested is given by mouth. Lime water and alkalies have been added according to the digestion.

Of the thirty-nine children herein reported, all received sterile water for not more than three days (an average of two) in contrast to the usual prolonged starvation. After this short interval they received 5 per cent. lactose. Of the twenty discharged well and the nineteen who died, fourteen and ten, respectively (58 per cent.), received lactose up to 5 per cent. for an average of eight days. Seven of these died during the treatment. The temperature fell in seventeen and remained stationary or increased in seven. The movements diminished in thirteen and increased in eleven. Blood was increased in seventeen and diminished in five. Of those who recovered, an average of 25 ounces of sterile water was well taken, while barely 17 ounces was ingested by those who died. Lactose solution (5 per cent. administered for an average of eight days) was readily taken by all to an average quantity of 36 ounces. Of the remaining fifteen, two died before lactose administration was given. Six received whey (an average of 40 ounces in six days), while the remaining seven were given various foods and subsequently died. Seven of the twenty who recovered received at first dilutions of sterilized fat-free milk strengthened slowly to whole milk; three got whey at first, later straight dilutions of milk; five got buttermilk, and three got straight dilutions of sterilized milk to whole milk. Of the ten fatal cases that continued through the lactose administration, no definite result in regard to food can be stated. The majority of the children succumbed to the too early administration of milk or too rapid change of nourishment. The reason for the too early giving of food was the necessity for some nitrogenous nourishment to sustain life. Toxemia was fought largely symptomatically. The stimulants were mostly given hypodermically. Brandy was seldom used. Strychnin, from 1/250 to 1/500 grain, was given when cardiac failure was imminent. Bowditch says that lactose and dextrose in the irrigations gave no demonstrable therapeutic value, and that dextrose infusions were certainly an improvement.

9. **Treatment of Infectious Diarrhea in Infants.**—During the last season at the Boston Floating Hospital colon irrigations of 3 per cent. silver nitrate were employed in the treatment of infants ill with infectious diarrhea. The technic of the irrigation did not differ essentially from that of ordinary irrigations. Smith says that it is advisable, however, to clean the rectum, and as much of the colon as possible, before using the silver nitrate solution. A cleansing irrigation with sterile water is given and continued until the water comes back clear. Salt solution should not be used for this preliminary cleansing, since the sodium chlorid forms with the silver nitrate an insoluble silver salt which is precipitated and the strength of the silver solution is weakened. When the cleansing has been completed, 1 pint of a 3 per cent. silver nitrate solution is allowed to run into the colon and the tube then withdrawn. Some of the solution will be expelled, but no attempt is made to recover the entire amount used. In adults there is considerable pain after the injection, but none of Smith's patients showed any marked evidence of discomfort.

The treatment was used in thirty-two cases. None of the patients was in any way harmed by the treatment. Three infants showed a rather severe reaction, but it was only temporary in character. In twenty-two of the cases, treatments were given early in the disease. Eighteen of these patients were improved by the procedure, eleven markedly so, and seven slightly. Six patients were given the injection late in the disease; three, or one-half, were benefited. In six cases no report can be made. Smith claims that in a certain number of cases of infectious diarrhea in infants, an early colon injection of 3 per cent. silver nitrate solution apparently hastens the disappearance of blood and pus from the stools and shortens the course of the disease. In some late cases, when blood and pus persist in the movements, the ulcers can be stimulated by silver nitrate injections and the stools cleared.

12. **Two Methods of Obtaining Human Milk for Hospital Use.**—The hospital of the Massachusetts Infant Asylum, which uses the method of most foreign hospitals, has resident wet nurses who are part of the organization of the institution. These women are secured from other charitable institutions, and from the lying-in hospitals. They are not permitted to do any heavy work or scrubbing, but should only dust a certain number of rooms and do their own washing. They are allowed to have as much as they want of a liberal diet, which costs the hospital from 43 to 45 cents a day for each person. The milk of these wet nurses is used in two ways: (a) The milk is drawn with breast pumps for the very weak and delicate babies. It is placed in sterile jars and kept in an icechest until used. (b) The stronger babies are put to the breast. The amount of milk taken is recorded by a trained nurse, who weighs the baby before and after the nursing. The women are paid according to the amount of milk they supply, at the rate of 2 cents an ounce for "drawn breast milk" and 1 cent an ounce for nursed breast milk, up to a limit of $16 a month. The Boston Floating Hospital collects the milk from nursing mothers in the tenement district. Precautions are taken to have the milk drawn in a cleanly manner and put in sterile bottles and then kept at a low temperature. The women are paid at the rate of 60 cents a quart.

13. **Diarrhea in Infants Associated with the Gas Bacillus in Stools.**—In the opinion of the authors there exists a group of diarrhea in infants impossible to differentiate clinically from infectious diarrhea caused by the dysentery bacillus. These cases are associated with the presence of large numbers of gas bacilli in the stools. The bacilli occur in such numbers and in such relations that it seems reasonable to believe that they are the etiologic factor of the diarrhea. This diagnosis, when made, gives the indication for treatment with buttermilk.

18. **Method for Relief of Odynphagia.**—Some time ago Howell claimed that relief of laryngeal pain may be secured by firm pressure on the ears and mastoid region in swallowing. Hald tried this method in thirty-three cases of inflammatory diseases of the tonsils and their surroundings. In twenty-four cases pain was considerably relieved by pressure against the tragus, or against the upper part of the mastoid. Tragus pressure was most efficient. He explains the process by supposing that it exercises a strong counterirritation of the skin area, whose sensitive nerve supply is in intimate relation to the sensitive nerve supply of the diseased tonsil. He limits the area to the lateral portion of the posterior meatal wall.

19. **Aneurysm of the Heart.**—In Betts' case the aneurysm arose from a gradual occlusion of the coronary artery by atheromatous changes. There was extreme generalized arteriosclerosis, not caused by syphilis. The diagnosis was made post mortem.

22. **Melted Iodoform Ointment in Treatment of Suppurative Bubo.**—The principle of the treatment employed by Royster is that of attempting to promote resolution of the inflamed glands, to secure rapid pointing, if suppuration occurs, and, finally, to evacuate the pus and fill the cavity with melted iodoform ointment. When the inguinal swelling first begins, daily application is made of a salve composed of equal parts of pure ichthyol and the official ointments of iodin, mercury and belladonna. A small portion of this is rubbed in well and another portion spread thickly on a gauze dressing, which is held tightly against the area by a spica bandage. If absorption fails to take place and breaking down ensues, as generally happens, the following procedure is carried out, when the suppuration is at its height. A spot on the softest and most prominent part of the swelling is infiltrated with a 1 per cent. cocain solution and a very small incision made here with a bistoury—an opening just large enough to let out the pus. When the cavity has been emptied by the aid of pressure it is washed out two or three times with hydrogen peroxid, diluted one-half with sterile water, followed by flushing with sterile water alone. For these washings an ordinary glass piston syringe is used. A quantity of 10 per cent. iodoform ointment is now melted (it can conveniently be done in a large spoon over a gas, alcohol or oil flame), sucked up into the same syringe, and injected into the suppuration cavity with some force, so as to completely fill it. Over this is immediately placed a cold bichlorid of mercury gauze compress, which is retained by the spica bandage, as before. The dressing is not disturbed for five days. At the end of this time it is removed and the excess of ointment is squeezed out; if any pus remains a second injection of ointment is made; otherwise the gauze and bandage are reapplied for some days longer. In the majority of cases one treatment suffices to cure. Ischiorectal abscess, while not at all related to bubo, affords an opportunity of applying the method just outlined, thereby saving the patient time and trouble.

23. **Is Cancer Contagious?**—White reports five cases of cancer, four of which terminated fatally, three occurring in one house and two in another; all the patients were blood relations or lived in close contact with one another, as husband and wife. All have been infected within five years.

39 Phrenology and Its Founder: The Claims of Franz Joseph Gall on the Homage of Scientific Posterity. J. Knott, Dublin.

33. **Diet in Heart Disease and Arteriosclerosis.**—The importance of proper diet in heart disease is emphasized by Bishop. He says that in acute heart disease, the simplest and best diet to begin with is a milk diet, but that must very soon be supplemented by other simple and nutritious foods. In chronic heart disease the quantity of food should be reduced to the amount necessary for the maintenance of the body, the weight, and strength. The food should be divided into five small meals, the largest meal being taken in the middle of the day. The food should also be as dry as possible. In considering a specific choice of diet in heart disease, he divides the cases sharply into two classes. There are those cases in which, on account of a lesion of the heart of a mechanical nature, the welfare of the patient depends on the maintenance of a healthy heart muscle, able to do an extra amount of work. In these cases the problem is the same as that presented by patients suffering with tuberculosis or any other condition in which

the maintenance of health depends on the maintenance of resistance. In these cases, also, diet must be reasonable, but there is no necessity for careful chemical observation. The second class of cases, and the one which Bishop considers, is that in which the heart trouble is part of a general cardiovascular disease, and is of chemical, or at least toxic, origin.

34. **Trachoma.**—Brav feels that the data with reference to the *contagiousness of trachoma are exaggerated*. He is convinced that trachoma is not so contagious as it has been thought to be, and that it is a curable disease. Only neglected cases terminate in a reduction of vision. In this country, it never leads to total blindness, except, perhaps, among the Indians. Inasmuch as there is no trachoma problem in our country, laws on this subject, he thinks, need not be oppressive. Trachoma is not on the increase, but rather on the decrease. To create fear among the laity to the existence of imminent danger resulting from trachoma, which is purely imaginary, Brav believes, is entirely unscientific and harmful to the best interests of the community.

51. **Congenital Deformities.**—The interesting points in the necropsy findings of Kingsley's case were a very inconspicuous thymus, there being practically no tissue where the gland should be; normal heart valves, but an open ductus Botalli, measuring about 1 millimeter in diameter; an acute diffuse cellular myocarditis; no special hypertrophy of the ventricles; scattered areas of bronchopneumonia in both lungs. The left ureter appeared normal at its entrance into the bladder and as far as followed up to the brim of the pelvis. Here it was lost and no remnant of kidney tissue was found in this area. The left adrenal was close to the diaphragm and appeared normal. The right kidney was very large, about the size of two normal kidneys. There was a single distorted pelvis coming from the anterior median portion of the irregular kidney mass, the long axis being nearly parallel with that of the vertebral column and lying almost completely to the right of the vena cava, which crossed over its mesial surface. The kidney looked in no way abnormal. An acute enteritis throughout the ileum was found. The thyroid was small, pale, and uniform on section. The bone marrow appeared normal. Permission to examine the brain could not be obtained.

63. **Operation of Abdominal Myomectomy.**—Some interesting mortality data are furnished by Mayo in his review of cases of uterine myomata operated on by himself and Charles Mayo during the past ten years. These statistics include all varieties of operations and the various complications, such as cancer, tubal infections, necrosis and degenerations of the tumor, etc. Every patient dying in the hospital, irrespective of the cause of death or the length of time following operation, is counted as dying from the operation. Total number of operations for uterine myomata, 1,244; deaths, 30, or 2.3 per cent.; number of cases of myomata of the uterus which necessitated total abdominal hysterectomy, usually because of malignant degeneration or acute infection, 66; deaths, 2, or 3 per cent.; number of supravaginal hysterectomies, 900; deaths, 23, or 2.5 per cent.; number of abdominal myomectomies, 157; deaths, one, or ⅔ of 1 per cent.; vaginal hysterectomies, 77; deaths, 2, or 2.75 per cent.; vaginal myomectomies, 50; deaths, 2, or 4 per cent.

67 and 70. Abstracted in The Journal, Jan. 14, 1911, pp. 140 and 141.

68. **Functions of the Great Omentum.**—As a result of his studies, Rubin claims that the omentum has no spontaneous motility. The displacements of the omentum may be explained by: (a) intestinal peristalsis; (b) intra-abdominal tension; and (c) the static condition of the stomach and colon and of the small intestine; (d) the anatomic relationship of the omentum to the gall-bladder and spleen. The omentum has no demonstrable "chemotaxis." The amount of intraperitoneal fluid plus the amount of gas contained in the large intestine account for this apparent intelligent retreat of the omentum from virulent infective processes. In addition the suction action of the diaphragm under changed conditions of intra-abdominal tension explains the apparent upward "chemotaxis" of the omentum in inflammatory lesions of the upper abdomen. The omentum has no intelligent and spontaneous protective rôle. Such protection as it apparently displays is simply due to its properties as peritoneum, and not as a superior organ with definite functions. It cannot restore vitality to necrotic organs nor vascular supply to those deprived of their circulation. The end-product of an adhesion between the omentum and a foreign body is the destruction of the foreign body; between the omentum and any other abdominal viscus is scar tissue. The omentum does not invariably repair spontaneously defects in hollow or

investigated in the second case. For certain periods the patient was allowed a somewhat restricted diet, containing gluten bread, supposedly starch-free, but actually, on analysis in the laboratory, yielding 32.5 per cent. starch. For the first ten days the food was not measured accurately enough to allow complete figures of food value to be stated; but from March 21 to April 9, each article was carefully weighed and its value computed, mainly from Atwater's tables, partly from analyses made in the laboratory. Very little restriction, except of carbohydrate, was enjoined during the period of liberal diet, and at all times the patient was allowed to roam about the wards, under surveillance, to prevent secret taking of food or loss of urine. The absolute reduction in sugar output as soon as the patient was put on v. Noorden's gruel was striking, and was in perfect accordance with the claims of v. Noorden and the experiences of other workers. In both cases, however, acetone, which was practically never present during the periods of glycosuria, invariably appeared after administration of the oatmeal gruel.

Clinically associated with this were symptoms suggesting acidosis, such as nausea, rapid pulse and headache; the ferric chlorid reaction, however, generally was absent. Since it is very unusual for acidosis to follow the use of v. Noorden's gruel, it was thought that the quantitative determination of the nitrogen and ammonia output might explain the apparent deviation from the usual reported reaction. There was a relative increase of ammonia each time the v. Noorden diet was given, but the nitrogen excretion always fell markedly because of a low protein intake. The figures representing total ammonia vary considerably and are not in agreement with the percentage curve. In fact, during the periods when the ammonia was 10 per cent. of the total nitrogen, the actual ammonia output was lower than it was at any other time during the period of observation. It is probable that the increased ratio is due to the low total nitrogen excretion, corresponding to the sudden diminution in the nitrogen intake. But the figures at the first and last v. Noorden period show an absolute increase of ammonia. After three days of the gruel, 4 grams of ammonia, or 22 per cent. of the total nitrogen, were excreted in the urine, and with the reduction of the glycosuria after the gruel later, the actual as well as the relative ammonia elimination was increased. The use of fresh vegetables and the v. Noorden gruel resulted in raising strikingly the patient's tolerance for carbohydrates and in reducing considerably the degree of acidosis. These two cases of traumatic diabetes ran a milder course than is usually seen in diabetes in children, but otherwise in their urinary and therapeutic reaction they did not differ essentially from cases of diabetes of non-traumatic origin.

92. **Biot's Breathing.**—During the past two years, in the course of a more or less systematic graphic study of pathologic types of breathing, Conner has encountered typical examples of Biot's type of respiration seven times. In six instances it occurred in the course of meningitis; in the seventh, it was found in a child suffering from some intracranial complication of suppurative mastoiditis, the nature of which could not be determined. The characteristic features of this form of respiratory arrhythmia may be stated as follows: (1) periods of apnea, which vary in length and occur at irregular intervals; (2) constant irregularity in rhythm, and in the force of the individual respirations; (3) frequent occurrence of deep sighs; (4) great uniformity of the expiratory level, a point noted by Conner and one not previously described.

94. **Interrelation of Organs of Internal Secretion.**—Hoskins says that most of the available evidence indicates that the thyroid stimulates the adrenals. Hypothyroidism causes hypertrophy in the pituitary, probably due to a vicarious assumption of thyroid function. It is fairly well demonstrated that there is a relation between the thyroid and the gonads, which are probably stimulated to normal activity by the former. The frequent association of abnormal conditions in the thyroid and thymus points toward a relationship between them, but definite evidence on the point is meager and conflicting. The theory that the thyroid inhibits the pancreas is probable, but more data are needed.

96. **Congenital Syphilis of the Heart.**—It is stated by Warthin, that gumma of the heart is rare in congenital syphilis, but that congenital syphilis of the heart, in the form of a localized or diffuse interstitial myocarditis, is most probably not rare. The new criterion is the demonstration of the *Spirochæta pallida* in the proliferating interstitial tissues of the heart wall. Adler could base his diagnosis of syphilis only on the endarteritis. Warthin has shown that the same type of interstitial myocarditis in the absence of coronary endarteritis is syphilitic, by demonstrating that these light-staining patches of proliferating stroma represent localized colonies of the spirochete and that the organism occurs in such patches in extraordinary numbers. The myocarditis described by Coupland, Hektoen and Le Count, Warthin believes to be of the same type, sufficiently localized in the cases reported by the last two writers to be visible to the naked eye and to be interpreted as gummata. In all cases of cardiac disturbances in children, congenital syphilis should be carefully considered as a possible factor.

Warthin's series of cases also show that it can be a cause of asphyxia neonatorum and unexplained sudden death in infancy. Under such circumstances, the possibility of congenital cardiac syphilis must be borne in mind and a thorough microscopic study of the heart carried out. The same thing is true of cases of non-development, infantilism, chronic valvular lesions in children and young adults, etc. For all of these conditions an etiology of congenital syphilis of the heart is possible, and the diagnostic criterion is the demonstration of fibroblastic areas in the heart wall containing colonies of spirochetes. Congenital syphilis of the heart occurs most frequently in the form of a diffuse interstitial myocarditis due to the presence of the *Spirochæta pallida* in large numbers, without ordinarily producing characteristic macroscopic changes so that the absence or presence of congenital cardiac syphilis can be told only by a thorough microscopic examination of the heart wall.

107. **Thrombokinase.**—Believing that it would be interesting to take animal extracts and use them locally, Strong employed Batelli's method which consisted in extracting the tissue of the lung of the sheep with distilled water or salt solution, and then precipitating it with a very weak percentage of acetic acid; then centrifuging the precipitate, evaporating and adding alcohol to preserve it. He found that alcohol did not render it perfectly sterile, so he tried 1 per cent. thymol, and evaporated the precipitate at a low temperature with the electric fan, and then added an equal bulk of 1 per cent. thymol in alcohol. In order to determine if there was anything specific in the powder, whether it was

solid viscera; it does this imperfectly in man. Experimentally, when the rent is not too large, the omentum seems to occlude it and prevent leakage from the intestine. In perforated appendicitis, for instance, while the omentum is present in a great number of cases at the seat of the perforation, peritonitis, due to leakage, nevertheless frequently occurs.

The usefulness of the omentum in inflammatory lesions of the abdomen depends on (a) its power to form adhesions which isolate and render innocuous toxic products; (b) to its power of absorbing and eliminating toxic products or destroying them by virtue of its phagocytic elements. But when contrasted with the sequelæ, intestinal obstruction, pain, etc., its beneficence is overbalanced. The chief functions of the omentum are those of any other mesentery, namely: (a) fixation of viscera; (b) vascular supply. When the omentum is found adherent to an intra-abdominal tumor the probabilities are that the mass is inflammatory, and not neoplastic. If the tumor is adherent to a neoplasm, the tumor invariably has undergone inflammatory changes. (Ovarian dermoids.) In exploratory gall-bladder operations it is well to remember that an "adhesion" between this viscus and the omentum does not necessarily mean inflammation. The adhesion may be a normal mesentery of the gall-bladder, contributed by the omentum. Care should be exercised, therefore, in the examination of the adhesion before it is unnecessarily separated, and before the gall-bladder is removed. The best method of preventing adhesions between abdominal incision and omentum consists in the application of a continuous peritoneal catgut suture. Areas of the abdominal cavity uncovered by peritoneum lead almost invariably to adhesion formation. The omentum is capable of absorbing large quantities of fluid and particles in suspension. Large particles are attached in a purely mechanical way. Too much should not be expected from grafts of the omentum. A detached piece of omentum rapidly becomes necrotic, and is useless. Only intact portions of the omentum produce serviceable adhesions.

72. **Operative Method for Exstrophy of the Bladder.**—The operation devised by Werelius is done in two stages: The first stage consists of the formation of an artificial bladder (urodenum). The operative field (left abdominal side), after ordinary preparations, is painted with tincture of iodin and protected from the area of exstrophy by placing an adhesive strap obliquely across the lower abdomen and over a towel covered with oiled silk, which is then turned over the exposed bladder, completely excluding it from the operative field. The patient is then tilted over on his right side to allow the urine to flow away from the working area, and also to get the small gut out of the way. An oblique incision is then made in the left inguinal region, much the same as for appendectomy on the opposite side. The sigmoid is delivered through the wound and divided about 7 inches above the rectosigmoidal junction and the proximal end anastomosed to the upper part of the rectum, leaving a future artificial bladder about 6 inches long. The abdomen is closed in the usual manner without drain. In the second stage, a flap of bladder containing the ureters is dissected and all of the bladder mucosa is cut away. Through a median abdominal incision the intestinal pouch is exposed and partly delivered through the wound and clamped with rubber-covered forceps. The clamped gut is opened into the lumen. The bladder flap is then approximated to the intestinal opening and sewed to the edge, through and through with linen. The opposite edge is sewed with a Connell stitch, so that, when finished, the gut somewhat overlaps the bladder flap. If the intestinal tissue is abundant, serosa may be drawn over so as to cover the flap completely. The abdomen is closed, with gauze drain *in situ*.

89. **Cirrhosis of the Liver.**—A venous hum, accompanied sometimes by a well-marked thrill, has been detected by Thayer in the epigastrium in some instances of hepatic cirrhosis. He says that the thrill and murmur may be appreciable: (a) directly over the extensive cutaneous varicosities, or (b) in instances where there is little or no external evidence of venous engorgement. In most of the cases in which an epigastric venous hum has been heard in cirrhosis, in the absence of cutaneous varicosities, the sound has been audible best about the umbilicus and along the median line in the epigastrium—in other words, along the course of the round ligament. In a few of these instances it has been found that the incompletely closed umbilical vein has become greatly dilated as a result of increased portal pressure. In others, a large dilated vein has been found in the round ligament running alongside of the obliterated umbilical vessel—doubtless a dilatation of a small para-umbilical vein. Thayer points out that these murmurs should be distinguished from the slight venous hum sometimes heard in the anemic just above and to the right of the umbilicus, over the inferior vena cava—murmurs which may be brought out by pressure in thin individuals. These murmurs are said to disappear in some cases with pressure on one or another femoral vein (Friedreich). A venous hum has been described in Traube's space and in the left side of the epigastrium in the angle between the large liver and spleen in cirrhosis (v. Jacksch, 1899) and in splenic enlargement (Piazza-Martini, 1898), which may arise in a varicose splenic vein. A well-marked thrill and an intense venous hum may be heard in hepatic cirrhosis over a limited area in the epigastric notch, in the immediate neighborhood of the xyphoid cartilage, at a point so far above the lower border of the enlarged liver that it cannot depend on currents in a varicose umbilical or para-umbilical vein. Such murmurs may, in some instances, arise in varicose coronary veins (v. Jacksch), while in others, as those observed by Catti and the author, the seat of origin is probably in anastomoses between the roots of the internal mammary and the inferior deep epigastric vessels, very possibly to the entrance into these latter veins of an enlarged para-umbilical-xyphoid vein of Braume.

91. **Traumatic Diabetes in Children.**—Two cases of diabetes are reported by Abt and Strouse in which the glycosuria first came to light after the patients had suffered injury. The first child sustained injuries to the leg and abdomen in an automobile accident; the second child fell from a second-story window, striking on his head. In addition to the possible traumatic origin of these cases, there is an added interest in that both patients continue robust and in good health in spite of the daily elimination of a considerable quantity of sugar. This is in contrast to the text-book descriptions of cases of diabetes in children, which usually relate that in young individuals, more particularly children, diabetes runs a rapidly unfavorable course. It is also of interest to note the effect of the v. Noorden oatmeal diet on sugar elimination and acid retention. The ordinary clinical study of the first case showed an apparent anomaly in the production of an acidosis by the v. Noorden gruel. This point was especially

investigated in the second case. For certain periods the patient was allowed a somewhat restricted diet, containing gluten bread, supposedly starch-free, but actually, on analysis in the laboratory, yielding 32.5 per cent. starch. For the first ten days the food was not measured accurately enough to allow complete figures of food value to be stated; but from March 21 to April 9, each article was carefully weighed and its value computed, mainly from Atwater's tables, partly from analyses made in the laboratory. Very little restriction, except of carbohydrate, was enjoined during the period of liberal diet, and at all times the patient was allowed to roam about the wards, under surveillance, to prevent secret taking of food or loss of urine. The absolute reduction in sugar output as soon as the patient was put on v. Noorden's gruel was striking, and was in perfect accordance with the claims of v. Noorden and the experiences of other workers. In both cases, however, acetone, which was practically never present during the periods of glycosuria, invariably appeared after administration of the oatmeal gruel.

Clinically associated with this were symptoms suggesting acidosis, such as nausea, rapid pulse and headache; the ferric chlorid reaction, however, generally was absent. Since it is very unusual for acidosis to follow the use of v. Noorden's gruel, it was thought that the quantitative determination of the nitrogen and ammonia output might explain the apparent deviation from the usual reported reaction. There was a relative increase of ammonia each time the v. Noorden diet was given, but the nitrogen excretion always fell markedly because of a low protein intake. The figures representing total ammonia vary considerably and are not in agreement with the percentage curve. In fact, during the periods when the ammonia was 10 per cent. of the total nitrogen, the actual ammonia output was lower than it was at any other time during the period of observation. It is probable that the increased ratio is due to the low total nitrogen excretion, corresponding to the sudden diminution in the nitrogen intake. But the figures at the first and last v. Noorden period show an absolute increase of ammonia. After three days of the gruel, 4 grams of ammonia, or 22 per cent. of the total nitrogen, were excreted in the urine, and with the reduction of the glycosuria after the gruel later, the actual as well as the relative ammonia elimination was increased. The use of fresh vegetables and the v. Noorden gruel resulted in raising strikingly the patient's tolerance for carbohydrates and in reducing considerably the degree of acidosis. These two cases of traumatic diabetes ran a milder course than is usually seen in diabetes in children, but otherwise in their urinary and therapeutic reaction they did not differ essentially from cases of diabetes of non-traumatic origin.

92. **Biot's Breathing.**—During the past two years, in the course of a more or less systematic graphic study of pathologic types of breathing, Conner has encountered typical examples of Biot's type of respiration seven times. In six instances it occurred in the course of meningitis; in the seventh, it was found in a child suffering from some intracranial complication of suppurative mastoiditis, the nature of which could not be determined. The characteristic features of this form of respiratory arrhythmia may be stated as follows: (1) periods of apnea, which vary in length and occur at irregular intervals; (2) constant irregularity in rhythm, and in the force of the individual respirations; (3) frequent occurrence of deep sighs; (4) great uniformity of the expiratory level, a point noted by Conner and one not previously described.

94. **Interrelation of Organs of Internal Secretion.**—Hoskins says that most of the available evidence indicates that the thyroid stimulates the adrenals. Hypothyroidism causes hypertrophy in the pituitary, probably due to a vicarious assumption of thyroid function. It is fairly well demonstrated that there is a relation between the thyroid and the gonads, which are probably stimulated to normal activity by the former. The frequent association of abnormal conditions in the thyroid and thymus points toward a relationship between them, but definite evidence on the point is meager and conflicting. The theory that the thyroid inhibits the pancreas is probable, but more data are needed.

96. **Congenital Syphilis of the Heart.**—It is stated by Warthin, that gumma of the heart is rare in congenital syphilis, but that congenital syphilis of the heart, in the form of a localized or diffuse interstitial myocarditis, is most probably not rare. The new criterion is the demonstration of the *Spirochæta pallida* in the proliferating interstitial tissues of the heart wall. Adler could base his diagnosis of syphilis only on the endarteritis. Warthin has shown that the same type of interstitial myocarditis in the absence of coronary endarteritis is syphilitic, by demonstrating that these light-staining patches of proliferating stroma represent localized colonies of the spirochete and that the organism occurs in such patches in extraordinary numbers. The myocarditis described by Coupland, Hektoen and Le Count, Warthin believes to be of the same type, sufficiently localized in the cases reported by the last two writers to be visible to the naked eye and to be interpreted as gummata. In all cases of cardiac disturbances in children, congenital syphilis should be carefully considered as a possible factor.

Warthin's series of cases also show that it can be a cause of asphyxia neonatorum and unexplained sudden death in infancy. Under such circumstances, the possibility of congenital cardiac syphilis must be borne in mind and a thorough microscopic study of the heart carried out. The same thing is true of cases of non-development, infantilism, chronic valvular lesions in children and young adults, etc. For all of these conditions an etiology of congenital syphilis of the heart is possible, and the diagnostic criterion is the demonstration of fibroblastic areas in the heart wall containing colonies of spirochetes. Congenital syphilis of the heart occurs most frequently in the form of a diffuse interstitial myocarditis due to the presence of the *Spirochæta pallida* in large numbers, without ordinarily producing characteristic macroscopic changes so that the absence or presence of congenital cardiac syphilis can be told only by a thorough microscopic examination of the heart wall.

107. **Thrombokinase.**—Believing that it would be interesting to take animal extracts and use them locally, Strong employed Batelli's method which consisted in extracting the tissue of the lung of the sheep with distilled water or salt solution, and then precipitating it with a very weak percentage of acetic acid; then centrifuging the precipitate, evaporating and adding alcohol to preserve it. He found that alcohol did not render it perfectly sterile, so he tried 1 per cent. thymol, and evaporated the precipitate at a low temperature with the electric fan, and then added an equal bulk of 1 per cent. thymol in alcohol. In order to determine if there was anything specific in the powder, whether it was

different from any other foreign body in its effect on coagulation. Strong conducted a number of experiments noting the coagulation time with rabbit blood, and found that he could secure coagulation within forty-five seconds. He also used various powders, and found that sometimes these delayed clotting rather than hastening it, and sometimes they had no special effect. So, apparently, here was something specific in its action. It did not lose its power when heated dry, but when it was moistened and heated with a very moderate degree of heat, 60 C. for thirty minutes, it became inactive. On that demonstration Strong based his claim of there being a ferment body in this preparation. No clinical data on the use of this substance, which Strong calls "thrombokinase," are available, although it has been used by a number of clinicians.

112. Papilloma of the Larynx.—The following are the most interesting features of the case: It gives the natural progress of papilloma of the larynx beginning in infancy and continuing undisturbed by treatment up to the age of 47 years. The very unusual fungoid appearance of the growth (so far as Carter can discover no case like it has been recorded), and the subsequent history are also of interest, whether the patient develops a speaking voice and whether there is a recurrence of the growth. The latter, Carter believes is unlikely, as the growths were thoroughly removed and the patient has passed that age when there is a tendency to warty developments. The larynx before operation was almost completely blocked by fungoid papillomatous masses, the largest of which, attached to the left side of the larynx, acted like a ball-valve and caused almost complete obstruction on inspiration. The edematous condition of the surrounding tissues gave the impression of an active inflammatory process.

It is also worthy of mention that these extensive growths were all removed endolaryngeally. Carter regards the endolaryngeal operation as the ideal one in these cases, and can scarcely conceive of a case of papilloma of the larynx justifying thyrotomy. In operating, he prefers the snare to any other instrument for the reason that the growth can be removed more accurately, more thoroughly and with far less injury to the surrounding healthy parts. The latter is most important, for it is the common observation of laryngologists that recurrences are more apt to spring from those portions of the larynx that have been injured during the operative procedures than from the bases of the primary growths.

113. Quinsy in an Adult.—The quinsy in Prowse's case was bilateral, the abscesses extending far down the neck, practically enveloping the whole larynx laterally and anteriorly; the characteristic doughy swelling was evident before the section was begun, and there had been no rupture of the abscess into the air-passages. Death had been preceded by violent struggling for air and clutching at the throat, and the post mortem disclosed that death had been due to edema of the glottis, hastened, no doubt, by the exertion of walking, and that an intubation and laryngotomy would probably have saved the patient's life.

120 *Management of Children Predisposed to Nervousness. L. F. Barker, Baltimore.

120. Management of Nervous Children.—Barker insists emphatically that in any case nervous children should not be sent to school too early: preferably they should start a year or even several years later than the normal child. And in the schools they should never be pushed ahead too fast; competition is dangerous for the nervous child. The mistaken ambition of parents who desire their children to head the class is often responsible for serious injury to health. Sleeplessness is always a danger signal. In children it is frequently due to indigestion or to mental overstrain; occasionally to premature sexual excitations. If insomnia appears, and especially if it persists, the parents should consult a physician.

121. The Fasciculus Occipito-Frontalis.—In his anatomic researches on the brain Rhein found that there is in the upper levels on the right side a band of degenerated fibers more intense in the posterior wall of the lateral ventricle, which can be traced to hemorrhage in the levels below which destroys the tapetum to a certain extent. This band of degenerated fibers is continuous with a faint line of unstained or poorly stained white matter which at the uppermost levels surrounds the lateral ventricle, leaving a band of well-stained white matter between it and the ventricular wall. Forward and in the outer wall of the ventricle, this band corresponds to the position of the fasciculus occipito-frontalis as described by Marburg's atlas recently published. At a little lower level, this band cannot be traced all around the ventricle but is present still to a marked degree in the posterior wall of the lateral ventricle. These areas of degeneration, Rhein believes, may probably be interpreted as being fibers of the fasciculus occipito-frontalis which have been pushed to the side by the distention of the ventricle. At levels still lower the fasciculus occipito-frontalis is undoubtedly degenerated, and the unstained bundle of fibers can be traced in the corpus callosum as far as the median line, and when the same level on the left side is studied this can be followed into the fasciculus occipito-frontalis on this side. What appears to be degeneration can be traced into the splenium on the right side, but what the fate of these fibers on the opposite side is cannot be determined. Probably, though, they extend into the tapetum of the left side, as in one section the tapetum was degenerated and degenerated fibers could be seen in the splenium. There is little doubt in Rhein's mind that the degeneration of the fasciculus occipito-frontalis can be traced directly to the degenerated tapetum on the right side. That the degeneration in the corpus callosum is continuous with the degeneration in the fasciculus occipito-frontalis seems more than probable. This finding is uniform in a great many sections, and in comparison with sections from another brain recently studied, it appears to be undoubtedly abnormal. These findings support the views of those who claim that the tapetum is a part of a long association bundle connecting the frontal and occipital lobes. Whether the tapetum is made up exclusively of fibers from the fasciculus occipito-frontalis or in part from the corpus callosum cannot be definitely stated from the findings in this case, in spite of the fact, that degenerated fibers could be found in the splenium directly traceable to the original hemorrhagic focus, since the white matter of the occipital and temporal lobes was implicated as well. In Rhein's opinion, it seems probable that there is a long association bundle corresponding in position to the *"faisceau occipito-frontal"* described by Dejerine, of which the tapetum is a part, and which sends some fibers across the knee of the corpus callosum to the fasciculus occipito-frontalis of the opposite side.

3. **Chronic Subcutaneous Fibrosis.**—It is held by Stockman that chronic inflammation of the subcutaneous connective tissue is a very common affection. It is secondary to various acute and chronic infections. The implication of the small peripheral nerves in the chronic inflammatory process gives rise to sensations of aching, stiffness, numbness, fatigue, etc. When persons already stout, or who afterward become so, are affected, the fat tends to form larger or smaller masses round the hypertrophied connective tissue. These masses are often very painful on pressure owing to the nerve twigs being in a condition of interstitial neuritis. The fatty masses are deposited mostly in the ordinary situations of fat accumulation. The abdomen, flanks, hips, thighs, shoulders and upper arms are in general the parts most affected, but sometimes fat is also deposited in the face, forearms, hands, legs and feet, either diffusely through the hypertrophied fibrous tissue or in lobules. When there is a large amount of subcutaneous fat the secretion of sweat is interfered with, but in most cases the amount of perspiration is normal. The morbid anatomy is very simple. When excised portions of subcutaneous tissue are examined microscopically, the fibrous tissue, the peripheral nerves and the blood-vessels are found to be in a condition of chronic interstitial inflammation; the fat cells are normal in appearance. In some cases, the fibrous tissue is much denser than in others. The condition is analogous to fibrosis of the lung, liver, kidney or ligaments, and, as, in these cases, is due to chronic local irritation from the toxins of germs or more definite chemical bodies. The most suitable name to apply to the condition, Stockman says, is probably the pathologic one of "chronic subcutaneous fibrosis." He reports five cases.

4. **Leukocytic Extract in Infective Processes.**—Alexander thinks that a new view may be taken of these extracts. They may in themselves be bactericidal and bacteriolytic to some slight degree, and they may contain natural anti-endotoxins. But they seem to act chiefly as leukocytic stimulants, inducing a huge outflow of cells, whose function is to protect the body from infection.

7. **Eucalyptus Oil Poisoning.**—A boy of 6, who had occasionally been in the habit of getting a drop or two of eucalyptus oil on sugar, was given by mistake a teaspoonful. This was about 6 o'clock one evening. About 8 he had his usual light supper, and within two hours thereafter abdominal pain and severe vomiting set in. The vomiting continued without cessation of any length and diarrhea soon became marked. By 11 o'clock the boy became drowsy, and when he was seen about this time by Foggie, he was semi-comatose. He was pale and collapsed, with a small but not very quick pulse. The muscles generally were flaccid. The pupils were medium in size and equal. The conjunctival reflex was not quite abolished. The tendon reflexes were present and were not exaggerated. There was no cough and the breathing was shallow. He could be roused by very vigorous slapping of the face, but each time he looked dazed. Every time he was wakened the nausea and vomiting set in. The vomited matter, which consisted of mucus and watery material, had a strong smell of eucalyptus oil. After two or three hours of external stimulation very much along the lines usually adopted for opium poisoning, the heavy comatose condition seemed to pass off, and the child was allowed to sleep. He slept well, and next morning, beyond being a little tired, was quite himself again. The breath had a smell of eucalyptus oil for three days. There was never any irritation of the urinary tract. In brief, the poison showed itself by gastro-intestinal irritation and cerebral paresis.

26 Recent Advances in Hematology. W. K. Hunter.
27 *Cases Resembling Atrophy of the Optic Nerves which Recovered Under Treatment. L. Buchanan.

25. **Hematoporphyrinuria Not Due to Drugs.**—The patient, an unmarried woman, aged 27, housekeeper by occupation, came under the observation of Munro and Borland on account of symptoms resembling those of a mild type of diabetes. One week after a very severe chilling received while sea bathing, she observed the "bright magenta" tint of the urine. Her general condition was not satisfactory; she frequently vomited and ever since the chill she had been compelled to rise several times each night to micturate. The depth of the color varied. After a large dose of salts, the urine might be less dark, and occasionally seemed to clear for two or three days, but it invariably resumed its reddish color. She suffered a good deal from thirst and dryness of the mouth, and recently lost weight somewhat, and has been troubled with boils of the axillæ. Two of four specimens of urine examined contained sugar.

27. Cases Resembling Atrophy of the Optic Nerves.—During the past six or eight years, Buchanan has seen a considerable number of patients who presented many symptoms of atrophy of the optic nerves, but who have, fortunately, recovered the visual power fully both as regards central and peripheral vision. All the patients have been males between 30 and 50 years of age, and all have been steady, healthy looking men, working in responsible positions. None of the patients exhibited the signs or symptoms of toxic amblyopia; none was addicted to the overuse of either alcohol or tobacco; and none complained of, or exhibited evidences of either digestive derangement, kidney disease, or syphilis. In each case the complaint was of slowly increasing defect of vision both for near and for distant work, without any head pain or other evidence to lead to a definite cause. There can be no doubt that the diminution of vision must have been of recent origin in several. The symptoms have been diminution of central vision—both form and, less markedly, color—and peripheral contraction of the visual field, generally symmetrical. The optic nerves presented the appearance of early atrophy, pallor and sharp outline, without diminution of the caliber of the central vessels. In none of the patients was there any evidence of nervous disorder, and the subsequent history of such of the patients as Buchanan has been able to watch for one, two, three or more years has proved that the disease was not due to advancing sclerosis of brain or spinal cord. Examination of the urine showed that there was no disease of the kidneys, and careful inquiry failed to show any point from which toxic influences could start. The treatment in all cases has been purely medicinal—either tincture of nux vomica or strychnin, combined with iodid of potassium, in doses which were moderate at first, but later increased to full. In general, no benefit was experienced until a month or two had elapsed, and then it was slow but steady for about a year. Treatment was kept up until the visual acuity and the field of vision ceased to improve. In general, no improvement or alteration of the appearance of the optic nerve was seen, the size, outline and hue remaining much as at first. No diminution of caliber of the vessels was seen in any case.

31 *Subcutaneous Emphysema in a New-Born Infant. H. Wilkins.

31. Subcutaneous Emphysema in a New-Born Infant.—Wilkins reports the case of a primipara, aged 33, who, after a prolonged labor in which delivery was affected by axis-traction forceps, gave birth to a male child on Sept. 22, 1910. Although the heart was working well, artificial respiration had to be employed for about twenty minutes as the infant at first refused to breathe, and a large quantity of liquor amnii was expressed from the mouth and nose. The following day acute edema developed over the head, thorax and scrotum. The bowels and urine were normal. On September 26, the child, which had been crying lustily for the last twenty-four hours, suddenly became silent. The edema was then being rapidly replaced by a subcutaneous emphysema over the front and back of the head and thorax. The child could swallow well, but had complete aphonia. The breathing was slightly stridulous. There was no cough. Hot fomentations were applied to the neck, the nostril and nasopharynx were sprayed with normal saline solution, and 3 ♏ doses of wine of ipecacuanha were given every two hours. At midnight the emphysema had increased, and there was considerable dyspnea. Râles and rhonchi were heard over both lungs, the respirations were 48, and the pulse was feeble. The infant was listless and showed no desire for food. Hot fomentations were then applied to the chest and back and 20 ♏ of brandy were given every hour, together with wine of ipecacuanha and syrup of tolu and squills. The following day, September 29, the child was better generally, and took its food well. The emphysema was less on October 1, the child could cry loudly and the emphysema has almost gone. Subsequent recovery was uneventful.

33 A Trip to India During the Plague Season. R. W. H. Jackson.
34 *A Case of Thrombosis of the Superior Mesenteric Vein. J. Burgess.

34. Thrombosis of the Superior Mesenteric Vein.—In addition to its rarity the interesting points in Burgess' case are: (1) the vagueness and mildness of the early symptoms; (2) the superimposition of a second group which completely masked the preceding; (3) the rapid course to its fatal termination in a few days from a condition of health. When first seen the man seemed in no way ill. The previous day he had suffered from diarrhea with griping pains in the abdomen. The former had ceased, but the pains had not altogether disappeared. He was a stout, florid man, aged 65. A year previously he had suffered from a similar attack, which had yielded to simple remedies. Burgess prescribed a carminative for him and saw no cause to apprehend any further trouble. Late in the evening, the pain, although not severe, was continuous, and he had passed no motion or flatus during the day; he had retched bile (sic) three times. At this time temperature was normal, pulse 112, very high tension, heart sounds were distinct; there was no murmur present. The pain was referred to the left hypochondrium. There was no tympanites, and, although suffering, he made light of his condition. The urine was high-colored, but contained neither albumin nor sugar. A symptom which puzzled Burgess was a hyperesthesia of the rectum. The next day the pain was less, otherwise the man was no better. Temperature was subnormal, and pulse was 120, wiry in character. There had been one attack of vomiting in the early morning. No motion of flatus had passed. There was absolutely no rigidity, tympanites, or pain on deep pressure of the abdomen. The symptoms present were the continuous pain (by no means severe), the quick pulse and the rectal tenderness. The vomiting occurred on such few occasions that Burgess does not feel justified in giving it prominence. Repeated turpentine enemas, opium and hot fomentations failed to give relief. Three days later, temperature was normal, pulse 120, respirations 24. The patient was semicomatose; he could be aroused to answer questions, but his replies were erratic. There was no paralysis; the pupils acted normally. There was no vomiting. The bowels had acted after an enema had been given. There was absence of rigidity of the abdominal muscles. No complaint now of pain. A blood-count was made with negative results as to leukocytosis. Like negative results attended a lumbar puncture. The urine, except showing a slight trace of bile, was normal. On the following day, a change for the better occurred, but temperature was 101 and pulse 120. Then the man became deeply comatose; his face was suffused, and the pupils were equally dilated. Breathing was stertorous, without any Cheyne-Stokes character. He was passing urine involuntarily, and his temperature was 103 F. He was restless, rolling from side to side, perspiring freely; and at times trying to get out of bed. There was no paralysis of any muscle group. The pulmonary signs were loud rhonchi over both lungs. The abdomen was very slightly, if at all, distended. The liver dulness was normal in position, there was no enlargement of the spleen; but, being a fat subject, a satisfactory examination was difficult. There was no rigidity of the muscles. The coma deepened, and the man died the following morning. At the necropsy the liver showed a marked grade of atrophic cirrhosis, the typical hob-nail, alcoholic variety, with thrombosis of the superior mesenteric vein, as high up as the junction with the splenic; two loops of small intestine were ecchymosed, partly gangrenous, were adherent to each other and to the mesentery of the sigmoid; there was no perforation of the bowel, and there were about 150 c.c. of free fluid in the peritoneum. Other findings, including the head, were negative.

41 *Reflex Calculous Anuria. H. Eliot.
42 *Aspiration Treatment of Chronic Urethritis. Bronner.
43 Anuria from Concrement in Single Kidney Cured by Catheterization of Ureter. (Anurie calculeuse dans un rein unique traitée et guérie par le cathéterisme urétéral.) André.

40. **Operations on the Kidney and Pregnancy Later.**—Hartmann reports normal pregnancy in eight women in whom a kidney had been incised or removed a year or more before. He has compiled sixteen other cases of the kind, and adding these to eighty-nine already published brings to 113 the number of cases on record in which an operation on the kidney was followed by pregnancy. In none could any influence be detected on the pregnancy from the fact of the preceding nephrotomy or nephrectomy. In thirty-five cases the operation was done during pregnancy, so that the latter is no contraindication for nephrectomy. He concludes from the data presented that marriage may be authorized in such cases, even if the operation had been done for renal tuberculosis, if the urine is sterile, as determined preferably by inoculation of animals. Pousson deduces similar conclusions from sixty-six cases he has compiled except that he insists on a careful study of the general health before authorizing marriage after nephrectomy, especially the functioning of the cardiovascular apparatus and liver and the anatomic and functional condition of the remaining kidney. Even with profound changes in the remaining kidney, with purulent urine, he has known nephrectomized patients to bear healthy children; but it would be taking too many chances to authorize marriage in such a case. In twenty-nine out of thirty-two patients in whom the nephrectomy had been done for tuberculosis, the pregnancy developed apparently normally, as also in nine of ten women operated on for lithiasis, and in all of the thirteen women in whom the operation had been for a suppurative process in the kidney.

41. **Reflex Anuria.**—Eliot remarks that a pathologic kidney is especially susceptible to reflex influences, and particularly organs in which there are concrements. He analyzes nineteen cases on record and reports one from his own experience. In the latter, the obstruction of the left ureter by a concrement induced total anuria. The concrement was dislodged and expelled by the simple expedient of distending the bladder, when the anuria at once subsided. Py Suner has demonstrated an antitoxic power in the kidney enabling it normally to neutralize toxic substances circulating in the blood. He has further demonstrated that uremic blood has an inhibiting action on the secretion of urine. When suffering from the presence of concrements, the antitoxic power naturally is enfeebled, while the uremic intoxication although possibly still latent may aid in inducing anuria.

42. **Aspiration in Treatment of Chronic Urethritis.**—Bronner introduces a perforated sound connected with a water jet vacuum pump and manometer, insuring a constant aspiration inside the urethra, maintained for ten or fifteen minutes at a time. The urethra is thus cleansed from all secretions and débris while the aspiration acts as a kind of massage of the walls and induces a healing local hyperemia. The results have been satisfactory, he reports, in over a dozen old chronic cases, and he thinks that the method deserves a wider trial.

January 18, No. 2, pp. 37-72

47 General Principles for Examination of a Sick Child. E. Périer and E. Gaujoux. Commenced in No. 1.

44. **Curable Forms of Acute Tuberculosis in Children.**—Aviragnet and Tixier declare that the discovery of tuberculous tracheobronchial glands is important both for diagnosis, prognosis and prophylaxis. With acute symptoms, this discovery clinches the diagnosis and after their subsidence shows persistence of a dangerous focus, while it often clears up the diagnosis in latent tuberculosis. All children with swollen glands in the mediastinum should be regarded and treated as tuberculosis suspects, and should be guarded with special care against whooping-cough and measles which seem to be particularly disastrous for the general evolution of tuberculosis. These infections seem to display a special predilection for the lymphatic system and for the glands in particular. If the tuberculosis in an old tuberculous patient does not flare up anew after these infections or influenza, this may be accepted as a sign that the process has definitely healed and that the patient need no longer be classed as tuberculous.

46. **Peritoneal Complications of Scarlet Fever.**—The prognosis of peritonitis seems to be favorable when it is a scarlet fever complication. In a case described by Touraine and Fenestre, a boy of 14 developed scarlet fever during convalescence after an operation for appendicitis and scarlatinal acute peritonitis developed, but all disturbances subsided as the exanthem disappeared. They analyze a few similar cases on record in which an exanthem seemed to have developed on the peritoneum and disappeared with the superficial eruption under medical measures only. This peritoneal syndrome differs completely from the secondary peritonitis which may develop a week or weeks later, and which has quite a different prognosis.

51 *Lavage and Massage-Lavage of the Colon. J. Baumann.

50. **Operative Treatment of Typhoid Perforation.**—Giordano says that he has been able to save only about half of the patients operated on for this condition, but that they would all have inevitably succumbed if he had not operated, and he advises prompt surgical treatment and close supervision afterward in every case of peritoneal complication of typhoid, occlusion or perforation. He adds that he will not say that no one dies now from peritonitis, since Murphy introduced proctoclysis, but he will assert that not so many die from it. A typical case of typhoid perforation is reported in detail.

51. **Massage-Lavage of the Colon.**—Baumann makes a rectal injection of about a pint of fluid, which is ejected at once. This is followed by a second injection of about a quart. The patient then reclines in the dorsal decubitus and the physician, at his left, massages the fluid up into the colon and spreads it around with gentle manipulations. After massaging against the normal current, he massages then with it, the superficial effleurage toward the anus starting the bowel content in its natural course and regulating peristalsis. This procedure should not be often repeated or the bowel may become accustomed to it, and it should always be done very gently, never hurting the patient.

58 *Infantile Scorbutus. E. Lust.
59 *Scarlet Fever in a Nursing Mother. B. Delmas.
60 *The Elbow Sign of Scarlet Fever. C. Pastia.

52. **Differentiation of Epidemic Poliomyelitis and Meningitis.**—Moussous reviews the difficulties encountered in distinguishing between cerebrospinal meningitis, epidemic paralysis, infantile paralysis and acute encephalitis, stating that only the

newer differential methods allow correct differentiation, examination of the cerebrospinal fluid, etc. The lack of these in the past has led to much confusion. He insists that the sequels of cerebrospinal meningitis should be studied anew on the basis of the most modern methods, as he is convinced that many evils have been attributed to it for which it is not responsible—this mistake being the natural result of its having been confounded with other diseases.

53. **Koplik's Spots.**—Biehler has examined 947 measles patients for the Koplik spots and extols their diagnostic importance in permitting recognition of the disease before any other signs become apparent. They were found the day before the eruption in 864 cases, two days before in forty-two and up to ten days before in one case.

54. **Perivascular Localization of Intestinal Tuberculosis.**—Péhu has been studying for years the localization of tuberculous lesions in the intestine and states that they always are found close to the blood-vessels. This proves, he is convinced, that these lesions are of blood-borne origin and that the tubercle bacilli must have gained access to the body by inhalation, finding their way then from the air passages into the blood and settling at points of lessened resistance. He adds that the rarity of primary intestinal lesions is another argument in favor of this view, and also the fact that notwithstanding the general practice of pasteurization, boiling or otherwise sterilizing the milk, tuberculosis has never been so frequent nor so deadly in young children as at present. The infant consultations and sterilized milk depots are only an indirect means of prophylaxis, as Comby has recently pointed out; they are useful mainly in detecting latent or masked tuberculosis in the family and thus permitting proper measures to prevent infection of the infant by inhalation.

55. **Serologic Diagnosis of Whooping-Cough.**—Delcourt extols the advantages of the complement-fixation test in revealing latent or masked cases of whooping-cough in children and adults. Epidemics are kept up by these unsuspected cases, and their discovery is naturally of great importance for prophylaxis.

56. See abstract in THE JOURNAL, Dec. 10, 1910, p. 2099.

58. **Infantile Scorbutus.**—Lust remarks that he had encountered only seventeen cases of infantile scorbutus during eight years of practice when six came under observation in the course of three months. The cases were all in well-to-do families.

59. **Scarlet Fever in Nursing Mothers.**—Delmas' patient developed typical scarlet fever while nursing her month-old babe. The disease ran the usual course without complications and the infant continued to nurse and thrive without contracting the disease. Scarlet fever is rare in infants less than a year old, and it is possible, he thinks, that the mother's milk confers a passive immunity on the child.

60. **The Elbow Sign of Scarlet Fever.**—Pastia gives two illustrations of the stripe or stripes across the bend of the elbow to which he has called attention as an early sign of scarlet fever. The linear eruption is first pink, then dark red or dregs of wine color, or like an ecchymosis, and it leaves a pigmented stripe for a time after recovery.

62 Sterilization and Desiccation of Medicinal Plants. E. Bourquelot.
63 Vaccination Against Typhoid. E. Delorme and A. Netter.

61. **Cholera During 1910.**—Chantemesse regards emigration as the most important factor in the spread of cholera nowadays. Recent experiences have shown that infection was spread by individuals who had left the endemic focus twenty-five or thirty days before, and their goods had been disinfected several times, and they themselves inspected by physicians at two or three different times in the interval. Thus all the provisions of the present maritime sanitary police had been fulfilled to the letter, and yet cholera developed among them. Epidemics and poverty are driving people to emigrate, and the poverty pilgrimages are as dangerous to the health of the world as the religious pilgrimages which have so long been the concern of the public health authorities, while the present international five-day supervision and other regulations are proving inadequate, he declares, to cope with present conditions.

Lyon Chirurgical, Lyons

February, V. No. 2, pp. 109-208

64 *Adomino-Perineal Technic for Removal of Cancer of Uterus and Rectum in Women. (De l'ablation en un seul bloc de la masse recto-utéro-annexielle et du tissu cellulaire périphérique comme méthode opératoire dans le cancer du rectum chez la femme.) Albertin.
65 *Idem. (De l'amputation abdomino-périnéale du rectum, avec hystérectomie concomitante.) Goullioud.
66 *Abdominal Hysterectomy in Treatment of Cancer of Uterus, Rectum and Colon. L. Tixier.
67 *Sigmoiditis and Cancer. X. Delore and L. Lambert.

64. **Cancer of the Uterus and Rectum.**—Albertin advises removing the uterus with the cancer mass in the rectum, all in one piece. He first opens the abdomen and detaches the whole mass, preserving in the pelvis the ureters and the bladder. The abdomen is then sutured and the cancer mass and the adherent genitals are removed through the perineal incision. This technic is for the cases in which partial resection is inadequate and an iliac anus is necessary.

65. **Id.**—Goullioud has operated in five cases of rectal cancer in women by amputating the rectum with concomitant hysterectomy. Two women survived for fifteen and sixteen months and the others are in good health after two and four years to date.

66. **Id.**—Tixier advocates preliminary abdominal hysterectomy which, he thinks, reduces the gravity of the operation. He describes two cases in which this technic was applied on women aged 33 and 58 and both are in good health at present, respectively six and nearly four years later.

67. **Sigmoiditis and Cancer.**—Delore and Lambert report three cases of apparent simple sigmoiditis in which operation showed a malignant tendency or a tuberculous stricture. The patients were a woman of 48 and two men, 60 and 69 years old. None survived the peritonitis for which the operation was done. Histologic examination alone permits the differentiation in dubious cases when there are suppurative complications. In one case there had been symptoms for nearly two years, in another for one year and in the third the syndrome of peritonitis and occlusion developed abruptly.

72 Congenital Absence of Peroneus Muscle. L Dieulafé.

70. **Cesarean Section.**—Kouwer states that in Holland obstetricians still prefer the classic technic and his own experience confirms its advantages. It has its drawbacks, but he is convinced that not one is suppressed by the extraperitoneal, suprasymphyseal technic while the latter exposes the woman to graver dangers than the classic method. He has done Cesarean section in sixty cases among 18,200 parturients, and he reviews this experience in detail, tabulating the various groups for comparison. The mortality for which he considers the operation responsible was only 1.72 per cent. although not all the patients were free from suspicion of infection. The chance of infection is increased by the longer duration of labor.

71. **Momburg-Belt Constriction to Arrest Obstetric Hemorrhage.**—Guéniot reviews eighteen articles that have been published on this subject and his own experience. In the majority of the cases the hemorrhage was arrested at once. The method produces disturbances in the circulation and arterial pressure but if the cardiovascular system is in good condition, he says, no harm results. It is better to refrain from this method in case of heart disease or arteriosclerosis, especially in surgical cases, but in obstetrics the method may prove a life-saving measure, especially in country practice and even

in well-equipped institutions. Some recommend that the Momburg tubing should be carried in every obstetrician's bag. The rubber tubing preferred is about the size of a finger, but ordinary gas tubing or the tube from a fountain syringe may be used. The technic was illustrated in THE JOURNAL, Oct. 30, 1909, p. 1519.

78 *Hemolytic Jaundice with Occasional Hemoglobinuria. A. A. H. van den Bergh.

76. **Protracted Fever in Infectious Diseases.**—Bernheim called attention in 1876 to cases in which the fever of an infectious disease persisted after subsidence of all other symptoms and, although apparently doing no harm, yet the temperature kept above normal for weeks, months or even years. The fever was generally noted in the evening, the temperature being normal the rest of the day. He has encountered the phenomenon with typhoid and paratyphoid. influenza, acute articular rheumatism, erysipelas, catarrhal pneumonia and pleurisy. The disease does not run itself out like the eruptive fevers and fibrinous pneumonia, but the fever-inducing microbes or their toxins evidently linger in the organism. The trouble is rather a tendency to relapses and recurrences than a steady febrile condition, as he shows by thirteen case-histories reported in detail. In one of bronchopneumonia all other symptoms had subsided by the forty-fifth day, but fever persisted to the eightieth day. In a case of right pleurisy all symptoms had disappeared by the twenty-seventh day, but the fever was evident until the one hundred and third day. The influence of influenza was evident in a few of the cases.

78. **Hemolytic Jaundice with Hemoglobinuric Crises.**—The patient in the case reported was a man of 47 who since 1899 has had recurring jaundice with occasional attacks of hemoglobinuria. Each attack is accompanied by more or less anemia, oppression in the cardiac region and pain in the hypogastrium, some of these symptoms persisting between the attacks to some extent. The blood findings are those of secondary anemia. The trouble seems to be an exceptional fragility of the man's blood-corpuscles in the presence of carbon dioxid at body temperature. This could be shown *in vitro.*

84 *Treatment of Eclampsia. H. Heinze.

84. **Treatment of Eclampsia.**—Heinze's method is: (1) Rapid artificial delivery without the cooperation of uterine contractions; vaginal hysterectomy or abdominal Cesarean section if cervix and os are not dilated; forceps and version if sufficiently dilated; (2) curetting the uterus if eclampsia persists after delivery, even if the placenta has apparently been removed; (3) decapsulation of the kidneys if the eclampsia still persists and there are signs of serious injury of the kidneys; (4) general measures, including venesection, proctoclysis, the Jaquet pack, diuretics, heart stimulants, artificial respiration and inhalation of oxygen. He gives the case-histories of three very severe cases in which treatment on these principles proved successful. In a fourth case this entire battery had not been brought to bear and the patient succumbed, which he thinks might have been prevented with a little more energetic treatment. Hall, Tatzke and Fellner have reported cases in which puerperal psychosis or eclampsia subsided after curetting.

86. **Sham Tuberculin Reaction in the Tuberculous.**—Weihrauch has tested the reaction in 212 tuberculous patients to a sham test injection of tuberculin. The instability of the heat center in the tuberculous was evidenced by the rise in temperature in 56, that is, in 26.4 per cent. after the slight trauma of the injection of mere water or the introduction of the needle without any injection; the reaction was more pronounced when aided by verbal suggestion by the physician. The rise in temperature was accompanied by general disturbances only in two cases, that is, in 0.9 per cent. The pseudoreaction may prove misleading in the clinic; the real criterion is the reaction in the tuberculous focus. There is no focal reaction after the sham injection and the temperature also drops more rapidly than after the real tuberculin injection. There did not seem to be any difference between the length of the interval before the temperature rose after the real and the sham injection except that a positive reaction was obtained between the twelfth and the twenty-fourth hours in eight patients with tuberculin and only in two so tardily with the sham tuberculin.

87. **The Serodiagnosis of Tuberculosis Not Practicable.**—This is the conclusion reached by Roepke after extensive experimental research on the possibility of transmitting to guinea-pigs the anaphylaxis possessed by tuberculous human beings.

91. **The Cardiovascular System in Pulmonary Tuberculosis.**—Fürbringer discusses the toxic influence on the heart and vessels of the tuberculous infection and the organic changes liable to result therefrom. Auscultation rarely shows normal conditions in the heart action. Accentuation of the second pulmonary sound is extremely frequent, he says, even with slight infiltration of the left, upper lobe, of which it may be the first sign in adults. The toxic influence of the tuberculous infection is felt mainly by the myocardium, and this permanent overirritability of the heart almost inevitably entails in time organic injury of the heart muscle and arteriosclerosis.

94. **Deceptive Lung Findings in Scoliosis.**—Neumann analyzes the percussion and auscultation findings liable to be encountered with curvature of the spine and mistaken for the results of tuberculous processes in the lungs. He cites some typical examples of various types of this scoliotic pseudotuberculosis and complications. In one case there was deformity of the chest plus acute bronchopneumonia. In another case the scoliosis was accompanied by a recent active tuberculous process in the lung, and in another with relics of an old healed process. Only a thorough knowledge of the findings to be expected in the chest with curvature of the spine will permit correct differentiation in such puzzling cases as these. He has found them comparatively frequent and, oftener than not, tuberculosis has been incorrectly diagnosed. In a typical case a high school graduate was rejected by a medical examiner on account of pronounced dulness over the back of the right apex, assumed to be a sign of a tuberculous process. The young man held himself straight, but closer examination

of the back showed that the left iliocostal muscle was abnormally prominent. A tendency to scoliosis was thus detected and the findings over the lungs proved to be those characteristic only of curvature of the spine. Such cases are frequently encountered, the patients passing through the hands of many physicians, none of them discovering the scoliosis responsible for the pseudotuberculosis findings. Many of the patients were regarded as holding themselves unusually straight; in some cases lordosis in the middle thoracic segment of the spine contributed *to the stiffly erect posture. The scoliosis in these puzzling cases* is too slight to attract attention unless especially sought for. One shoulder a little higher than the other, lordosis in the thoracic vertebræ or undue prominence of the sacrolumbal muscle on one side may be the only sign of the tendency to scoliosis. Neumann's experience has further shown, he asserts, that persons with kyphoscoliosis and mitral defects are exceptionally resistant to pulmonary tuberculosis. Among 1.767 cadavers only 59.5 per cent. were found free from tuberculosis, while of 120 cadavers with mitral defects, 77.6 per cent. were free from tuberculosis and 73.4 per cent. of 49 kyphoscoliotic cadavers. Among the typical findings with scoliosis Neumann mentions contralateral apical dulness, that is, on one side in front and on the other side in the back; dulness over the apex at the rear with dulness over the base on the other side. If dulness is noted over a lung corresponding to the extent of the scoliosis, this cannot be accepted as an indication of tuberculosis. Another sign of the pseudotuberculosis is the lesser movability of the base of the lung on the side opposite the convexity of the curvature of the upper thoracic vertebræ. This sign was constant in his cases. With light percussion the lung was found two or three finger-breadths above that of the other side and the margin of the lung did not share in the excursions of the other side.

95. **The "Tuberculin Titer" Quantitative Test.**—THE JOURNAL, May 15, 1909, page 1634, described the method devised *by Ellermann and Erlandsen to test the hypersusceptibility of the organism to tuberculin* by a graduated cutaneous tuberculin test with varying concentrations of the tuberculin. Erlandsen states that further experience has confirmed the simplicity and reliability of the method. He has worked out a set of tables for exact mathematical recording of the individual findings. All that is necessary to know is the average diameter of the four papules that follow inoculation with the four concentrations (0.5, 2, 8 and 32 per cent.), and the average of the differences between the diameters of the papules. The table shows at a glance the corresponding titer within a range of titers from 25 to 5.846, thus enabling instructive comparison of cases, and estimation of the individual conditions.

97. Practically the same article was abstracted in THE JOURNAL, Jan. 28, 1911, page 314.

Vaccine Diagnosis.—Reiter reiterates that every infected organism for a certain period is in a condition of specific allergy, during which it reacts in a specific manner to renewed introduction of the substance inducing the allergy. If this premise is correct, administration of the allergy-inducing substance is a valuable means of differentiation of the infection in question by the specific reaction that follows. Vaccines prepared according to Wright's method answer the desired purpose, and he has found it possible to confirm by this means the diagnosis of streptococcus, gonococcus, pneumococcus and other infections—the specific vaccine induced in every instance a strictly specific biologic reaction. Reiter would like to see this allergic reaction used in other diseases besides tuberculosis and anthrax to which now it is generally confined. It may render good service in other occult infections; the polyvalent vaccines are proving most useful. The serologic determination of the negative phase will further perfect our knowledge of differential biologic reactions in general and the vaccine diagnosis is liable to prove exceptionally valuable in differentiating extra-uterine pregnancy, appendicitis, oophoritis, cystitis, etc. The reaction should not be regarded as more than an adjuvant diagnostic measure; only a focal reaction, he adds, is positive proof of a specific affection. The vaccines are best tested on absolutely healthy individuals; no harm can result, he declares, with the minute dosage required.

100. **Rachitis as a Causal Factor in Curvature of the Spine.** Böhm gives illustrations of a number of cases of curvature of the spine to show that it can be traced in an unsuspectedly large proportion of cases to rachitis in early infancy. Treatment should begin earlier than has been the rule hitherto; physicians should search for the tendency to curvature of the spine in young children with signs of rachitis, and institute treatment in time to prevent irreparable injury. He decries the assumption that faulty postures and school work can induce curvature of a healthy spine. The Roentgen rays, etc., always reveal some anatomic basis for the deformity.

101. **Couching of the Lens for Cataract.**—Levinsohn thinks that under certain urgent indications this operation deserves reinstatement. Such indications are hemophilia and restless mania preventing a cutting operation on the eye. He has recently done reclination in two elderly insane women, and the results, he reports, were highly gratifying; there has been no tendency to glaucoma or other complication during the four and six months to date.

112. **Abnormal Gastric Secretion.**—Tabora reviews recent progress in treatment of secretory stomach disturbances, especially hyperchlorhydria. It used to be supposed that sodium bicarbonate taken after a meal was the most effectual means of combating hyperacidity, but the laboratory has shown that secretion in the stomach is checked by taking the alkali fasting—checked both directly in the stomach and by reflex action from the passage of the alkali into the intestine. The more rapidly the alkali passes into the intestine, the sooner this inhibition occurs, and consequently the best results are obtained when the alkali is ingested fasting. Treatment of hyperacidity, therefore, is by having the patient take half

an hour before each meal a little alkali, and Tabora prefers for this a mixture of 20 parts magnesium usta, 10 parts sodium citrate and 5 parts sodium or magnesium sulphate. A four or six weeks' course of this generally suffices. He has abandoned the use of the bicarbonate as it is liable to induce discomfort and the carbonic acid evolved is a stimulant to further secretion. Sodium and magnesium sulphate have also an inhibiting action on gastric secretion in addition to their valuable laxative powers. The diet should be regulated to postpone as late as possible the production of free acid in the stomach, and this is best realized with an albumin-fat diet: he restricts the diet to albumin and fat more exclusively the severer the secretory disturbances but otherwise prefers a mixed diet. The articles of food should be in such a form as to expose the largest surface to the action of the gastric juice. It is better consequently to have the food in a soft mashed or finely chopped form than to have the patient chew it long, as mastication in itself induces by reflex action secretion in the stomach. Meat is less stimulating in this respect when boiled. The meals should be reduced in number but copious. If the alkali treatment does not cure, a course of oil, 3 tablespoonfuls daily between meals, for several weeks, and eventually a little belladonna may be advisable. With chronic hypersecretion atropin is indicated in case the above measures fail, and the patients should be taught how to use the stomach tube themselves to siphon out the stomach content in case of much pain, especially before retiring at night. He adds that in this case as in all other affections the patient must not be forgotten in treating the stomach trouble, the blood, the mental poise, etc., must be considered. When the stomach trouble is an insufficiency of the secreting powers, rinsing out the fasting stomach with a dilute saline solution is useful, as also administration of hydrochloric acid. The latter not only aids in digestion but starts pancreas functioning, checks putrefaction in the intestines and by reflex action opens the pylorus.

113. **Blotting-Paper Test for Free Acid in Stomach Content.**—Holmgren has discovered that when a dilute solution of hydrochloric acid is dropped on blotting paper, as the fluid spreads by capillary attraction the water spreads farther and fastest while the acid only spreads to a limited distance around the center of the spot where it was deposited. The proportion between the percentage of acid and the proportional extent to which the acid spreads is a constant figure. From these premises he has worked out a simple quantitative test for determination of the free hydrochloric acid in the gastric juice. He applies with a pipette to a square of blotting paper a series of dots, 1 mm. apart, of a 1 per cent. aqueous solution of Congo red. He then deposits a small quantity of stomach content or solution of hydrochloric acid on one of the dots. The fluid spreads but the color reaction is obtained only with a certain number of the dots, those beyond not giving the reaction. By comparing the number of reacting dots with those beyond this zone but reached by the spreading moisture, we have the percentage of free acid in the fluid examined.

121. **Surgery of the Lungs.**—Solieri, of Siena, Italy, reports six cases in which an operation was done on the lung for abscess or gangrene, with recovery in all but one case in which the lesions were multiple and the patient a feeble young child. One patient was a man of 54 with a large post-pneumonia gangrenous process in the right lower lobe. The cavity was the size of a man's fist and the man collapsed as it was evacuated under local anesthesia and hovered between life and death for several days; the lips of the wound became gangrenous. Cautious cleansing with potassium permanganate and hydrogen dioxid gradually conquered this tendency and the patient left the hospital in good condition by the end of the month. The lung was entered from the rear in all the cases. Echinococcus cysts in the lungs promise better results after operative treatment, Solieri says, than any other surgical pulmonary affections.

122. **Improved Technic for Gastrostomy.**—Lofaro gives an illustrated description of his technic for making a permanent and continent opening into the stomach. [The main points were given in THE JOURNAL, Jan. 7, 1911, page 78.] He compares it with the various technics in vogue and extols its superior advantages. He has done the operation on eight large dogs and watched its ultimate outcome; complete and permanent continence was obtained in every case, the gastrostomy showing no change in any case during the months since, and his experiments on cadavers indicate that the same results can be counted on in human beings.

129. Practically the same article appeared in *Archives of Pediatrics*, June, 1910.

130. **Familial Mortality in Children.**—Stolte gives the details in respect to 100 families in which from two to ten children died before reaching the age of six, or still larger numbers died under the age of fourteen. In one family five children died about the end of the third month with diarrhea, although breast-fed and well tended. They were all "nervous" children and a neuropathic tendency seemed to prevail in the children of most of these families. The children in each family succumbed with apparently the same syndrome. Knowledge of such occurrences suggests antisyphilitic treatment of the parents in case of another pregnancy, if syphilis is suspected. When there is an unusual susceptibility to infections, general measures are useful in prophylaxis, but the physician is practically powerless in the cases where degeneracy is responsible for the lack of vitality.

139 *Injection of Gelatin for Functional Test of Bone Marrow. (Funktionsprüfung des Knochenmarks am Menschen mittels Gelatininjektionen.) A. v. Decastello and A. Krjukoff.

132. **Serous Meningitis of Posterior Cranial Fossa.**—The patient in Bing's case was a man of 27, previously healthy, who developed symptoms suggesting compression of the cerebellum and adjacent organs, commencing with weakness of the legs, and gradually increasing during the year until the patient was in constant dread of falling. He also felt dizzy in walking, sitting and reclining except when he reclined on the left side. Occasionally he vomited without preceding nausea. There was no actual headache but a sensation of oppression at the base of the skull. Numbness in the left hand was another symptom, and during the last few weeks there had been some impairment of vision and hearing. The appetite was good, sleep restless, bowel functioning defective, and there was left facial paralysis, but the eye reflexes were unmodified. On the diagnosis of tumor in the left cranial fossa—possibly serous meningitis—the focus was exposed and a cystic ac-

cumulation of fluid found in the posterior fossa, adhesions walling it in perfectly. As the adhesions were divided the fluid escaped and all trouble was at an end, the patient promptly recovering and the symptoms gradually subsiding. Six months later some of the symptoms returned to a slight extent but under potassium iodid they partially subsided anew and the cure was finally completed by substituting for the iodid. tincture of nux vomica. and pushing the dose rapidly to 40 drops a day. Improvement kept pace with it, the patient soon being freed from all symptoms. There was no history of trauma or syphilis in this case but the patient had had at one time a bilateral middle ear affection which might have been responsible for the development of the adhesions. The experience with this case testifies, Bing thinks, in favor of operative treatment at once without wasting time on lumbar puncture which could not possibly have done any good as there was *no* apparent communication between the cyst and the spinal fluid, while there is always a possibility of serious damage from lumbar puncture with any tumor in the brain. The case further teaches, he declares, the inadvisability of wasting precious time with antisyphilitic measures; an old syphilitic may have a non-specific tumor in his brain. In a case recently reported by Oppenheim he had diagnosed a tumor in the cerebellopontine angle and advised immediate operation, but as the Wassermann reaction was positive, although there was no history or sign of syphilis, a course of mercurial treatment was instituted and transient benefit was realized; soon, however, recurring severe symptoms brought the patient to the operating table and a fibroma as large as a hen's egg was easily shelled out of the angle. The patient died five days later of cardiac paralysis.

138. **Relation Between Civilization and Mental Disease.**—Tamburini cites historical data to show that mental disease was common among ancient and historical peoples and is common among the less civilized at the present day. The progress of civilization has eradicated the epidemic forms of mental disease, while the greater attention and care now paid to the insane has apparently increased the proportion of the mentally unsound, but he is convinced that this increase is only apparent. Civilization is now confronted with the task of eradicating the causes which breed mental disease, and he pleads for concerted international action, collecting and comparing data and teaching physical and moral hygiene—science, practical pedagogics and legislation all working toward this end.

139. **Gelatin Test of Bone-Marrow Functioning.**—Subcutaneous injection of a little gelatin is followed by marked hyperleukocytosis if the bone marrow is capable of responding to stimuli, as Decastello and Krjukoff found in tests of forty-two patients. The findings are important both for diagnosis and prognosis in certain circumstances.

Monatsschrift für Geburtshülfe und Gynäkologie, Berlin

149 Tuberculosis of the Female Urinary Apparatus. S. Mirabeau.
150 Chronic Intermittent Hydronephrosis in Women. S. Mirabeau.

142. **Puerperal Inversion of the Uterus.**—Pachner ascribes the inversion to relaxation of the muscular wall of the uterus. or of its lower segment. This view is sustained by the recurrence of the inversion at different deliveries, the peculiar thinness of the uterine wall in such cases, and the fact among others that inversion occurs more frequently at the first delivery and with younger women.

146. **Variations in Weight of New-Born Infants.**—In this communication from the Heidelberg Maternity, Heidemann states that he has made a practice during the last four years of having the infants nursed at intervals of four hours, that is, allowing only five feedings in twenty-four hours. This gives both mother and infant a chance to rest better, and systematic weighing of the children showed that they thrived unusually well under this arrangement. The nipples were less liable to crack with these long intervals, and working women found them much more convenient as the infant grew older.

Monatsschrift für Kinderheilkunde, Leipsic

IX, No. 10, pp. 549-592

151 *Influenzal Meningitis. G. Simon.
152 *Cardiospasm in Infants. C. Beck.
153 *Scarlatinal Thyroiditis. J. Bauer.

151. **Influenzal Meningitis.**—Simon reports two cases in previously healthy infants about eight months old. After a week of cough and fever, suppurative meningitis developed and influenza bacilli were found in the spinal fluid and pus in the cerebral ventricles, joints or middle ear. The primary focus was in the lung in one case and in a joint in another. He tabulates the details of forty-one somewhat similar cases he has found in the literature; thirty-three of the patients were under the age of 2 and 90 per cent. under 9. Only 10 per cent. recovered, including one woman of 33, two children about 8, and two infants, 9 and 14 months old respectively.

152. **Cardiospasm in Infants.**—Beck reports two cases in young infants causing uncontrollable vomiting; at first milk poured into the stomach through a tube was not vomited in one case. Later the cardia became impassible in both and the children were fed by the rectum for a time. Then under a little tincture of opium, feeding by the mouth was gradually resumed and there was no further trouble, the infants rapidly recuperating.

153. **Scarlatinal Thyroiditis.**—In Bauer's three cases there had been no tendency to goiter but the thyroid increased in size during the course of scarlet fever. It returned completely to normal size in one boy of 13 by the thirtieth day, but in another boy, traces of the swelling were still perceptible on the sixty-sixth day, as also in the third patient, a young woman, on the forty-third day. The thyroiditis in this case was evidently one of the primary manifestations. The scarlet fever had been of a mild type, with no other complications, in all.

162 Testing Vision in Examining Chauffeurs. (Das Sehorgan des Automobilführers.) G. Freytag.

156. **The Tourniquet Sign of Scarlet Fever.**—Leede has found that a slightly constricting band applied to the upper arm causes petechial bleedings below in case of the existence of scarlet fever. He has been applying this tourniquet sign in cases of suspected scarlet fever and obtained a positive response in all but 1 of the 200 patients tested; the single exception being a very fat girl, while a positive response was obtained only in one of the control cases—a syphilitic woman who proved to be free from scarlet fever. Nothing like the specific petechial spots in the bend of the elbow could be obtained in any other disease except that there was a slight tendency in this line in measles. In some cases the sign was positive the first day and the findings grew gradually less pronounced as the disease subsided, but it was still evident by the end of six weeks in some, and with hemorrhagic nephritis the sign was still positive by the fifteenth week.

The most convenient method of applying the constriction was with the Riva-Rocci cuff; the petechiæ developed in from five to twenty minutes. [Compare with Abstract 47 in THE JOURNAL, Feb. 18, 1911, page 545.]

159. **Gastric Fever.**—Scheglmann during the last two summers in his rural practice has encountered a number of cases of what can only be styled gastric fever. The last epidemic embraced 140 cases; after three days of fever at 39.5 or 40 C. (about 103 and 104 F.) the fever gradually declined and by the end of two weeks the patients had entirely recovered. The onset was stormy, with a chill and intense persisting frontal headache, with vomiting during the first two or three days; the patients also complained of oppression in the chest, pain in the stomach and all the limbs and extreme prostration. When they were able to get up they staggered, and the digestive organs were extremely sensitive so that the slightest indiscretion in diet during the second week brought on the whole syndrome again. No complications were observed, the kidneys appearing to be intact. He regards influenza as excluded on account of the total absence of catarrhal symptoms, the upper air passages persisting normal throughout, and there being no sacral pain. But the main argument against the diagnosis of influenza is the fact that other members of the family were not affected. An epidemic of influenza in the summer is also a rarity. No one seemed to be affected except harvest workers. The agglutination test for typhoid and paratyphoid was always negative.

165 Corporal Proportions of Cretins. A. Flinker.
166 Streptothrix Disease in Man. G. Gjorjevic.
167 Quarantine Studies. E. Wiener.

163. **Non-Destructive Action of Placenta Serum on Human Cancer Cells.**—The results of the research reported by Kraus and von Graff supplement the recent findings by others that under certain circumstances the human blood-serum loses the property of destroying carcinoma cells. Normal serum dissolves human and mouse cancer cells, while the serum of persons with cancer has lost this property, and Kraus and von Graff announce that the serum from the umbilical cord behaves in this respect like the serum from cancer patients. The blood-serum of pregnant women nearing term has the same property in a lesser degree. These facts seem to indicate that it must be the placenta which is responsible for the abnormal behavior of the pregnancy serum in respect to cancer cells and that the chemistry of metabolism is evidently involved in the phenomenon.

Zeitschrift für Urologie, Berlin

168 *Atony of Bladder Without Obstruction or Signs of Organic Nervous Disturbances. J. W. Thomson Walker.
169 Simple Pyonephrosis. (Zur Kasuistik der geschlossenen Pyonephrosen.) E. Meyer.
170 Case of Addison's Disease in Connection with Urogenital Tuberculosis. A. Werner.

168. **Atony of the Bladder Without Obstruction or Organic Nervous Disease.**—Walker reports nine cases in which nothing could be found to explain the insufficient expulsive power of the bladder. The age of the patients ranged from 22 to 59; two had had syphilis, four gonorrhea. The disturbance had come on slowly and gradually in all the cases, and in only one had there been acute retention at any time. The bladder was chronically dilated in four cases, but evacuation was finally complete, while in the others there was from 100 to 300 gm. of residual urine. In every case the bladder showed pronounced trabeculæ, but they were distributed differently from those observed in cases of obstruction, the side walls and apex being mostly involved. He regards the trabeculæ as secondary to the atrophy, and cites two additional cases in which the atony had progressed until the catheter had to be used constantly. He has been able to find only a few similar cases on record; he cites the details of Albarran and Nogues' cases in men of 27 and 28.

Zentralblatt für Chirurgie, Leipsic

February 11, XXXVIII, No. 6, pp. 185-224

171 *Modified Vein Anesthesia. A. Brüning.
172 *Plastic Closure of Fistulas Opening Out of Internal Organs. Abrashanoff.
173 *Chronic Catarrh of Breast. (Chronischer Katarrh der weiblichen Brustdrüse.) W. Mintz.

171. **Modified Technic for Vein Anesthesia.**—Brüning avoids the drawbacks of expulsion of blood from the entire limb—bloodlessness is an imperative condition for the success of vein anesthesia—by restricting the induced anemia to a comparatively narrow segment of the limb. This is accomplished by raising the limb for a time to expel the blood by force of gravity; then a constricting band is applied between the lesion and the trunk. Commencing at this band, the blood is expelled toward the trunk as by the ordinary technic, and then a second constricting band is applied above. By this means it is possible to obtain a bloodless zone of from 10 to 15 cm. wide between the lesion and the trunk, and here the anesthetic is injected to deaden the nerve trunks innervating the field of operation below. By the modification described, both constricting bands are applied above the field of operation leaving the lesion undisturbed until ready to operate. [The technic for vein anesthesia was described in THE JOURNAL, May 1, 1909, page 1466.]

172. **Fascia Plug for Fistulas.**—Abrashanoff cuts a strip of fascia, twists it around and pushes it down to the bottom of the fistula, holding it in place with a few sutures. It speedily grows to the freshened walls of the fistula and the spaces left are soon filled with regenerating tissues. He has applied the method in three cases with ideal results to date, over nine months in one case. The theoretical objections that might be made to the procedure do not seem to materialize in practice.

173. **Chronic Catarrh of Mammary Gland.**—Mintz applies this term for want of a better to a chronic secretion of yellow serum from one breast, persisting for from months up to several years, in the eight cases of the kind which he has encountered in the last six years at Moscow in women 30 years old and upward. The interval since the last pregnancy was nine or more years. Some had nursed and others had not nursed their last child. No subjective symptoms or appreciable changes in the breast could be discovered in six cases. In the seventh a carcinoma developed finally in the breast affected. In the eighth case an adenoma developed as the abnormal secretion became apparent, but the secretion persisted after removal of the tumor, and a superficial mastitis developed the sixth year. In the fifth year another adenoma developed in the other breast. He declares that the anomaly has nothing to do with Paget's disease of the nipple. In one case the secretion had persisted for two years, when it ceased after a course of potassium iodid, and there has been no recurrence during the three years to date. The secretion did not seem to have any connection with menstruation or the menopause. In the woman with carcinoma the secretion became hemorrhagic after three years as the tumor developed. He is inclined to explain the trouble as transudation from connective tissue accompanying a desquamating process in the acini, but he has not been able to examine a specimen anatomically. The affection has certain points in common with chronic cystic mastitis, of which he has encountered a special form, the mammary gland being studded with cysts with connective tissue walls, as he found in an operative case. He described this type in 1899, the subepithelial proliferation of connective tissue causing the casting off of the acinus epithelium, the latter forming, with the secretion from the granulations, the contents of the cysts.

177 Hypnosis. ("Suggestionsnarkose und Hypnose.") A. Rieck

174. Allowing Patients to Get Up Early After Laparotomies and Deliveries.—Aichel reviews the cases on record in which thrombosis developed in patients allowed to get up on the second or third day and analyzes the circumstances to determine whether this was responsible for the fatal outcome which has been reported in six cases. His conclusions are that this is possible only for two of the cases, Fromme's and Scherer's, and closer analysis of these fails to demonstrate that thrombosis and embolism are more liable to occur when patients are allowed to leave the bed earlier. The method has the great advantage that when patients are allowed to get up earlier they are kept under closer supervision than formerly, and this goes a long way, he remarks, toward prevention of sudden fatalities in parturients and patients after operations. Scherer has stated in regard to his case that it was his impression that the outcome of the thrombosis might have been more favorable if the patient had stayed quietly in bed. but Aichel comments that although this may be true, it is impossible to prove it.

188 Study of Coagulation of Blood. (Il tempo di coagulazione del sangue. Sostanze coagulanti e decoagulanti.) C. Mantelli.

183. Wassermann Reaction in Malaria.—Valerio found a positive reaction in 40 per cent. of a number of cases of recent malaria, free from syphilis. In advanced malaria and in old cases in which no parasites could be found in the blood the reaction was negative.

187. Improved Technic for the Wassermann Reaction.—Ferrannini writes from the medical clinic of the university of Naples, in charge of Professor Rummo, to state that it is possible to use in fixation of complement the blood of eels. Eel serum has long been known to have remarkable hemolytic powers. It was with the serum of eels that the well-known work on hemolysins and antihemolysins was done by Camus, Gley and Kossel in 1898 and Tchistowitch in 1899. The eel serum thus provides the hemolytic amboceptor for the fixation of complement test. From an eel weighing 200 gm., by cutting off its tail, enough blood can be obtained to yield 2 or 3 c.c. of serum after centrifugation or spontaneous clotting. This serum is especially hemolytic for rabbit red corpuscles. He has been making extensive comparative tests with the original Wassermann technic and with the eel serum used in place of the prepared hemolytic serum from rabbits—which it takes three or four weeks to obtain by repeated treatment of the rabbit. The findings were parallel in the long series of parallel tests and he thinks that as eels are readily procured and the serum does not lose its hemolytic property for some time after death, this modification of the technic will prove a welcome simplification.

189. Spondylarthritis.—Hedenius gives the details of seventeen cases of spondylarthritis. his analysis convincing him that there are two well-defined forms of arthritis of the spine which have frequently been confused in the past. The first is of an infectious-toxic nature generally but it can be likewise induced by trauma, severe or slight but often repeated. This form, which he calls ankylopoetic or adhesive spondylarthritis, usually attacks individuals in early middle age. The primary lesion is the ankylosis of the vertebræ as described by Bechterew, Strümpell, Marie and others. The other form, deforming spondylarthritis, has been described for centuries. It is not of infectious origin, so far as known to date is not accompanied by fever, and in most cases is localized in the lower segments of the spine. The trouble is generally stationary and displays little tendency to spread upward. Ankylosis of the spinal articulations is not the primary but a secondary phenomenon in this type; the pathologic process is often symptomless. Of course transitional forms may be frequently observed.

THE AUTONOMIC MANIFESTATION AND PERIPHERAL CONTROL OF PAIN ORIGINATING IN THE UTERUS AND ADNEXA[*]

CHARLES A. L. REED, A.M., M.D.
Professor of Clinical Gynecology in the University of Cincinnati, and Gynecological Surgeon to the Hospitals
CINCINNATI

GENERALITIES RELATIVE TO THE AUTONOMIC NERVOUS PHENOMENA

The word "autonomic" as applied to the manifestations of pain of visceral origin, signifies the expression of that pain in some superficial muscle or muscles rather than in the viscus in which it has its initial causation. The phenomena clearly imply the existence and coöperation of three distinct factors, namely:

1. Some more or less profound disturbances, functional or organic, of certain of the viscera.
2. The transmission of a painful impulse, thus originated, over or through what Head[1] has designated as the autonomic nervous system.
3. The registration of that impulse and its expression as pain in the muscle or muscles to which the respective external or peripheral autonomic filaments (muscle nerves) are distributed.

It is through this mechanism and by the coöperation of these factors, according not only to Head,[1] but to Ross[2] and Mackenzie[3] that the phenomenon of muscular rigidity occurs autonomically, for example, over an inflamed appendix vermiformis or over an impacted gall-bladder, or over the seat of an intussusception.

Through this same mechanism in each of the instances given, and for manifest reasons, the intensity of the pain and of the muscular rigidity are relative each to the other, while both are relative to the intensity of the causative change in the viscera.

The peripheral control of pain thus originating and thus manifesting itself implies either one of two hypotheses. The first is that if an algetic impulse can be telegraphed, as it were, from viscus to muscle, it would seem possible to telegraph an analgetic impulse back over the same wires, i. e., from muscle to viscus. The second hypothesis is that if the functions of the external autonomic filaments can be inhibited the algetic impulse cannot reach the muscles and must consequently fail of expression as pain.

Whether an algetic impulse originating in a given viscus *per se*, or whether, after transmission through the autonomic nerve filaments, it is expressed exclusively in or through its corresponding muscles, is a theoretical problem, the solution of which is quite apart from my present purpose.

AUTONOMIC AND OTHER NERVOUS RELATIONS OF THE UTERUS AND ADNEXA

The application of these general principles to conditions originating within the pelvis necessarily involves at least a brief consideration of the autonomic relations of the intrapelvic organs.

I find that the more convenient way to present this subject is to divide the genital organs into three zones, viz.:

1. The first or upper genital zone, consisting of the fundus of the uterus, the Fallopian tubes and the ovaries. To this zone are supplied:

A. Sympathetic branches from the plexus hypogastricus through the plexus arteriæ ovaricæ in the broad ligaments.
B. Sensory branches from the twelfth dorsal and from the first and second lumbar nerves.
C. Autonomic filaments afferent from the zone indicated to the spinal centers.

These filaments occur coincidently with the sympathetic and reach the spinal cord through the communicating branches in the lower dorsal and upper lumbar regions. Their terminal distributions are to the intertransversæ and to the quadratus lumborum and to the two psoas muscles.

2. The second or middle genital zone, consisting of the cervix uteri, to which are supplied:

A. Sympathetic branches from the lower ganglia.
B. Sensory branches from the second, third and fourth sacral nerves.
C. Autonomic filaments efferent from the cervix to the spinal centers through (a), the communicating branches of the sympathetic, (b), the second, third and fourth sacral, distributed to the two glutei muscles, to the quadratus femoris, the coccygeus, and the levator ani muscles.

3. The third or lower genital zone, consisting of the external genitalia including the vagina, is not considered in this connection.

THE RELATION OF AUTONOMIC NERVOUS PHENOMENA TO THE DIAGNOSIS OF INTRAPELVIC CONDITIONS

The nervous connections of the uterus and adnexa just given, taken in connection with the autonomic function as outlined by Head,[1] have an obviously important relation to diagnosis. Familiar phenomena of pain have a more definite meaning when interpreted in the light of these fact

---

[*] Read before the Fifth International Periodical Congress of Obstetrics and Gynecology, St. Petersburg, Russia, Sept. 22-28, 1910.

[2] Ross, James: Brain, 1888, x, 333.

[3] Mackenzie, James: Brain, 1893, xxi, 321.

I have been able in this way to associate pain in the costo-iliac interval and in areas representing the distribution of the posterior ramus of the twelfth dorsal nerve with conditions in the upper genital zone as follows, viz., (a) a small submucous nodule in the fundus of the uterus, (b) adhesions of the fundus uteri in the cul-de-sac of Douglas, (c) fixation (hysteropexy) of the fundus uteri to the abdominal wall (an operation never done by myself), (d) premenstrual engorgement of the uterus and ovaries. (e) cirrhosis with follicular degeneration of the ovaries, (f) distention of occluded Fallopian tubes, and (g) ectopic pregnancy.

I have likewise been able to demonstrate the relationship of pain in the ileogluteal area, supplied by the posterior rami of the second, third and fourth sacral nerves, with conditions in the middle genital zone, chief among which are the following, viz., (a) painful cicatrix of the cervix, (b) cervical erosion, (c) intramural myomata of the cervix and (d) cystic Nabothian follicles.

INTRAPELVIC CONDITIONS CAUSING AUTONOMIC MANIFESTATIONS OF PAIN

From the observations just recorded and from a general survey of the subject I am impressed with the probability that, in the majority of instances, more or less definite autonomic manifestations of pain will be found in conditions as follows, viz.:

1. In the uterus: malformations; certain new growths, both hyperplastic and inflammatory; certain premenstrual congestions; mechanical occlusions; displacements; infections.
2. In the Fallopian tubes: infections; occlusions with distensions; ectopic pregnancy.
3. In the ovaries: displacements; pressure from superimposed viscera; infections; tunicæ adventitiæ; adhesions; follicular degenerations; dermoids.
4. In the cervix: cicatrices; erosions; infections; distortions; neoplasms.
5. In pregnancy, complicated with neoplasms or neurasthenia or both.
6. In parturition, in which, ordinarily, the autonomic manifestations of pain shift from the upper to the lower (superficial autonomic) zones coincidently with the progress of the labor.

THE PERIPHERAL CONTROL OF AUTONOMIC PAIN OF INTRAPELVIC ORIGIN

If, from what I have already presented, we are to assume that pain originating in the uterus or adnexa is not pain until it is registered in the form of tonic contraction of the autonomically associated muscle or muscles, it would seem that inhibition of the autonomic function of the respective muscle or muscles would inhibit the manifestation of the pain. I have, in fact, successfully reduced this postulate to practice in a sufficient number of instances to convince me of its general tenability. It is accomplished, in brief, by deep analgetic injections into the substance of the affected muscles themselves. Whether the results depend on the analgetic agent or agents used in these injections, or on the water used, or whether both elements are of importance may will be taken up by the experimental pharmacologist.

I wish here to record, however, that, something like forty years ago the late Prof. C. G. Comegys of Cincinnati successfully inaugurated the practice of treating lumbago by injections of distilled water into the substance of the quadratus lumborum muscle. The practice is yet kept up with uniform success by my colleague, Prof. F W. Langdon[4] of the University of Cincinnati with whom, in these cases, aquapuncture is a matter of routine in his wards. In later years, following the introduction of cocain and its congeries of analgetic agents, and especially since the excellent work of Schleich[5] some fifteen years ago, there has been a tendency to rely on the injection of these agents rather than on the infiltration of water for the inhibition of nervous and muscular irritability.

It would seem, however, that in such conditions as lumbago, as shown by Langdon,[4] and in sciatica, as shown by Lange,[6] Sicard,[7] Hecht[8] and other neurologists, there is an increasing tendency to recognize the water as the relatively more important analgetic element of the solution. The three last-named authors are inclined to the use of water in the form of normal salt solution because of its assumed greater isotonicity. Then, too, we must recognize that another and a chief object that they have in using perineural infiltration of large quantities of water in sciatica is mechanically to break up inflammatory connections between the nerve and adjacent structures. Langdon insists, however, that it seems plausible to him "that distilled water would be effective and probably in smaller quantity since the 'affinity' of the nerve tissues (containing salts) would be greater, perhaps, for pure water"—a consideration which offers a rational explanation of his success in the treatment of lumbago by aquapuncture. But without going into this aspect of the subject, and without assuming for a moment that either lumbago or sciatica is autonomic in cause or character—although the former may be—both of these conditions present the phenomenon of muscular irritability and, in that particular, become important criteria for the control of muscular irritability from whatever cause it may occur.

THE RÔLE OF THE AUTONOMIC NERVES IN THE TREATMENT OF VISCERAL PAIN

It seemed to me,[9] after some study of this question, that if the autonomic nerves conveyed an irritating impulse from affected viscera to the surface, those nerves might be employed for telegraphing a corrective impulse back from the surface to the affected viscera. In other words, if, as Nothnagel and Lennander[10] insist, visceral pain is really pain manifested chiefly in the phenomenon of muscular hyperalgesia, why would not the inhibition of the muscular hyperalgesia inhibit in turn the visceral pain? Acting on this theory I promptly had an opportunity to put it to test. I had done a gastro-enterostomy to control pain and rigidity—epigastric hyperalgesia—following which I had applied heat to relax the muscles and given morphin with which to benumb the sensorium. Thirty-six hours of this treatment had failed to bring relief and the patient was crying to be reanesthetized. I therefore injected into the belly of the rectus abdominis muscles at several points on either side of the incision a solution of cocain and morphin in the form of a Schleich solution. Within twenty minutes the patient dropped into a comfortable sleep and from that time on had no recurrence of epigastric hyperalgesia. The pain following hysterectomies, oophorectomies, and other uncomfortable operations on the uterus and adnexa have been similarly relieved by deep muscular injections into the hyperalgetic areas. In a number of cases I have had entirely satisfactory results from the use of the cocain alone, and latterly with novocain, thus showing that it is sufficient to overcome what I look on as entirely normal but none the less painful muscular irritability, and to do so without hypnotics addressed to the general consciousness. Even in some instances, as in a case of a firm intra-uterine pack following a curettage, in which the superficial hyperalgesias were also present, the inhibition of the muscular irritability within the involved superficial areas was followed also by cessation of the pain referred by the patient to the uterus. From this experience, interpreted in the light of the facts which I have presented, I arrive at the object that I had in preparing this paper, and that was to emphasize, by brief summary, the treatment of various pains of visceral origin.

TREATMENT OF POST-OPERATIVE, PARTURIENT AND OTHER PAIN OF VISCERAL ORIGIN

1. Visceral pain, so far as the abdomen, pelvis and thorax are concerned, is expressed chiefly but not exclusively in the autonomic algetic areas of the protective walls covering the respective viscera, such algetic areas corresponding in extent with the peripheral distribution of the autonomic nerves coincidently with the peripheral distribution of the respective spinal nerves in the muscles and subserous connective tissue.

2. These distributions can generally be determined clinically by determining the area of partial hyperalgesia.

3. The pain itself, consisting chiefly of hyperexcitation of muscle irritability, can be partially and, as a rule, entirely, inhibited by inhibiting the muscle sensibility in the hyperalgetic areas.

4. The same principle applies to the peripheral control of pain originating in the parturient uterus, with the difference that the infiltration of succeeding muscle zones must be practiced with the corresponding advance of the delivery.

METHOD OF TREATMENT

My method of treatment, briefly stated, is as follows:

1. Have prepared a standard analgetic and local anesthetic mixture as follows:

	gm. or c.c.	
Morphin hydrochlorid	0	01
Novocain	0	04
Scopolamin	0	015
Normal salt solution	1	

This represents a single dose which, before administration. is further diluted with physiologic salt solution to permit of its distribution by numerous deep punctures with an ordinary hypodermatic needle into the hyperalgetic areas.

2. For analgesia, after thoroughly cleansing the integument, all of the mixture is injected into the muscular layer, several punctures being employed and care being taken to make them at points that approximately define the circumference of the hyperalgetic area. The analgetic effects will be realized within from five to ten minutes, and in consequence of the presence of the scopolamin, will be continued often from six to eight hours, while in some instances they will be permanent.

3. For local anesthesia, the same solution is used in the same way, with the exception that it is discharged into the subcutaneous connective tissue at points that approximately define the circumference of the area that it is desired to anesthetize. The sensibility will disappear in from five to eight minutes and will remain absent for a period varying from an hour to three hours.

4. The infiltration treatment practiced by Schleisinger, Hecht and others in sciatica involves the injection of large volumes of the solution, thus, (a) 10 to 20 c.c. of the normal salt solution reduced to zero (Centigrade); (b) 80 to 100 c.c. of normal salt solution at the temperature of the body; (c) 60 to 120 c.c. of beta-eucain solution at the temperature of the body. Langdon's method of treatment by pure aqueous infiltration involves the use of smaller volumes of fluid.

DISCLAIMER

Now that I have presented briefly this phase of the manifestation and control of visceral pain, and in view of the tendency to give a wider scope than is intended to a single idea, I wish, in conclusion, to make a few points clear. In the first place (1) the details of the autonomic phenomena are only beginning to be understood; (2) while I believe that these phenomena when once understood may be classed among the clinical constants, I do not believe that they can have a significance that will justify failure to consider all other diagnostic factors; (3) and I recognize the possibility and, under certain obvious circumstances, the desirability of temporary control of pain by the method I have indicated, I do not recognize the possibility that it can ever supplant the rational curative method which always implies the removal of the cause for the cure of the effect.

THE OPEN TREATMENT OF FRACTURES

S. D. VAN METER, M.D.
Visiting Surgeon to City and County Hospital
DENVER

It is admitted that a large proportion of fractures can be successfully treated by manual reduction and by the ordinary external appliances, designed to retain the fragments in place; but we are all familiar with the difficulty of securing and maintaining perfect reduction by these methods. Further, we know now that in many cases in which we have felt sure of having secured a satisfactory reduction, a subsequent radiograph has too frequently proved the error of our conclusions, and shaken our confidence in the time-honored tests of mensuration and palpation. Particularly is this true in fractures of the femur and humerus, in which we have to contend with a large amount of surrounding soft tissues, and especially when the fracture is oblique or comminuted. It is safe to venture the statement that in such cases an anatomic reduction is seldom, if ever, accomplished by the closed method; and if accomplished, it is next to the impossible to retain the fragments in position.

The recognition of these facts has led surgeons to resort to the apparently more radical procedure of the open treatment, which renders reduction comparatively simple and makes it possible to apply one of the many mechanical devices intended to retain the fragments in position. These devices are numerous, as the archives of surgery give evidence; but they may for practical consideration be divided into two classes, viz., those to be removed after repair of the fracture, and those to be left *in situ*.

The former have the apparent advantage of leaving no foreign body permanently imbedded in the tissues. The danger of trouble from leaving an aseptic metallic substance at the seat of the fracture has been greatly overestimated, however, and is not to be compared with

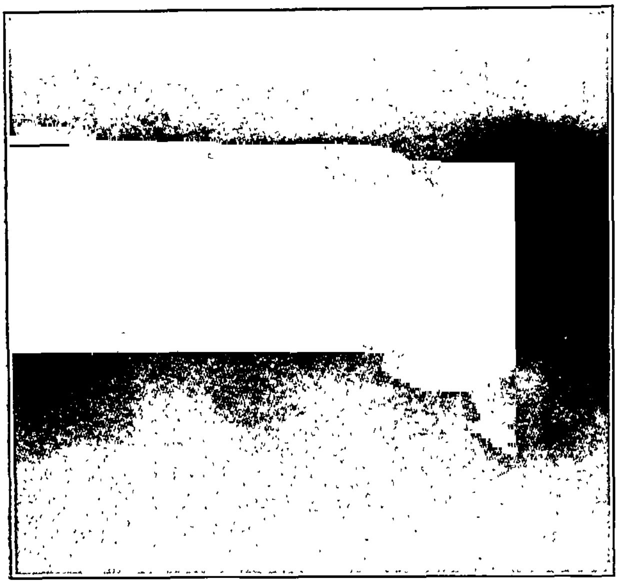

Fig. 5.—Fracture of left femur at middle of lower third with the usual backward displacement of the upper end of the lower fragment (Case 2). Reduction was thought to have been accomplished, but this conclusion was erroneous, as is shown by the radiograph.

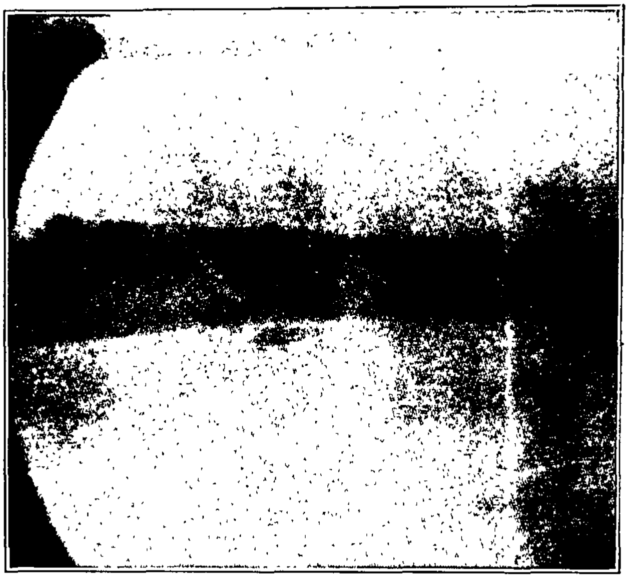

Fig. 6.—Reduction, by open operation and the use of the plate, of fracture shown in Figure 5.

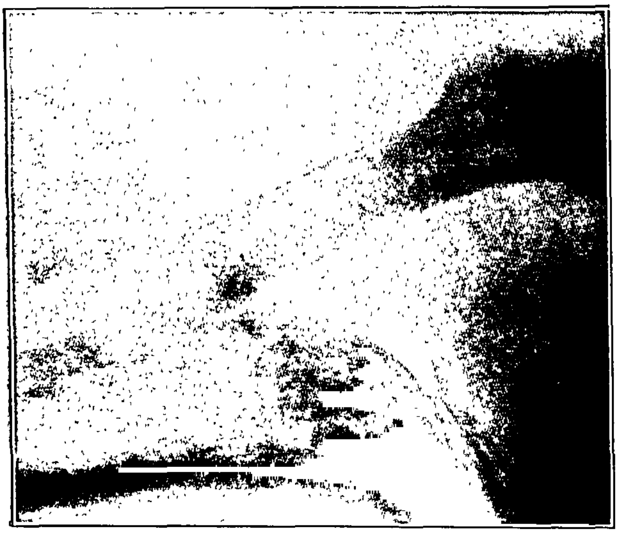

Fig. 7.—Fracture of the left humerus five inches above elbow involving the musculospiral groove, with marked forward displacement of the lower fragment (Case 3).

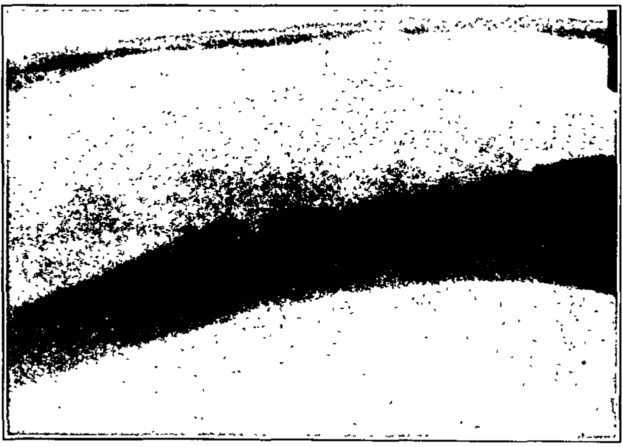

Fig. 8.—Reduction of the fracture shown in Figure 7, by the open method; alignment not perfect, but improved by splints and compresses.

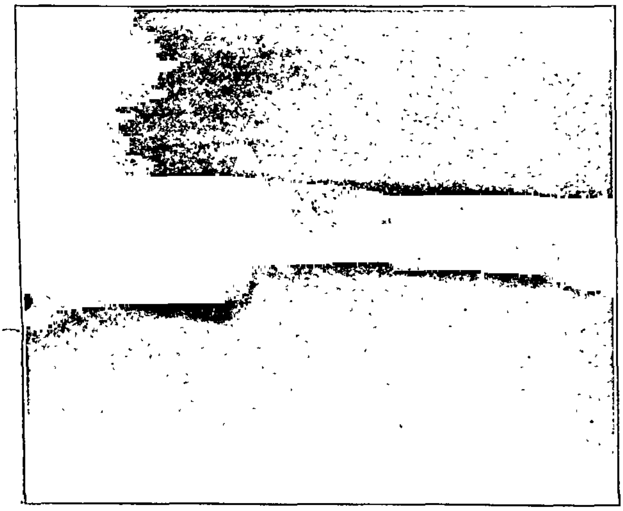

Fig. 9.—Fracture of upper third of left femur. Three unsuccessful attempts were made to reduce this fracture by the closed method (Case 4).

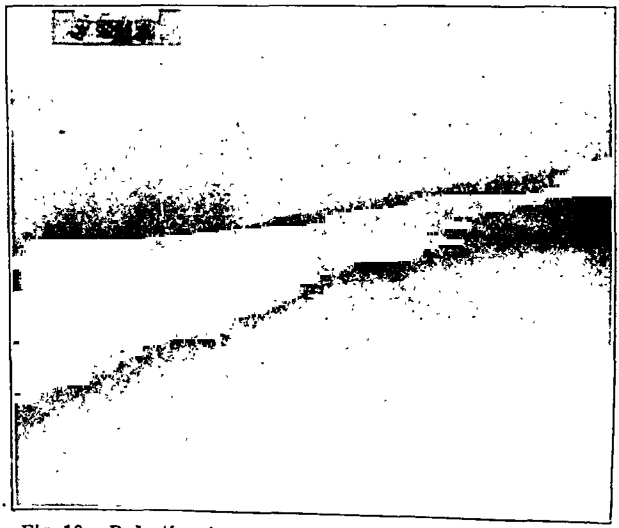

Fig. 10.—Reduction, by open method, of fracture shown in Figure 9, showing perfect alignment.

reduction. Reduction and alignment are shown by radiograph to be almost anatomic (Fig. 10). Convalescence was uneventful. Union occurred by first intention. There was no shortening.

Case 5.—Man, aged 32. Comminuted fracture of left humerus, with marked displacement (Fig. 11). There was a large hematoma extending into the axilla and on the chest anteriorly and posteriorly. Operation was done nine days after the injury. I considered it safe to wait until the tissues had gained some resistance. Several fragments of bone were removed at the operation. Their absence is well shown in the radiograph (Fig. 12). Convalescence was uneventful. Union by first intention took place. The patient undressed and dressed himself without assistance thirty-two days after the operation.

Case 6.—Boy, aged 18. Compound comminuted fracture of the left humerus, caused by passage of two wheels of a loaded coal wagon (7,450 pounds) over the member. Operation was performed two days after the injury. The patient traveled 150 miles from an inaccessible part of the state. The comminuted fragments were removed. The extensor muscles of the arm were severed by the crushing force of the wheels. The musculospiral nerve was tucked into the lower segment of the triceps. There was no infection of wound, which healed kindly as soon as the devitalized soft parts separated. Alignment is well shown in the radiograph (Fig. 13). There was some paresis of the flexors and extensors of the forearm, but at the time of the last report (nine weeks after the injury) power was rapidly returning.

1723 Tremont Place.

A METHOD OF TONSILLECTOMY BY MEANS OF A GUILLOTINE AND THE ALVEOLAR EMINENCE OF THE MANDIBLE

GREENFIELD SLUDER, M.D.
Clinical Professor for Diseases of the Nose and Throat, Medical Department of Washington University
ST. LOUIS

I wish to describe a method of tonsillectomy which, so far as I can learn, has not heretofore been described or used. The essential and distinctive feature of this method is the fact that it moves the tonsil completely out of its normal bed in the forward and upward direction and then utilizes one of the anatomic markings of the lower jaw as a vantage-point in putting it through the aperture of the guillotine. This anatomic marking is the well-defined eminence just above the mylohyoid line, produced by the last-formed molar tooth in its socket (Fig. 1, a, Fig. 2, I, a, Fig. 2, II, a), which is rendered even more prominent in the mouth by the tissues of the gum. In childhood the posterior, unformed molar as it lies imbedded in the alveolus helps to make the eminence (Fig. 2, II, a). This marking has not been given a name in any of the treatises on anatomy. I have taken the liberty of naming it "the alveolar eminence of the mandible," in order to facilitate the description of this procedure.

The instrument used (Fig. 3, I and 3, II) is a modification of what I have nearly always heard called the "Mackenzie guillotine"; but it occasionally has been called the "English guillotine" to distinguish it from the "Mathieu" or "French guillotine." Sir Morell Mackenzie,[1] however, relates that the instrument which nowadays bears his name is a modification of the one described by Dr. Physick[2] of Philadelphia in 1827, the difference being that he (Mackenzie) made the handle reversible, so that it could be applied to either side of the shaft. In this way he facilitated its use by surgeons who used the one hand for removing both tonsils. He also narrates that Dr. W. B. Fahnestock[3] of Lancaster, Pa., in 1832, first described the modification which consists of a circular aperture and a transfixing needle, with a ring knife to cut on the pull (the "French guillotine") and that Guersant[4] in 1864 changed the shape to an ellipse and at the suggestion of Velpeau added the elevating prongs. He furthermore states that the guillotine idea was first published

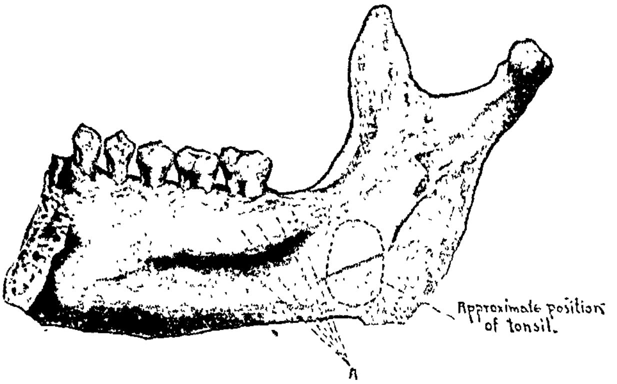

Fig. 1.—Inner surface of the right half of the mandible, showing the alveolar eminence, A, and its relation to the usual position of the tonsil.

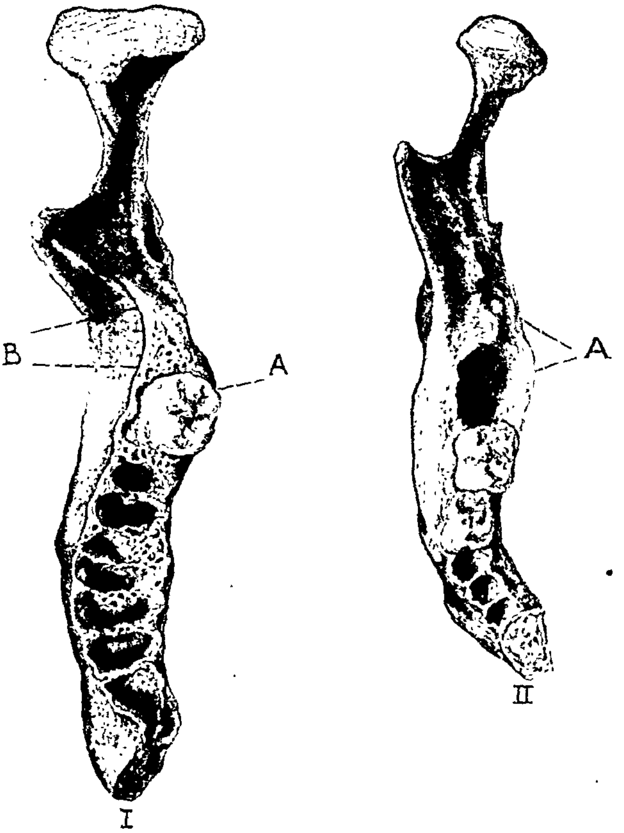

Fig. 2.—I. Right half of a mature mandible seen from above, showing alveolar eminence, A, with fully cut third molar and buccinator ridge B. II. Right half of young mandible seen from above, showing uncut third molar and the part it takes in the formation of the alveolar eminence A.

---

by Dr. Benjamin Bell[5] in 1783 in his description of the uvulatomes used in England in the latter part of the eighteenth century.

The guillotine which I use (Fig. 3, I and II) is therefore a modification of that of Dr. Physick, which consisted of a shaft of metal with a circular aperture at its distal end through which the tonsil was inserted, and cut through by a blade pushed across the aperture. I have altered the original model in order to accomplish two definite objects: (1) to get greater strength in the instrument; and (2), to increase the leverage employed in its use. These are attained (1), by doubling the thickness of the shaft; and (2), by shortening its length, and making the handle longer. I greatly prefer an elliptical aperture. The usual model of Dr. Physick's guillotine at present to be found in the instrument shops is the Mackenzie modification, which has a round aperture. In a few shops in the United States it has been made with an elliptical aperture the long axis of which is transverse to that of the shaft.

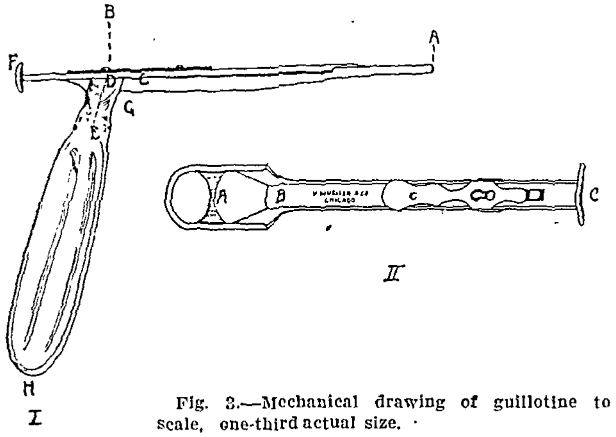

Fig. 3.—Mechanical drawing of guillotine to scale, one-third actual size.

In this operation a correct instrument is of very great importance. I believe it to be of far greater importance than is usually the case in surgical procedures. For this reason I feel that an accurate description ought to accompany its pictures.

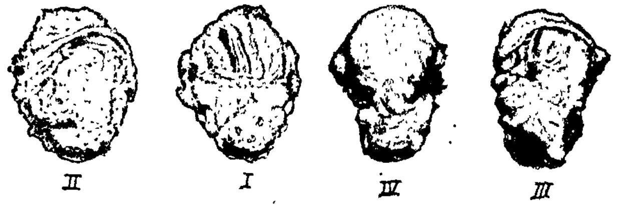

Fig. 4.—Tonsil removed from young adult: I, internal surface as it appears while still in the grasp of the guillotine, having the appearance of being turned inside out; II, same tonsil, external surface, with the capsule invaginated; III, internal surface after its parts have been replaced; IV, external surface after capsule has been replaced.

DESCRIPTION OF THE GUILLOTINE

(In the following use of terms I assume that the surgeon is holding the instrument, with its aperture from him). It is made entirely of metal. It measures 13. cm. from *A* to *B* (Fig. 3, I) which is from 2 to 4 cm. shorter than the models usually found for sale. The angle at which the shaft and handle join, *C, D, E,* is 115°. This is the most comfortable position for the handle in the surgeon's hand; and sacrifices almost none of its leverage. The handle should be large and rough, measuring 11.5 cm. from its free end *H* to its junction with the shaft *G*;and should be of a shape that is comfortable in the grasp, thus facilitating the use of strength. The shaft is thin, 3 mm., at its distal end where the aperture is cut; but is reinforced on the handle side, proximal to the aperture, by another piece of steel of the same or greater thickness, they being welded together and the handle attached to these. Special attention should be paid to details in order to make the instrument as strong as possible, such as putting a bolt through the full length of the handle in addition to its being welded to the shaft. Its strength should be so great that the shaft cannot be bent or the handle broken off by the power of an ordinary man. The blade is 2.5 mm. thick. Its proximal end, *F*, when closed (Fig. 3, I, is drawn with the blade open) should extend 2.5 cm. beyond the distal side of the handle at its attachment to the shaft *G*. Its cutting edge should be made dull for the reason that it will then readily follow in the connective tissue between the capsule of the tonsil and the constrictor of the pharynx on which it lies, whereas a sharp edge easily cuts through the tonsil or the constrictor. Less bleeding follows from the wound of a dull blade, which is an additional advantage. The edge should be made by grinding the blade 2.25 cm. *back* (Fig. 3, II, *A*, *B*), because by so thinning the cutting end of the blade the field of operation is made wider, as will be shown later. The proximal end of the blade is provided with a cross-bar *F*, which should be comfortable under the thumb so as to permit of great pressure without hurting the surgeon's hand. A ring may be substituted for the cross-bar and the surgeon's thumb inserted through it. The assumed advantage in this is that, in case he should not apply the instrument perfectly, he could readily withdraw the blade by means of his thumb without removing the instrument from its position, and immediately push it down again. This might be repeated until he had the tonsil properly through the aperture, with small loss of time; but he soon learns to do this with the cross-bar too, so at present my feeling is that this must be a matter of individual choice.

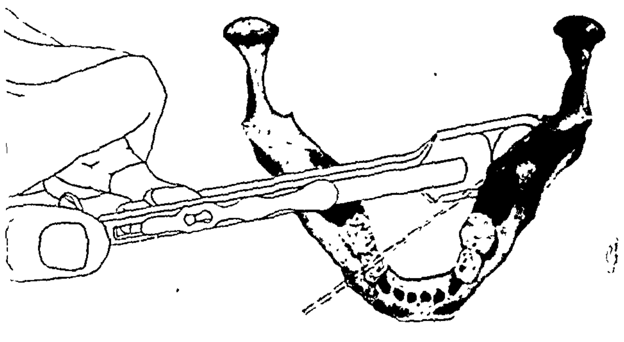

Fig. 5.—A young jaw showing guillotine in position. The dotted lines show the usual position of guillotine for mature jaws.

The blade must slide to and fro with the least possible friction. The aperture is elliptical, with its long axis transverse to that of the shaft. Its distal arc should be lined around with a soft metal into which the dull blade may be forced in the act of cutting through the tissues. The surgeon should have two guillotines, one with an aperture 2.5 cm. by 1.8 cm., the other 1.75 cm. by 1.5 cm. The two instruments should be alike in every measurement except the distal part of the shaft which bears the aperture; the two should be of the same great strength. If the shaft is not strong enough it will be bent slightly in the act of operating and then the blade will not slide with the ease that is required of this instrument. If the handle is not securely attached to the shaft it will be broken off during the operation.

---

[5] Bell, Benjamin: System of Surgery, 1783, iv, 144, Plate 52, Fig. 1. Quoted by Mackenzie.

ANATOMIC RELATIONS

In the following use of terms indicating direction I assume the body of the patient to be erect and facing the surgeon. I have already mentioned that one of the essential and distinctive features of this method is the utilization of the alveolar eminence of the mandible in manipulating the tonsil. I have also stated that this eminence is made by the internal ending of the alveolus, with the gum covering it.

It should be remembered that the tonsil lies posterior to and for the most part below the eminence, in childhood appearing much further back and much lower than in maturity. This arises from the fact that an uncut tooth is in the alveolus posterior to the one showing through the gum membrane, causing a greater elevation at this site and making it seem that the teeth are much further forward, and the tonsil lower. In cases of great enlargement of the tonsil more of it will lie even with or a part may possibly lie above the eminence. It will also extend forward, approaching the eminence from behind.

The surface of the jaw-bone posterior to and below the eminence slants downward, backward and outward at an angle that may vary considerably, but is approximately 45°—that is 45° downward and outward from the transverse, and at the same time 45° outward and backward from the anteroposterior axis. This slant arises in large part from the fact that the alveolar arch as it proceeds backward tilts more and more inward from the body of the jaw. Its posterior end faces inward as well as upward (Fig. 2, I *A*). Looking backward or downward it is seen that the ending of the alveolus lies completely internal to the line of the buccinator ridge were it prolonged as it descends on the coronoid process (Fig. 2, I *B*); and the impression thus given is that this line when carried downward represents the jaw proper and that the end of the alveolus lies internal to it. This is shown better on mature jaws. This slant is crossed by the mylohyoid line, which is well marked in maturity. On young jaws this surface is more nearly smooth, although that marking is always to be seen.

The angle of this slant is subject to considerable variation because the relation of the breadth of the alveolus to the height of the horizontal portion of the jaw (alveolus and body together) varies very much according to age. The breadth of the alveolus in the young is actually wider (3 mm. sometimes) than that of the adult. This is true for two reasons: (1) that in the young, these alveolar dimensions are made by the crown of the molar, whereas in maturity they are made by its neck: (2) that although the tooth may be through, the bone surrounding it has not yet been absorbed to the extent that it is in maturity. On the other hand the height of the horizontal portion in maturity is twice that of early life, for the reasons that the young jaw consists largely of alveolus, and that the body is added to it only by development with the years. For these reasons the angle of the slant in young jaws may rise to even more than 60° outward and backward from the anteroposterior axis (Fig. 5), and to even more than 60° downward and outward from the transverse; while in maturity these angles may be less than 45° in one or both directions. The alveolar eminence is therefore very much more prominent in the young, despite the fact that the inward tilting of the alveolus is greater in maturity than in early life. The edentulous jaw need scarce be considered in this connection, because the operation in question is rarely needed by the aged. Anatomically, however, it is usually marked by a very heavy mylohyoid line which, since the absorption of the alveolus, lies near the upper margin of the body which alone remains. There is usually a trace of the alveolar eminence still to be observed.

These differences may be accurately estimated in the living by introducing the index-finger into the patient's mouth, downward, outward and backward from the alveolar eminence pushing the soft tissues aside as far as may be necessary. It is distinctly advantageous to make this estimate just before operating in order that the direction of the guillotine may be varied to suit that individual's requirements. The buccinator ridge is frequently helpful in making this estimate.

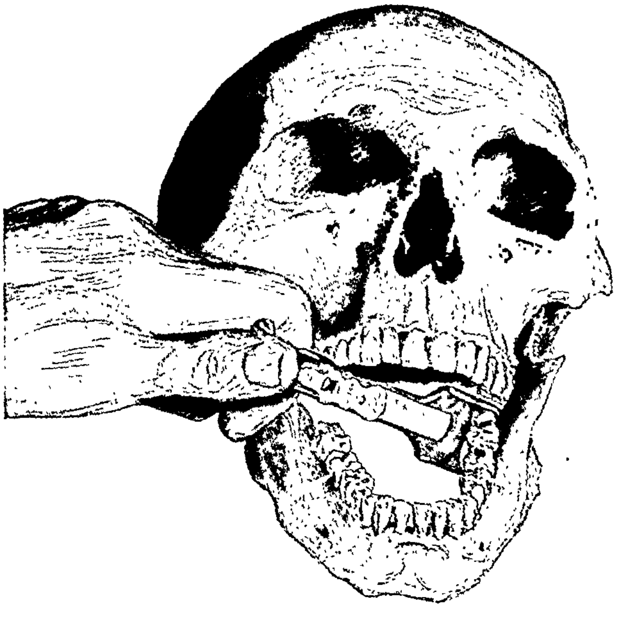

Fig. 6.—The guillotine in position, showing its general relationship to the bones.

THE OPERATION

In order to use the alveolar eminence of the mandible as a vantage-point from which to manipulate the tonsil—that is, to use this prominence to put or help to put the tonsil through the aperture of the guillotine—it is necessary to move it completely from its normal position which is posterior to and below the eminence (see above). It must be moved forward and upward. The elasticity of the soft parts of the throat readily allow the necessary movement. In this way the tonsil will be moved out of a hollow, soft, moving bed and be brought up on to a motionless, hard hump—a solid, fixed, somewhat hemispherical convexity.

Under these altered conditions it is not difficult to place the blade of the guillotine at its base. The eminence is then sometimes found to be all that is required to hold it for a perfect adjustment of the instrument, which is done by pressing it against the bone. The prominence of the eminence then stuffs the tonsil through the aperture. Often, however, in operating, especially with a large, flat (thin) imbedded tonsil, it is necessary to use the tip of the index-finger of the other hand to put the final bit through. If it be soft in addition to these qualities, the difficulty is increased to the fullest possibility. A firm tonsil is manipulated without difficulty, regardless of size or imbedding, provided it be not too thin (flat). Should it be soft, large, flat (thin) and imbedded, great care and some dexterity must be exercised in order to secure it entire.

Under these conditions the surgeon will find sometimes that he has removed only the central portion of the capsule with tonsil tissue surrounding it. A little more familiarity with the method and possibly a little greater dexterity in managing the instrument will usually permit him to secure it entire. (I can, however, picture to myself a tonsil that is so soft, thin and spread out that it could not be removed entire with one stroke, despite all the care and dexterity that might be exercised; but it must needs be rare.)

Under conditions presenting difficulties a perfectly satisfactory guillotine is indispensable. Precise knowledge of the topography and all the variations is necessary at all times.

THE OPERATIVE PROCEDURE

The use of this type of instrument, so far as I am able to learn, has always been by preference with the smooth (proximal) side of the blade applied to the tonsil. Mackenzie[1] made his modification with its detachable and reversible handle that this might be done more readily (see above). Its method of use was, that it was inserted into the mouth in an anteroposterior direction and the aperture put over that part of the tonsil which protruded beyond its surroundings into the cavity of the throat. The blade was then pushed across, cutting off that portion.

With my method one must approach the tonsil at an angle, approximately 45°, which requires the shaft of the instrument to cross the mouth entirely from the opposite side. This necessitates the distal side of the shaft being applied to the tonsil. It at the same time has the great advantage of leaving the lateral portion of field of operation wide open for view and the use of the fingers of the other hand. Having the blade ground far back widens it further. (The use of the proximal side will be found exceedingly awkward or even impossible as the surgeon's hands are interfered with and the lateral portion of the field of operation covered from view.)

It is a very great advantage to operate on the right tonsil by holding the guillotine in the right hand and on the left tonsil by holding it in the left hand. If the surgeon can use only one hand, the position of the patient should be recumbent. Assuming that he uses his right hand for both tonsils and stands on the patient's right: for the right one he faces the patient's head; but for the left one he must turn around so that he faces the patient's feet, and stand somewhat beyond (above) his head. (These relations might be sustained in the erect posture also.) The head should be held firmly by an assistant to prevent rotation, and the mouth kept fully open by a gag.

Regardless of what may be the position of the patient's head, the surgeon takes his bearings from the lower jaw. The guillotine, with the transverse axis of the aperture vertical, is introduced into the mouth at an angle of 45° outward and backward, passing back until the distal arc of the aperture is completely behind the tonsil. The direction of the shaft is then changed to point downward in order to get the ring of the aperture under the lowermost part of the tonsil. The instrument at this moment may sometimes to advantage be rotated slightly by turning the handle downward (toward the feet). This tends to enlarge the field of vision. It is then pressed outward until the distal arc of the aperture has been pressed against the ramus of the jaw, or, in case the patient is not anesthetized, against the firmly contracted internal pterygoid muscle which is inserted here. It is now brought slightly forward and upward, but held firmly against the bone and muscle, when it will be seen that the lower distal arc of the aperture has acted very much like a scoop, having secured the lower part of the tonsil and brought it forward and upward into the neighborhood of the alveolar eminence. In case the shaft has been rotated to secure its lower part, it is now put back into its original position by turning the handle upward. The upper portion of the tonsil is usually put into the grasp of the distal arc of the aperture by this rotation. If the tonsil is not too large and flat (thin) it is usually secured, both lower and upper portions, in the first setting of the guillotine and no rotation is needed. The distal arc of the aperture is now firmly held behind the posterior border of the tonsil and the instrument drawn forward and upward at an angle approximately 45°, which will be found to have pulled it upward and forward onto the eminence of the alveolus. The blade is now pushed down with the gentlest possible pressure until the surgeon sees that it is in contact with the tissues. It should not be pressed forcibly until the parts are engaged satisfactorily in the aperture. The blade, being in contact with the tissues, prevents the portion of tonsil which has gone through from slipping out again.

At this moment the surgeon may perceive that although the distal arc of the aperture is entirely behind and external to the tonsil, a part of its anterior portion has still not gone through. This is usually readily seen, but may be more definitely determined by feeling with the tip of the index-finger of the other hand; and at the same time it may be pushed through. This is done by the gentlest massage—simply stroking it in the direction of the aperture with the ball of the index-finger and, at the same time, pushing the blade very gently across the remaining portion of the aperture. When the last of the anterior portion has gone through it may be readily seen as a rule; but may be determined with great accuracy by feeling with the ball of the index-finger—passing it up and down over the end of the blade as it closes the aperture. If all of the tonsil has gone through, the distal arc will be felt smooth and firm and to be covered by what seems to be a thick mucous membrane. (It is of course two layers of membrane.) If a part of the tonsil has not gone through, it can easily be felt and recognized as a mass of tissue harder than membrane and usually irregular.

All of the tonsil having gone through, the blade is now pushed across with all the power of the surgeon's hands. Great pressure is usually required because the blade has been made dull. If it be too dull or if it does not fit perfectly into the soft metal lining of the distal arc of the aperture, it will not cut altogether through. The instrument must then be pulled forward a little and its end be stripped off with the finger of the other hand. This does not delay the operation. It may possibly make a little more subsequent pain; but I am by no means sure that it does.

On examination of the extirpated tonsil while it is still held in the grasp of the instrument—that is, just as it comes from the patient's mouth—it will be seen that its surface which was exposed in the throat has the appearance of having been turned inside out (Fig. 4,I). On loosening it from the instrument it is seen that its capsule side—its lateral surface—bears further proof of this fact. The capsule appears completely invaginated (Fig. 4, II); but it can be readily replaced—that is, turned over into its original relations, thereby restoring the tonsil to its customary appearance, as it is in the throat (Fig. 4, III), covered on its lateral, convex aspect by the capsule (Fig. 4, IV). This phenomenon is readily explicable when one remembers that it was brought up on to the eminence to have the ring of the guillotine, as it were, stuffed down over it, converting its convex bed into a concave one at the time of cutting. Further examination of the specimen reveals that a little of the free edge of the anterior pillar, including a few fibers of the palatoglossus muscle, is attached to it. I always remove this bit of the anterior pillar with the tonsil because it leaves a more open wound and a more open fossa when healed. There seems to be no surgical reason against it; on the contrary, it makes the tension of the scar begin at a point anterior to and below what would otherwise be the case, which tends to draw the palate forward and downward. In cases in which the tonsil is to be removed because of Eustachian tube irritation this seems to me to be advantageous. In operating under general anesthesia I prefer to have the pharyngeal reflex present. I much prefer to have the aperture fit rather snugly over the tonsil.

This method will be found to be satisfactory under all usual conditions, provided the variations in the jaws of different ages are borne in mind. For the young jaw the angle of the instrument must sometimes be increased to even more than 60° outward and backward and to even more than 60° downward and outward. It does not require grasping the tonsil in a vulsellum and pulling it out. The imbedded tonsil is usually removed as easily and as quickly as the protruding one (see above). No loosening of the pillars is required, because I prefer to take a little of the anterior one. Familiarity with the method will enable the surgeon to remove a tonsil in its capsule complete in from five to eight seconds. I think that the shock from this method is less than from the longer operations.

Stumps of tonsils left from previous operations are usually as easily removed as the original tonsils.

3542 Washington Avenue.

Intestinal Sutures.—The evolution of the intestinal suture has brought us to the point where we are certain of good results when the sutures are properly applied and are of the right material. Non-absorbable suture material should be cast off into the lumen of the intestine after serving its period of usefulness. This is best accomplished when used for the inner layer. There is also less destruction of tissue. When placed externally it promotes unnecessary adhesions, plastic exudate and fibrous bands, and may interfere with the proper bowel function because of its prolonged irritation. Absorbable suture material used for the outer layer is soon taken care of, and does not cripple the action of the intestine. The suture in intestinal work must control hemorrhage, secure proper coaptation of the tissues, prevent leakage, avoid pursing, be quickly introduced and must not strangulate the tissue. The back lockstitch of Pagenstecher's thread serves all these purposes. Experimental work has demonstrated that chromic catgut when employed as the outer suture lasts sufficiently long for positive and firm union to occur.—A. E. Benjamin, in the *Lancet-Clinic*

LIPOMATOSIS OF THE LOWER EXTREMITIES WITH REPORT OF A CASE

W. R. MacAUSLAND, M.D.
Orthopedic Surgeon, Carney Hospital
AND
B. E. WOOD, M.D.
Assistant Orthopedic Surgeon, Carney Hospital
BOSTON

This case of lipomatosis of the lower extremities is reported on account of its rarity. Its steady progression suggested a malignant process. No literature is found bearing on this subject.

Patient.—R. R., a girl aged 10, was seen in consultation with Dr. B. L. Dwinell of Taunton, Mass., Dec. 8, 1907. She had suffered since birth with slowly progressing deformity of feet. The family history was negative. "Both feet at birth were shaped like animals' feet, and much larger than normal in proportion to the body; weight at birth, 4½ pounds. Patient had on left side a peculiar mark which looked like an old burn: otherwise had been normal and healthy. The patient's mother was not as well as usual when carrying the child, and had a great deal of pain at night. At the age of 6 months, the child's toes were amputated. At this age the feet were noted to be growing faster than the rest of the body. At the age of 10, patient weighed 70 pounds. From this time on the left leg, especially, grew very fast. The mental development of the child had been excellent. She walked and ran like the other children, but tired very easily. Feet sounded not unlike elephant's feet when walking." Double amputation had been advised.

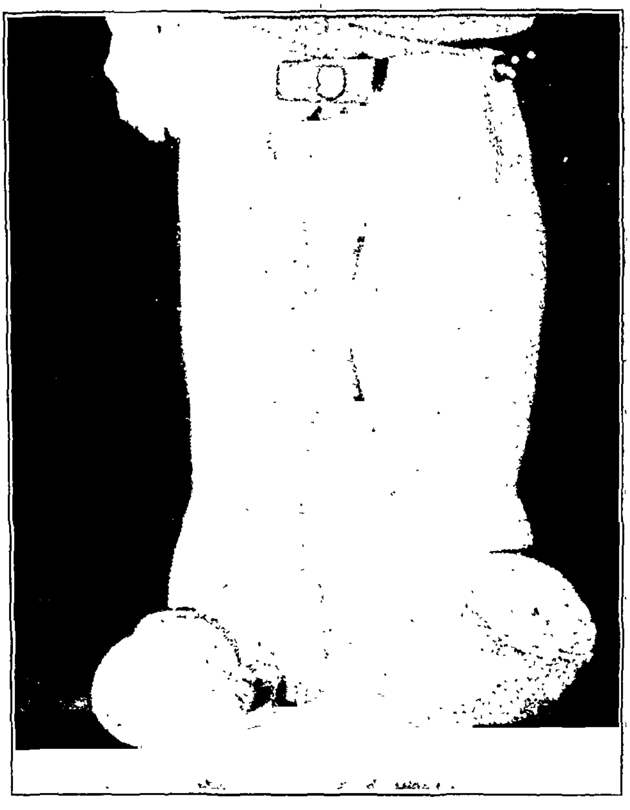

Fig. 1.—Lipomatosis of feet and legs; front view.

Examination.—General condition fair. Patient was thin and had a peaked expression; seemed active and well; pulse slightly rapid at the time of examination. Running down the left arm and leg was a crusty, eczematous lesion, not progressive. The left foot was larger than the right, but both feet were markedly enlarged and lobular in character, the swelling involving the whole of both feet. The same lobulation extended up to the knee, but was there less marked than in the feet. Masses the size of two fists stood out on the left calf. These were not adherent, and could be easily picked up. There was a pad of fat about 4 inches thick on the left foot. The dorsum of the foot was probably five or six times the normal in circumference. Examination of heart, lungs, and abdomen were negative. Urinalysis was negative.

The patient had not been seen for about two months prior to this date, Feb. 16, 1908, during which time the legs rapidly increased in size. A consultation was held with Dr. E. G. Brackett, and we advised conservative operative treatment before amputation was done.

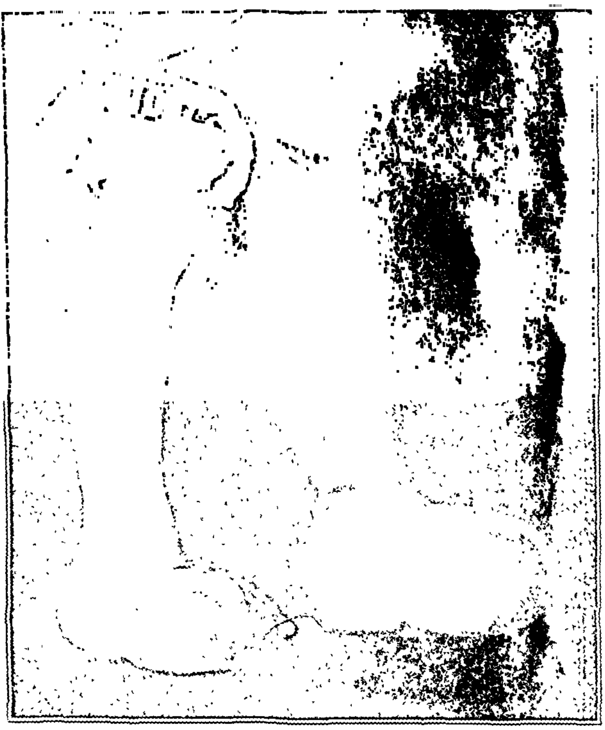

Fig. 2.—Lipomatosis of feet and legs; lateral view.

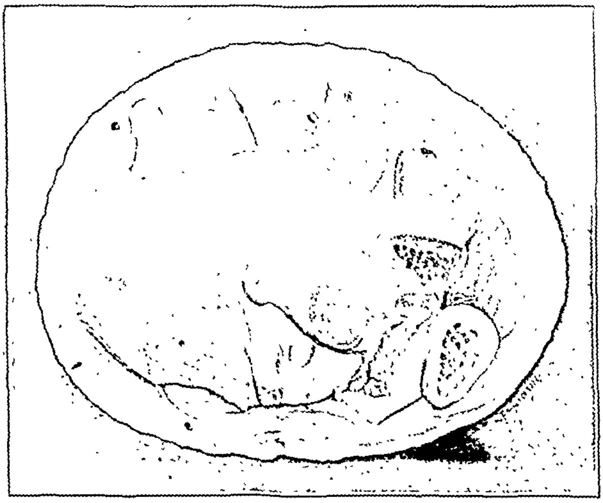

Fig. 3.—Cross-section of amputated left foot.

Feb. 29, 1908: Radiograph of left foot, and also photographs were taken (Figs. 1 and 2).

Operations.—March 30, 1908, ether was given and operation performed. An incision running from the tibial tubercle on the outer side of the left leg was made down to the ankle-joint. Masses of fat, encapsulated and running between and into the muscles, were dissected out. Some were easily taken out by blunt dissection, while others seemed a part of the muscle substance. The muscle was pale and there was considerable fatty tissue between the fibers. The operation lasted three hours. The wound was closed with silkworm gut and a slight drain left. Recovery from the ether was poor. Patient had an elevation of temperature for three days, and then became normal. There was considerable shock. The convalescence was otherwise uneventful.

April 20, 1908: Under ether a similar operation was done on the right leg. As much of the fatty tissue as possible was dissected out. The wound was drained. There was some sloughing of the skin flaps. Convalescence was otherwise uneventful.

May 17, 1908: Results from previous operations were good; still there was a large amount of fat on the feet; patient was gaining in weight.

Oct. 11, 1908: A second operation was done on the right foot. A large amount of fat was dissected from plantar surface of the foot. Patient made a very poor recovery from the ether. On the second day she had a pulse of 160 and temperature of 103 F., but under treatment recovered.

The skin flaps in these operations even under hot towels grew cold. Sloughing of the flaps occurred after each operation. Following each of these three operations the patient suffered shock, although the last operation lasted only about one and one-fourth hours. The patient's general condition seemed poorer each time, and there was a very marked increase in weight throughout the whole body, but especially in the abdomen.

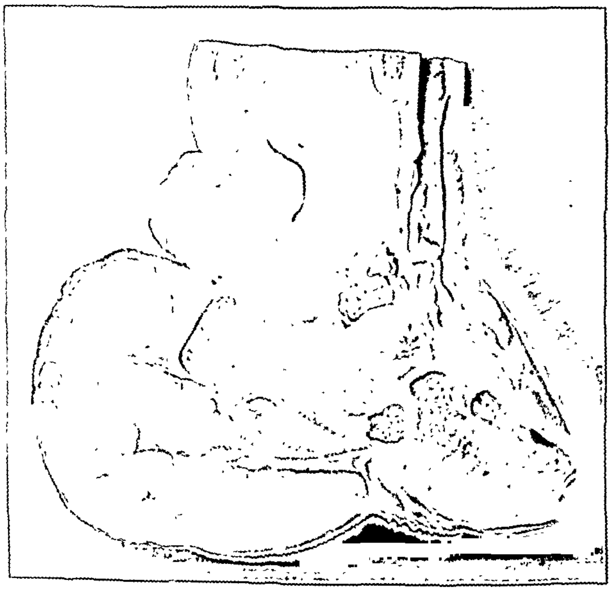

Fig. 4.—Longitudinal section of amputated left foot and leg. Note the lobular fatty deposits and fatty infiltration and degeneration of muscular tissue.

The patient now weighed 137 pounds at the age of 12. It seemed as though she would not be able to withstand more operations. The confinement to the house told on her general condition. The right leg, while not normal, was about one-half the size that it was previous to the operations. The left leg, not having been controlled by operation, had continued to grow. Amputation of the left leg was therefore advised. Dr Dwinell of Taunton was seen in consultation.

March, 1910, under ether, a regular amputation of the left leg was done at the point of election; silkworm gut sutures were used. There was a good recovery from the ether.

The general condition of patient has been materially better since this operation. She now walks about well with crutches, while awaiting an artificial limb. The right foot has ceased to grow.

Vertical and cross sections of the amputated foot, natural size, are shown in Figures 3 and 4.

411 Marlborough Street.

ANGIOSARCOMA OF THE LIVER IN AN INFANT

JULIUS BONDY, M.D.
NEW YORK

Case.—Baby N., born April 10, 1910; male, second child.

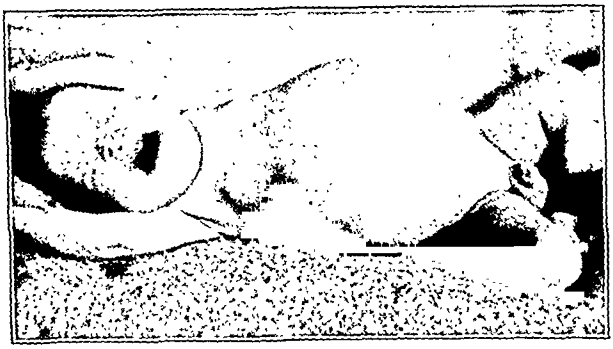
Family History.—The history of the father and mother, as well as that of the grandparents on either side, showed absolutely no record of malignant growths. The mother's age was 28; that of the father 32.

Past History.—The child was delivered instrumentally, due to *inertia uteri.* It had no deformities and seemed to grow normally until the third week.

Present History.—Three weeks after the birth of the child, while the mother was bathing it, she noticed that the child's abdomen was somewhat protuberant. One week later the child was brought to me for this reason alone. No other symptoms of disease had been noticed; the local condition was evidently as yet causing the child no inconvenience. The stools were normal and digestion good. The child was breast-fed.

Examination.—The child was somewhat pale and languid. The head and neck were normal; there was no glandular enlargement. The apex of the heart was in the fourth intercostal space, in the nipple line; no murmurs were heard. Lungs were normal. No deformities of either extremities.

The abdomen was markedly protuberant, especially in the upper right hand quadrant, and dilated veins were perceptible over the liver region. The circumference of the abdomen was eighteen inches at a point one and a half inches below the costal border. Percussion gave a flat sound over the upper three-quarters of the abdomen. On palpation, an indistinct mass was felt filling both sides of the upper abdomen. The surface of the mass was smooth and the edge was distinctly palpable below the umbilicus. This mass could not be definitely connected with any organ.



Enlargement of abdomen from angio-sarcoma of liver in an infant aged 3½ months.

Exploratory Operation and Findings.—The case was referred to Dr. Henry Roth, attending surgeon to Lebanon Hospital, and he performed an exploratory laparotomy over the mass in the median line, which showed the tumor to be an enormously enlarged liver, filling three-quarters of the abdominal cavity. The liver was dark brown in color and mottled with small blue areas averaging one centimeter in diameter. Its surface was smooth. The spleen and kidneys were not enlarged, nor was there any apparent invasion of any other abdominal organ.

A small section of the liver was removed from the upper surface for microscopical examination and the abdomen closed. The child made an uneventful recovery from the operation. Following the operation, the child's girth progressively increased, until, just before its death, at the age of 3½ months, it measured twenty-nine inches at the umbilicus.

The extremities became edematous, but at no time was there ascites or jaundice. Diarrhea finally set in and the child died of exhaustion. No autopsy was permitted, although strenuous efforts were made to obtain it.

The section of liver removed at the time of operation was sent to Dr. Eugene P. Bernstein, pathologist to Lebanon Hospital, who reported it to be angiosarcoma.

This case is reported because of its extreme rarity and the difficulty of making an accurate diagnosis. On reviewing the literature, I find that Arnold[1] reports two cases. The first of these was in a boy of 15 years, and the second in a man of 53 years. Both died in a short space of time, and the diagnosis was apparently made at autopsy. Arnold, after reviewing several cases of malignant disease of the liver, comes to the conclusion that several of these cases strongly resemble angiosarcoma of the liver. Dervaux[2] reports a case of angiosarcoma of the liver, secondary to sarcoma of the testis.

The chief features in my case are, first, the early period of life at which the tumor started (possibly during gestation); second, the rapid increase in abdominal girth; third, the early death of the infant; and last, the paucity of symptoms noticeable until just before death.

1266 Boston Road.

A SIMPLE APPARATUS FOR PROCTOCLYSIS

PERCIVAL NICHOLSON, M.D.
ARDMORE, PA.

Not knowing whether any one has been using a similar apparatus, but not having seen anything like it mentioned in the medical journals, I wish to describe a simple apparatus which I put into use in the Presbyterian Hospital in Philadelphia in 1910, which fulfils all the requirements for carrying out the drop method of proctocylsis.[3]

It is simplicity itself, the requisites being a glass cylinder of 4 oz. capacity, drawn out at the end to carry rubber tubing; a No. 7 rubber stopper with a hole in the middle to carry a pipette, and another hole in the side for an air vent; a Moore pinch-cock, and a proctoclysis nozzle.

To apply the apparatus simply take an ordinary fountain syringe, found in any household, cut the tubing about three inches below the bag, put the pinch-cock on the short tube thus formed and shut it off tight about 1½ inches from the bag. Now run the short end of the tube over the pipette, securing it with a ligature. To the lower end of the glass cylinder attach the remaining rubber tubing, and in place of the ordinary irrigation nozzle apply a hard rubber proctoclysis nozzle. Then fill the bag with normal salt solution and run the lower end of the tubing between two hot water bags. The illustration shows the entire apparatus assembled and the bag filled with salt solution (which is well to have warm, though that is not of great importance). A short distance from the nozzle the rubber tubing is carried between two hot water bags partially filled with water at about 150 to 175 F. Clinically it has been found that the salt solution, passing, as it does, a drop at a time between the two hot water bags, is thus heated to the proper temperature before entering the rectum. The temperature of the solution in the douche bag is not of much importance, as it will be cooled in dropping into the cylinder. Both hot water bags are surrounded by a blanket which acts both in retaining the heat and in protecting the patient's skin from burning.

---

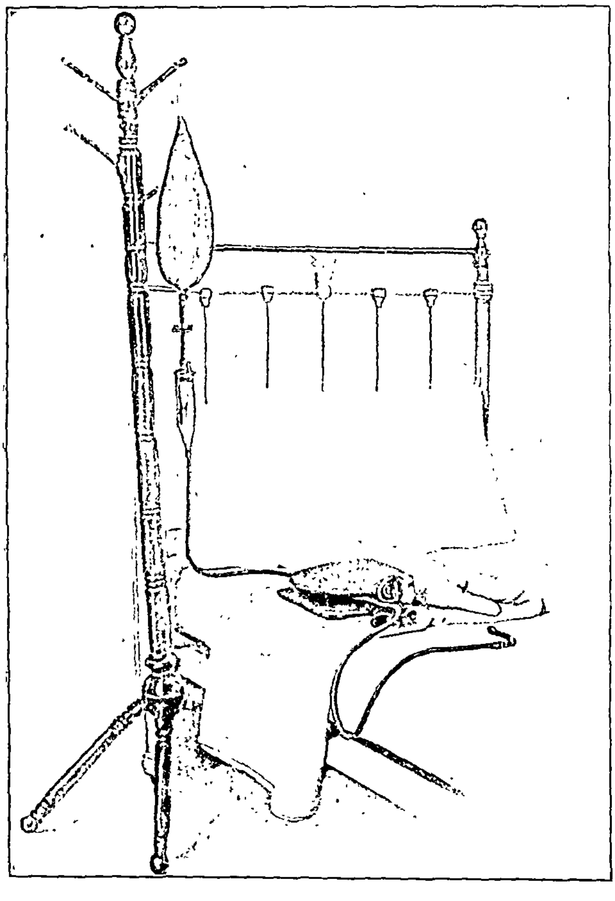
[1] Beitr. z. path. anat., 1890, viii, 123.

[2] Journal de sc. méd. de Lille, 1902, xxv, 131.

[3] Since the above was written there has appeared in Surgery, Gynecology and Obstetrics an article by Dr. W. A. Dewitt of Philadelphia describing the same apparatus, with a slight modification, leaving it to be inferred that it was original with him. Dr. W. A. Dewitt was a resident in the Presbyterian Hospital in Philadelphia at the time I introduced and first put in operation the apparatus described above, with the origination of which he had nothing whatever to do.

Having set up the apparatus, loosen the pinch-cock until the solution drops from the pipette at the rate desired; then introduce the nozzle just within the sphincter. It will be noticed that an important feature of this apparatus is that its operation is always capable of inspection.

Should the nozzle become blocked, a rise of fluid in the cylinder will be noticed, and by shutting the pinch-cock and removing the rubber tube from the lower end of the glass cylinder a small quantity of salt solution can be forced by means of any syringe through the lower tube and thus clear the opening in the nozzle without removing it from the rectum; then by reattaching the tube to the glass cylinder and opening pinch-cock the flow is reestablished.



Illustrating parts of proctoclysis apparatus assembled ready for use.

As only the contents of the small glass cylinder and the small column of water in the tube press on the bowel, the bag can be raised to almost any height desired without causing expulsion of fluid alongside the nozzle; but the best results are attained when a moderate elevation of from two to three feet is maintained.

This apparatus has been in use for over one year with marked success, and its simplicity admits of its use in general practice as well as in hospitals, as it is inexpensive, efficient and cleanly, all parts being capable of sterilization.

Attractive Diet in Neurasthenia.—In order that a diet may be available, it must be palatable, and especially is this the case in dealing with neurasthenics.—D. N. Paton in the *Practitioner.*

A NEW METHOD FOR APPLYING PLASTE JACKETS IN HYPEREXTENSION *

PERCY WILLARD ROBERTS, M.D.
Assistant Orthopedic Surgeon, City Children's Hospital; Clinica Assistant, Hospital for Ruptured and Crippled; Instructor in Orthopedic Surgery, Post-Graduate Hospital; Instructor in Orthopedic Surgery, Cornell University Medical College
NEW YORK

There seems to be little diversity of opinion as to th theoretically simple mechanical problem involved i treatment of Pott's disease. The object is to support a upright column which has become weakened at one poin and either bends or threatens to bend, and at the sam time to abolish or minimize friction on the articula surfaces of the diseased vertebral body, thereby lessenin the likelihood of deformity and giving Nature opportunity to limit the lesion and to effect a cure. In dealin with the flexible spine there is but one way to accomplis this, and that is by throwing the burden of weight-bearing on the articular processes—in other words, t put the spine in a position of hyperextension. Thi would seem simple enough, and yet the study of a larg number of hospital cases forces the conviction that it i seldom achieved by present methods. There are variou roads to the end sought. One may choose the spina brace, the gas-pipe frame or the plaster jacket, but it i the last of the three that will here be considered, fo the jacket has many advantages in hospital and dispensary practice.

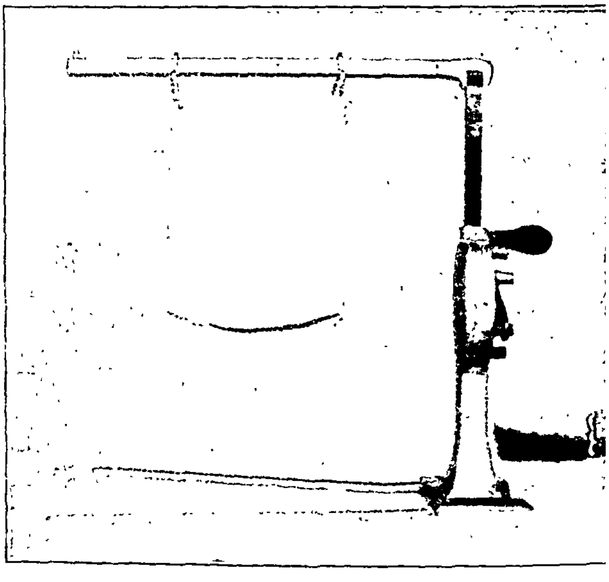


Fig. 1.—Roberts' jacket and sling.

Except in certain localities, notably Boston and Baltimore, it is the custom to apply plaster by the Sayr suspension apparatus or some modification of it, an this of itself is eloquent testimony of the value of a method which has undergone so little change in nearl forty years. But no one ever asserted that the Sayr method produced hyperextension. It does not. It is nevertheless, a simple and effective way of securin immobilization, and the results obtained by it hav warranted its continued use over a long period of time. Realizing its one shortcoming, a number of men have produced devices for applying plaster-of-Paris jacket in hyperextension. These have been effective, but fail either in the element of simplicity or in accuracy, or both, and consequently have not been widely accepted in routine work. To overcome such objections I have evolved an apparatus which utilizes the bandage sling in combination with an ordinary jack, the simplicity and efficiency of which are shown in the illustrations.

---

* Read before the Orthopedic Section of the New York Academy of Medicine, Nov. 18, 1910.

To determine just what is accomplished in the way of position by the use of the familiar head-sling, tracings have been made in about fifty cases with the patients prone on a hard table and strung up ready for a jacket. Most of these showed some correction of deformity, but only a little, as will be observed on referring to lines 1 and 2 (Fig. 2) of the tracings presented herewith, which are typical of the entire number. In contrast with line 2, traced by a lead tape with the patient in upright suspension, is the third of each set, which gives the contour of the same spine suspended by the jack and sling.

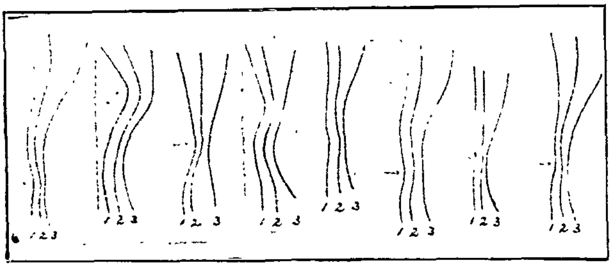

Fig. 2.—Tracings showing correction of deformity obtained by "jack and sling." 1, contour of spine with patient prone on a hard table; 2, contour of spine with patient in upright suspension; 3, contour of spine with patient suspended by "jack and sling."

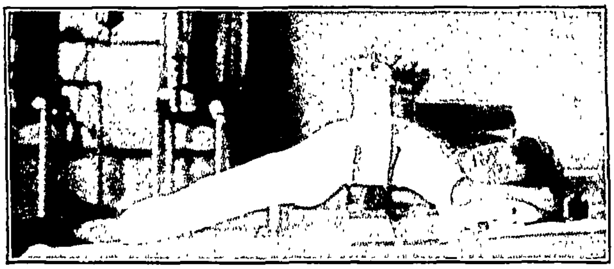

Fig. 3.—Patient suspended by "jack and sling" ready for jacket. Note extent and thickness of padding.

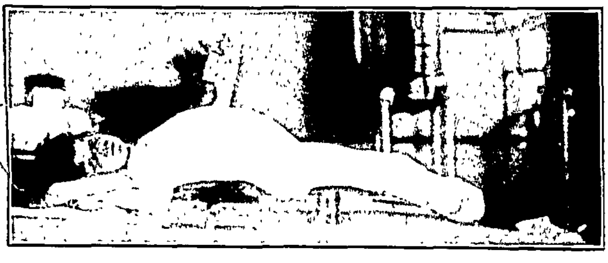

Fig. 4.—Jacket finished but not trimmed.

The apparatus illustrated in Figure 1 consists of an automobile jack, to the movable upright of which is attached a horizontal bar, and to the base two foot-pieces to insure lateral stability. On the bar are two shaped wire loops, over which are pinned the ends of a muslin bandage. Its simplicity is evident.

It is used as follows: The patient lies on the back and a two-inch muslin bandage is passed under the body, bearing exactly on the kyphos; the bandage is padded generously the whole breadth of the body. This form of padding, which is a departure from ordinary practice, is absolutely essential to avoid excoriations. Felting at least one-quarter of an inch in thickness is the best material for the purpose. The ends of the bandage are pinned over loops on the horizontal bar and the jack is set in motion, a hip-rest and shoulder-rest being placed in position as the patient rises. The desired degree of hyperextension having been obtained, the usual pads to protect the spinous processes and iliac prominences are placed in position. The plaster bandage is started at the pelvis. When the suspending sling is reached, the bandage is crossed over the body from the lower border of one upright to the upper border of the other. To give strength to the front of the jacket several folds of plaster bandage are passed longitudinally between the muslin supports, being carried down on either side of the sling as it leaves the body. When the cast has hardened the sling is cut away close to the jacket. It is unnecessary to close the remaining slits except for appearance, as they in no way interfere with the strength of the jacket.

In simplicity, the jack and sling compares favorably with the usual method of upright suspension. By allowing the terminal parts of the spine to fall automatically and abruptly away from a narrow point of support it secures the greatest degree of hyperextension obtainable in any given case within the limits of safety. Further advantages over the upright method are greater steadiness of the patient, greater comfort of the patient, an easier attitude for the operator, less splashing of plaster, greater convenience in the application of jackets away from the plaster room—that is, in the home or hospital wards—the requirement of fewer assistants, and, of greater import than all the rest, the natural assumption of a better mechanical position for the diseased spine.

With this apparatus, I have applied jackets on patients ranging in age from 3 to 40 years, and in weight from 30 to 140 pounds, and all have been apparently comfortable. By the use of two slings, Calot jackets and jackets with jury-masts may be applied. While it is too early to report a convincing series of cases, there is reason to believe that persistent use of the jack and sling method, with frequent changing of jackets, will show a real correction of deformity in a large percentage of long-standing cases.

PRIMARY SUTURE OF SUBPARIETAL RUPTURE OF KIDNEY

WITH REPORT OF CASE *

F. GREGORY CONNELL, M.D.
OSHKOSH, WIS.

CASE OF SIMPLE SUBPARIETAL RUPTURE OF LEFT KIDNEY, LUMBAR INCISION AND SUTURE OF KIDNEY FORTY-TWO HOURS AFTER ACCIDENT, RECOVERY

History.—M. M., a schoolboy, aged 11, about 8:30 a. m., Oct. 26, 1910, in attempting to alight from a moving bicycle, slipped and fell, striking his right lumbar region against the edge of the street curbing. There was very severe pain in the right loin, but no collapse, shock, or vomiting; but for a period of about five minutes he was unable to walk because of general weakness, with dizziness and nausea. After a short rest, in a sitting, doubled-over posture, he was able to walk a distance of about half a mile to his home, and as he still complained of very severe pain he was put to bed.

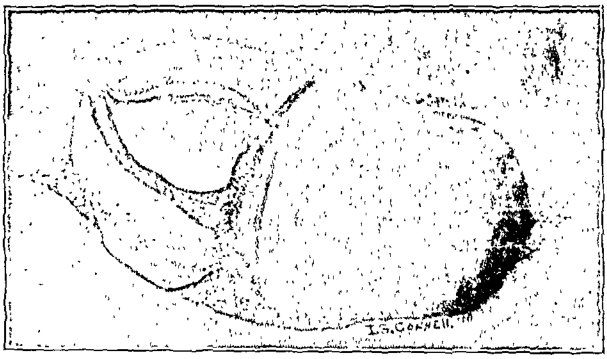
---

* Read at the meeting of the Western Surgical Association, December, 1910.

Dr. F. W. A. Brown was called and examined the boy very carefully. There was no fractured rib or evidence of serious injury, the tenderness and rigidity in the lumbar region being the only apparent result of the tumble the boy had taken. The severe pain persisted until about 1:30 p. m., when about 8 ounces of bloody urine were passed, after which the pain was markedly lessened; half an hour later vomiting occurred, after which there was a still greater sense of relief.

Examination.—About 2:30 p. m. I saw the patient in consultation with Dr. Brown, at which time the boy did not complain of much pain, other than a severe and constant ache in the left lumbar region. One was impressed at once, by the "bad appearance" of the patient. The skin was sallow or yellowish and the face had a drawn, anxious expression, despite the fact that the boy was making light of his injury and was asking for some chewing-gum. Pulse, temperature and respirations were normal; there was no dyspnea but deep inspiration caused pain under the left lower ribs. Abdominal palpation revealed marked rigidity and tenderness in the region of the kidney, more marked posteriorly. Deep palpation was impossible, and a tumor mass could not be made out, either by palpation or percussion. There was no free fluid demonstrable in the peritoneal cavity, nor was there any external evidence of the injury.

Diagnosis.—Because of the nature of the trauma, hematuria and rigidity of muscles in the region of the kidney, rupture of that organ was diagnosed, and exploratory incision advised. This advice was refused.



Illustrating the author's case of a stellate, traumatic rupture of the kidney, extending into the pelvis, in a boy aged 11.

Course of Injury.—During the following afternoon and evening the boy was better, in that the pain was not so severe, but he was unable to rest because of the constant dull ache at the site of the injury, and the passage of bloody urine about every hour. The act of micturition was without pain or tenesmus. The next morning there was an attack of vomiting, the bloody urination continued, and the patient became drowsy and weaker. The parents then became alarmed, realized the seriousness of the boy's condition, and sent him to the hospital for operation. On admission the patient was very weak, unable to sit up, the face was drawn and pinched, and there was a distinct yellowish tinge to the skin. His only complaint was a dull ache in the lumbar region, with a more severe pain on moving. Examination revealed a distinct fulness in the left iliocostal space, with marked tenderness on pressure; there was rigidity of the lumbar and abdominal muscles, and on bimanual palpation a mass could be detected, which was dull on percussion, but there was no free fluid in the peritoneal cavity. The temperature was subnormal, pulse 130, small and collapsible, and the respirations 24 and superficial.

Operation.—This was performed at St. Mary's Hospital, Oct. 27, 1910, at 2 p. m. Ether anesthesia administered by Dr. W. P. Wheeler, and Dr. F. W. A. Brown assisting, the kidney was approached through the usual lumbar incision. Division of the transversalis fascia revealed the fatty capsule of the kidney, through which blood was apparent, similar to the appearance of the peritoneum in cases of intra-abdominal hemorrhage. Division of this capsule was followed by the escape of considerable blood and many clots. The kidney was promptly delivered through the wound, and examination revealed a stellate tear extending into the pelvis of the organ in the upper pole of the kidney as shown in the illustration. A transverse tear was situated at about the junction of the upper and middle thirds, extending from side to side, practically separating the upper pole from the remainder of the organ. This upper fragment was divided into two unequal parts by a longitudinal tear extending from the transverse rupture to the upper extremity of the organ. This longitudinal tear was not located in the mid-line of the convex surface, but was situated about a quarter of an inch behind the mid-line at its lower part, and about half an inch behind, at its upper extremity, on a line probably analogous to the avascular line of Broedel. After cleansing the wound margins of blood-clot by salt sponges that passed into the pelvis, the wounds of the kidney were sutured with chromic catgut mattress stitches, which were inserted deeply into the parenchyma of the organ. Ordinary round curved needles were employed, and there was no tearing out of the stitches. After these deep mattress stitches were inserted and tied loosely, there was absolute control of the bleeding, and a layer of superficial circular or over-and-over stitches were inserted to effect accurate coaptation of the wound edges. An effort was made to close the fibrous capsule but this was found to be impossible. A cigarette drain was inserted to the lower pole of the kidney and the lumbar wound closed except at the passage of the drain.

Outcome.—Recovery was uneventful; there was very little discharge from the wound, no urine; and the drain was removed October 30. The patient was discharged with the wound healed, a perfect recovery, November 13.

REVIEW OF SUBJECT

That subparietal rupture of the kidney is not common is shown by the fact that in 1903 Watson[1] was able to collect reports of only 660 cases from the literature. Neilson[2] in 1908 added reports of thirty-four cases in which operation had been done, making a total of 694. In the same year Lardennais[3] collected reports of 771 cases (this, an inaugural thesis, has not been available in the original).

Since Neilson's report in 1908, I have been able to find either mere mention, or a more or less complete report, of 147 additional cases, in seventy-nine of which operation was not done and in sixty-eight operation was done. This rapid recent increase in the number of reported cases would tend to show that the above figures fall far short of the actual number of cases.[4]

Fredet (1 case): Rev. de gynéc. et de chir. abd., 1909, No. 2, Surg., Gynec. and Obst., 1909, ix, 696.
Bugbee (1 case): Med. Rec., Nov. 5, 1910.
Connell (1 case): Report herewith.
Griffith (2 cases): Brit. Med. Jour., April 25, 1908, p. 979.
Kaarsberger, H. (2 cases): Ugesk. f. Laeger, 1909, lxxi, 557. Abstracted in The Journal A. M. A., Aug. 21, 1909, p. ~~563~~.
Fischer (2 cases): Zentralbl. f. Chir., 1909, No. 33, p. 1156.
Martin (2 *cases*): *Old Dom. Jour. Med. and Chir.*, 1910, x.
Rossi (3 cases): Zentralbl. f. Chir., 1908, No. 16, p. 510.
Ponomarew (3 cases): Zentralbl. f. Chir., 1909, No. 13, p. 477.
Gibson: In a personal communication reports four cases.
Yoshikawa (5 cases): *Zentralbl. f. Chir.*, 1909, No. 18, *p. 655*.
Frank (5 cases): Arch. f. klin. Chir., 1907, No. 2; Year Book of Surg. (Murphy), 1908, p. 535.
Brewer (6 cases): Am. Jour. Med. Sc., May, 1908, cxxxv, 635.
Johnson (7 cases): Ann. Surg., 1909, l, 715.
Tromifow (20 cases from the Russian literature): Zentralbl. *f. Chir., 1908, No. 10, p. 312.*

The non-operative cases were reported by Frank, 34; Ponomarew, 29; Trofimow, 13; and Rossi, 3.

The kidney seems to be as well protected from injury as other of the abdominal viscera, if not better, yet the kidneys are the most frequently injured in case of abdominal contusion. The fact that there are two kidneys, one on each side, of course, accounts in a large measure for this frequency.

ETIOLOGY

The theory as to the cause that may explain a majority of the cases is that of Küster, in which the rupture is supposed to be due to hydraulic pressure acting through the full vessels and the pelvis and causing the organ to burst along lines radiating from the hilum toward the point of maximum impact against the lower ribs, the opposing resistance being supplied by the vertebral column.

Abdominal contusion most liable to cause damage to viscera, is that in which there is a sudden, strong impact against the anterior or lateral abdominal wall, often when the patient is taken unawares, and the abdominal muscles do not have time to contract in self-defense; such contusions are inflicted by a fall against a sharp object or blows from a hoof, a fist, a thrown ball, a carriage-pole, or a piece of wood from a circular saw. A simple fall on the feet, or muscular action alone, may produce rupture of the kidney; a dozen of the latter variety of cases are on record.

Another type of injury, such as being run over by a wheel, or crushed between car-bumpers, more often results in a complicated rupture. There is usually very little or no external evidence of injury in the former class of cases.

CLASSIFICATION

Ruptures of the kidney must be divided into complicated and simple. In the former there are additional injuries to other organs or structure; in the latter the kidney is the only organ damaged. A classification has been based on the extent of the damage to the kidney, but this is of very little clinical or practical value.

Simple rupture of the kidney is much more common than are the complicated injuries. In Watson's and Neilson's cases 512 were simple, and 125 complicated. This approximate proportion is maintained in the report of Frank, in which there were thirty simple and nine complicated.

SYMPTOMATOLOGY

A most important element in the recognition of these cases is attention to the history of the accident and the nature of the traumatism.

Shock and collapse are often absent or but transitory, and the lack of recognition of this fact has been the cause of mistaken diagnoses and delay in proper treatment in a great many cases.

Pain is usually very severe at the time of the injury. It may be diffused or localized in the kidney region. Its duration varies greatly, but it is usually present and is followed by tenderness and a dull ache in the region of the ruptured organ.

Rigidity of the muscles over the kidney, with tenderness on palpation, is practically constant, and is of great importance.

Hematuria is generally present; it may be delayed in onset, or may occur with the first urination. In cases in which the ureter is blocked with a blood-clot, with a transverse tear of the pelvis or ureter, or with complete pulpification of the organ, hematuria may be absent. It must be remembered that hematuria following trauma in the region of the kidney is not pathognomonic of injury to that organ, as the bleeding may originate in the bladder or urethra, or there may be a hemorrhagic nephritis, or idiopathic or other types of bleeding from the kidney.

Tumor in the kidney region, may be absent, may develop within a short time, when it is usually due to a perirenal hematoma, or it may be of late development. In such cases it is probably caused by infection, or more rarely, secondary hemorrhage.

DIAGNOSIS

The diagnosis of kidney lesion demanding an exploratory incision, may generally be based on a history of a particular abdominal contusion, with rigidity, tenderness or tumor and hematuria.

TREATMENT

Treatment may be expectant or operative. A most important feature of the treatment, and of great influence on the result, is a recognition of the indications for treatment, and the selection of the proper line of treatment for the individual case. The results are important from this point of view, and Watson's series shows, that with expectant treatment 27 per cent. of the simple ruptures resulted fatally; and in the complicated injuries that the death-rate was 91 per cent. Radical operative treatment, i. e., nephrectomy, resulted as follows in Watson's and Neilson's series:

Complicated, 51 with 21 deaths (41 per cent.).
Simple, 132 with 30 deaths (22.5 per cent.).

Conservative operative treatment, *i. e.*, gauze packing, drainage or suture, had the following results:

Complicated, 18 with 7 deaths (38 per cent.).
Simple, 107 with 9 deaths (8.5 per cent.).

Of the 125 cases in which conservative treatment was employed, gauze pack or drainage was done 115 times, with sixteen deaths; suture of the renal wound or wounds was done ten times, with no fatality.

The decision between expectant and operative treatment is a momentous one, as the fate of the patient often rests on this decision. Concerning the former Neilson says:

> So-called expectant treatment is permissible only in cases in which the local symptoms are insignificant, constitutional symptoms absent, and slight hematuria alone directs attention to the probability of renal injury.

Yet there are many severely damaged kidneys which if left alone, will cause death or prolonged illness, and in which the local symptoms are insignificant, the constitutional symptoms absent, and with but slight hematuria. There may be no differential sign or symptom between slight injury and complete rupture; therefore it would seem advisable to expose the kidney and arrive at a positive determination as to the extent of the injury in every case in which we can arrive at a probable diagnosis of injury of the kidney, and not guess at the seriousness or the triviality of the injury. By so doing a certain number of unnecessary exposures of the kidney will be made, but, on the other hand, a certain number of deaths will be prevented, and many prolonged illnesses and unsatisfactory results will be substituted by prompt and satisfactory recovery. As it is, in certain cases, impossible to separate the slight from the extensive injury it behooves one to treat all cases as though they were serious until they have been proved to be otherwise.

All operations for rupture must be exploratory at the onset, and may then be either radical or conservative. Nephrectomy has, in the past, been employed quite extensively; but, from a theoretical point of view, from the experiments of Dolgoff,[5] who found that severe laceration, even tearing the organ in halves, in dogs, did not result fatally; and from the clinical evidence, in the frequent, satisfactory recovery after conservative measures, it would seem that packing, draining or suture might be more frequently substituted for nephrectomy. Gauze packing or drainage is the most common method of conserving damaged kidney, being employed 115 times in 125 cases in which conservation was attempted. Primary suture has been performed on but few occasions, though it is the ideal method of dealing with such injuries. Watson was able to collect reports of eight cases, and Neilson added two that were treated in this manner. Since the report of the latter I have been able to find reports of three additional cases in the literature, which, with the case reported in this contribution, makes a total of fourteen. In these fourteen cases there was no death, and only two unsatisfactory results. In one (Delbet) a secondary nephrectomy was necessary, and in the second (Watson) a pseudo-hydronephrosis and fistula resulted.

In every case the sutures, when placed, caused satisfactory hemostasis. In one of Griffith's cases, that of a man aged 48, the mattress sutures pulled through the very friable organ, and the fibrofatty capsule was sutured enclosing the kidney as in a bag, with a satisfactory outcome. Dolgoff found that wounds of the kidney healed much more rapidly if the capsule was preserved, and especially if its cut edges were united. In my own case the capsule of the upper third of the organ could not be united, yet the result was entirely satisfactory. In this case the wound was closed with interrupted mattress stitches that passed deeply into the parenchyma, and the wound margins were then accurately coapted by over-and-over superficial stitches.

In Fredet's case the patient had a nephritis, and it was for this reason that nephrectomy was not done. As a consequence of the most encouraging result in this case Fredet, in his enthusiasm, says: "Nephrectomy is indicated as a late operation only where there is widespread infection."

REPORTS OF OTHER CASES

A synopsis of cases collected from the literature since Neilson's article is given below:

Griffith: A man aged 22, while running, slipped and fell, striking the left side below the ribs against the sharp edge of a piece of coal. He was able to walk some distance and climb two ladders, felt generally bad, but had no particular pain in the side. Five minutes after the injury he urinated what seemed to be pure blood, after which he felt much worse and nearly fainted. On admission to hospital he complained of pain all over the abdomen but more especially in the left lumbar region. One and three quarter hours after admission, the kidney was delivered through an oblique lumbar incision and was found to be torn on its posterior aspect at about the middle, extending from the convex surface to the hilum. Suture of the wound with catgut was done, which controlled the hemorrhage; a gauze wick was inserted to the kidney and the lumbar wound closed. The patient was discharged, well, on the eighteenth day.

Griffith: A man aged 48, was struck on the left loin by one end of a heavy timber. On admission to the hospital shortly after the injury the patient was in a kneeling posture, being unable to either sit or lie down because of the intense pain. The pulse was good, but there was vomiting of bile, tenderness and dulness in the region of the kidney, with hematuria. Exploration revealed the lower third of the kidney nearly detached, with a longitudinal tear extending along the mid-line of the convex surface of the upper portion. Mattress sutures were inserted to close the wounds, but many of them cut through the abnormally friable organ. The fibrofatty capsule was then sutured, enclosing the kidney as in a bag. The lumbar wound was closed with a tube drain reaching to the capsule. The patient was discharged, well, on the twenty-third day.

Fredet: A male was struck in the left flank by a heavy falling body; there was brief loss of consciousness, followed by severe pain in left side with a hematoma but no free fluid in the peritoneal cavity. Catheterization revealed hematuria. Exploration revealed lesions on the anterior and posterior surfaces of the kidney. Nephrectomy was thought to be indicated but because of a nephritis, it was deemed safer to suture the tears in the organ. Recovery ensued.

CONCLUSIONS

1. Owing to the rapid recent increase in the numbe of reported cases, there is reason to believe that subparietal rupture of the kidney is more frequent tha the literature would lead one to believe.

2. Shock, injury to other organs, and external evidence of trauma are frequently absent.

3. A history of an abdominal contusion, followed b rigidity and hematuria, is sufficient data to lead to a exposure of the organ.

4. Slight lesions, and complete rupture of the kidne can not be differentiated by clinical signs or symptom

5. Proof that there is an absence of serious rupture i called for before instituting the so-called expecta treatment.

6. Nephrectomy should be reserved for very extensi disintegration of the organ.

7. Conservative treatment, preferably by suture, indicated in the majority of cases.

123 Main Street.

THE ADENOID AND TONSIL OPERATION

JOHN EDWIN RHODES, M.D.

CHICAGO

The general practitioner first comes in contact wit the child, and on him must largely rest the responsibi ity of recognizing the symptoms of these conditions they appear in extreme cases. He should, moreove appreciate the fact that there are remote and often les pronounced symptoms connected with the adenoid an tonsil *question* that are as much a menace to the healt as the others. It is not difficult to decide that a chil who presents very large tonsils and adenoids and w breathes with open mouth, vacant expression, etc., shoul have an operation that removes the mechanical obstru tion to a normal breath-way. But there are many cas in which the mere mechanical obstruction is the lea important of the considerations involved, and the dec sion must often be based on symptoms not direct connected with the nose and throat, and which we a coming to recognize more and more fully as prop subjects for the operation, involving as much for t child's future as the other. In adults, too, we are now removing the tonsils frequently for far more important reasons than that they are large, and at times in cases in which, though very little tonsillar structure is visible on casual inspection, much is found to be imbedded in the tonsillar triangle.

---

[5] Dolgoff: New York Med. Jour., 1900, lxxii, 871.

* Read at a meeting of the Southside Branch of the Chicag Medical Society, Dec. 13, 1910.

I shall not attempt to speak extensively of the anatomic features of this subject. It must be recognized that tonsils when they are diseased form a culture medium for bacteria, and the pathogenic germs often enter the system. Rheumatic fever, myocarditis, endocarditis, nephritis, arthritis and arthritis deformans, adenitis and other conditions and infections are thus traced to the tonsil as the primary focus in many cases. The cicatrized tonsil, the result of chronic inflammation, often giving rise to peritonsillar abscess, should be mentioned in this connection.

The faucial tonsils and the pharyngeal tonsil are a part of the so-called Waldeyer's ring, draining into the secondary lymphatic ring; the faucial tonsil drains into those glands situate at the angle of the jaw, in front of the sternocleidomastoid muscle, and the hyoid; the pharyngeal tonsil drains directly into the retropharyngeal glands. These connections will explain very definitely the close relationship and frequent involvement of these glands in diseases of the lymphoid structures. It should be a routine practice to examine the glands at the angle of the jaw and along the border of the sternocleidomastoid in every case brought to us for treatment of the tonsils. It is surprising in what a large number of cases the infection has traveled that far, with a resulting enlargement of the glands. The manifest treatment should then be directed, of course, not to the gland primarily, but to the infecting tonsil, and yet in many cases the latter have not been the subject of concern by patient or friends. In these cases until the tonsils are removed other treatment is practically useless.

The pharyngeal tonsil is a mass of lymphoid tissue lying in the vault of the nasopharynx, and its upper, posterior wall; a mass somewhat lobulated longitudinally with a marked median recess, when markedly enlarged, and extending laterally into the fossæ of Rosenmüller. In addition to this there is sometimes found a mass of lymphoid tissue called the tubal tonsil on the posterior upper lip of the Eustachian cushion, and very often bands of tissue extend from this across the fossa. Scattered masses of lymphoid tissue are often seen also over the pharyngeal wall, extending down over the oropharynx. This condition of the pharynx is often indicative of the presence of adenoids, especially if the faucial tonsils are also enlarged. In some extreme cases, I have found masses of the lymphoid tissue extending down from the Eustachian eminence over the upper surface of the veil of the palate for a considerable distance. In such cases, manifestly, the curette could not complete an operation.

Rarely is it possible to make a satisfactory examination of the child's nasopharynx with the rhinoscope mirror. Occasionally a child, tractable and unafraid, will allow the tongue to be depressed and the small mirror to be carried to the pharyngeal wall, when a complete view of the nasopharynx is sometimes possible. Ordinarily, however, palpation is necessary and will give the information needed.

I prefer to have the child held on the lap of the nurse, arms and feet confined by the nurse, the head of the child against the shoulder and steadied by an assistant standing behind. The examiner then seats himself in front of the child. A gag is inserted in the left side of the child's mouth and held by the examiner's right hand while the clean index-finger of the left, previously oiled, is carried up behind the palate into the vault.

The nasopharynx of very young children can be examined in this way, and one sometimes finds adenoids in children as young as three or six months which need an operation when interfering with the nourishment of the child.

Another method equally good is to have the child on the left side of the examiner sitting in the lap of the nurse, or in a chair; then the head, grasped with the open left hand, is held firmly against the left side of the examiner, the fingers are placed under the ramus of the jaw, the thumb pressed against the cheek, carrying it between the teeth, thus forcing open the mouth, and preventing the child from closing it on the examiner's fingers. The first finger of the right hand is then easily slipped behind the uvula and up into the nasopharynx. This can be done gently and quickly, but seldom without causing the child fright and some bleeding, as the lymphoid mass in young children is friable, soft, and easily injured. Cocainization of the nasopharynx is sometimes desirable, but usually unnecessary. In very young children it is better to use the little finger for palpation.

Hypertrophied faucial tonsils are easily recognized. Lying between the anterior pillar (the palatoglossus muscle) and the much thicker posterior pillar (the palatopharyngeus muscle) is the triangular tonsillar area. It is divided by the plica triangularis, a thin sheet of mucous membrane passing from the upper third of the anterior pillar downward and backward to the posterior pillar. This plica is the usual antero-inferior limitation of the lymphoid tissue of the tonsil and is adherent to the surface of the tonsil. In simple hypertrophy, in children especially, it is often fused in the tonsillar mass in which the enlarged tonsil occupies not only the space inclosed by the plica, and anterior and posterior pillar, but that below the plica—an inferior lobe—reaching at times the border of the base of the tongue. In projecting tonsils the enlargement may be inward, a large mass extending quite to the median line of either side, or the mass may be broadened from before backward and above downward but projecting very little.

Another variety, often encountered in practice, is the imbedded form. The tonsil is generally confined to the supratonsillar fossa, or it may include almost the entire triangular area. Such tonsils do not project into the throat on casual examination, but have enlarged outward, tonsils of considerable size being sometimes completely imbedded in the tissues of the lateral wall and soft palate. By palpation, a method that should always be employed, it is often found as a distinct mass as large as a filbert, or larger, entirely hidden in these tissues. Such tonsils can be recognized often by causing the patient to retch, when the muscular action projects them into the fauces. At other times a blunt hook can be used to pull forward and press outward the anterior pillar, when they are brought plainly into view. This is the variety that is frequently found in the toxic conditions spoken of, and when they are removed there may often be expressed from the crypts numerous masses of white, cheesy exudate.

These are the tonsils also overlooked by the practitioner until the infective results of their diseased condition have already been brought about. These are the tonsils, too, on which so many inadequate operations are done, leaving much of the lymphoid masses still in the fossæ to continue their ravages on distant structures through systemic absorption. This may be partly explained by the fact that the tonsils are considered an operative field by the most inexperienced, and to this fact nothing has contributed more than that remarkably ingenious instrument, the tonsillotome, so easily manipulated that it appeals at once to every tyro.

The tonsillotome is not an instrument for every case, and indeed a very limited number only are suitable for its use. In the somewhat pedunculated tonsils, projecting into the fauces and easily engaged in the fenestrum of the instrument, a good operation can sometimes be done easily and swiftly. In other cases the instrument is an excellent one to cut off an enucleated tonsil which has been grasped and drawn inward by suitable vulsellum forceps. The ease of manipulation of the instrument and the idea once prevalent that a tonsillotomy was an all-sufficient operation in any case, has led to the universal use of the instrument. Our ideas, as specialists, have changed, and the instrument has been relegated to its proper position, for carefully selected cases only. It is not possible where the major portion of an imbedded tonsil lies submerged in the triangular fossa to do a proper enucleation with a tonsillotome alone, and to attempt to do it with this instrument is poor surgery, and not for the best interest of our patients. I condemn the practice because of these facts, and because it is possible to do an operation, in nearly every case, that is adequate and surgically right.

Let me preface my remarks on the method I follow with the statement that I have no particular instrumentarium to recommend for the use of others. Every operator has one to which he is accustomed. Every man should work with the tools he likes best, but I should insist that, if the operation is indicated, one should be satisfied with nothing less than the complete excision of the tonsil with its underlying capsule and the removal of every vestige of the adenoids in the nasopharynx, as far as possible. However, the matter of whether tonsillotomy is or is not advisable in some cases is one on which there has been, and is now, much debate, and one in which I should not care to be arbiter. It seems to me, however, that if the removal of the tonsils is indicated for any other reason than that they are a mechanical obstruction, the operation should include the crypts of the mass, which usually reach the underlying capsule, and therefore there should be a complete enucleation.

TECHNIC

The child should be in the hospital, if possible, the night before the operation, in order that it may become accustomed to the surroundings, and have the advantage of a night's rest.

I think it is not essential to precede the operation with any local treatments by antiseptics, although a mouth-wash and a nasal douche in the morning may be used.

Ether is the anesthetic for which no adequate substitute has been found. Since the investigation of Dr. Hinkle, given in a paper before the American Laryngological Association a few years ago, and of other writers, many specialists in this country have given up the use of chloroform and rely entirely on ether. I ve used some of the shorter anesthesias, but have not en pleased with them, and prefer ether, as a rule. Nitrous oxid with oxygen is safe, and can be prolonged almost indefinitely, but, since administration is so much interfered with by the operation itself and the profuse bleeding, it cannot be satisfactorily administered continuously and in these cases the period of unconsciousness is of too short duration, while relaxation is not as complete as with ether. The final stages of the operation, therefore, are apt to be performed on a struggling, semiconscious child, even when employed for adenoids alone. The same may be said of ethyl chlorid and ethyl bromid, although the effects of these are rather more prolonged. The child should be quite profoundly anesthetized, so that the subsequent operation need not be too much delayed by further use of the anesthetic.

There is no better point than this at which to insist that an adequate tonsil operation is often by no means an easy task. It should be done under a general anesthetic, in children up to 15 years of age, certainly; and in certain circumstances in adults. In adults, however, I prefer local anesthesia—of which I shall speak presently—if the patient has a little courage and can control the reflexes of the tongue and pharynx sufficiently not to interfere with the necessary surgical manipulation.

For illumination I use the Jansen photophore (an electric head-lamp), and therefore prefer to operate in a darkened room. I have the child placed in a partially prone position on the operating table, the left arm drawn backward under the body, the right shoulder being pulled backward by the assistant, to whom is entrusted the holding of the gag, which is placed in the right side of the mouth. I prefer the Allingham gag. The child's face is brought to the edge of the table, and underneath the head a Kelly pad may be placed, all pillows being removed. The gag is very apt to slip out of position unless held firmly, and the assistant should be cautioned regarding it. In this position there is no danger of blood reaching the larynx and trachea, and there need be no change of position in removing both tonsils and adenoids.

It seems to me that one of the most important steps in the operation is the adequate enucleation of the tonsil. To accomplish this a sharp knife, bent on the flat, is placed behind the anterior pillar, cutting from above downward, through the mucous membrane reflected from the tonsil to the posterior surface of the pillar or severing adhesions when they exist. In children, always, and sometimes in adults, as a rule I cut through the pliça triangularis, severing it from the attachment to the pillar. In adults it is sometimes possible to save this sheet of mucous membrane by passing the knife from above downward and backward between it and the tonsil, the under surface of which it covers. Then the velar lobe may be freed from its attachment to the posterior pillar in the upper angle, in the same way. The latter is not often necessary in a child. A hook knife may be necessary, too, for freeing the very upper angle, the tonsil being seized with a vulsellum forceps and drawn inward. This is seldom needed. After these attachments have been properly freed, a surgically clean finger is passed around the tonsillar mass, firmly, enucleating it still more from before backwards by lifting the mass with its underlying capsule from its bed on the superior constrictor muscle, as far as possible. Some force is sometimes needed in passing the finger between the anterior pillar and the tonsil and underneath the tonsil. I believe that this complete enucleation is a most important part of the operation, as was well emphasized by Shurly in the last meeting of the A. M. A. at St. Louis.

The tonsil is then seized with an Ingals tonsil forceps and drawn inward with slight force. It is often seen almost completely everted. Over the handles of the forceps a wire loop is then carried, and over the head of the instrument to its base, and the loop is then tightened. Great care should be taken here not to include the uvula in the loop of the snare. I cut the tonsil off rapidly with this cold wire snare in children, as it is quite friable. In older children and adults the loop is closed slowly as it crushes through the tonsil. In adults it is so fibrous that the milled wheel of the snare will have to be used to sever it. Indeed, a larger wire than a No. 5 piano wire, which I ordinarily use, may be needed and a more powerful instrument than the one I generally employ (the Bosworth snare, modified).

The lower tonsil, the left, is removed first, then the right. The Rhodes punch forceps may be needed, if small masses of lymphoid tissue remain in the triangle, and these are easily recognized and can be carefully picked out. The space can be well exposed with a small, long-stem double tenaculum and thorough examination made.

Bleeding should always be controlled before the adenoids are removed. Usually pressure with small sponges attached to uterine hemostatic forceps is all that is necessary. I always have ready a pair of Jackson hemostatic forceps and a Mikulicz clamp. In some cases a ligature may be passed over the Jackson forceps and the bleeding vessel ligated. Seldom is this necessary.

In the removal of the adenoids I find the Lowenberg forceps the most satisfactory, as the finger of the left hand may be held in the nasopharynx and the tissue removed can be controlled absolutely. I usually reinforce this by passing a Gottstein curette to remove small vestiges of lymphoid tissue on the upper and posterior wall. I have at hand also Freer's pernasal forceps to remove small masses in the fossæ of Rosenmüller or other portions of the vault. Bleeding is of course very free at this time, but ceases in a very short time. Sometimes it may be necessary to carry a sponge into the vault with a finger of the left hand and use pressure for a brief time.

The child is then placed in bed for a few hours, a light diet is recommended for four days, and the patient kept in the house for a week. Twenty-four hours in the hospital is usually sufficient. A gargle of 1 per cent. solution of phenol may be used every hour for two or three days, and less frequently for a week. Iodole may be insufflated through the nose three or four times a day.

I have found the method described one that is adequate for every kind and size of tonsil, and is radical. I believe, too, that there is much less danger of hemorrhage in the snare operation, although bleeding sometimes takes place, whatever method is used, and one must always be prepared for such an emergency.

Local anesthesia may be used for adults, but one cannot promise absolute freedom from pain and discomfort, although I have sometimes removed the tonsils with scarcely any. If it were perfectly safe to use injections of cocain and adrenalin this would be quite ideal. I have used the method a good many times. Reports of cases of death following such injections were made at the last session of the American Medical Association at St. Louis, and I should hesitate to recommend it as a routine practice. On the other hand, the use of adrenalin (1/1000) swabbed over the surface of the tonsil and pillars, followed by the local application of a 10 per cent. solution of cocain freely, or the powdered crystals of cocain have had no fatalities so far as I know. When injections are made, a 1 or 2 per cent. solution of cocain is made, to a dram of which 5 to 10 minims of a 1/1000 solution of epinephrin, adrenalin or suprarenalin (fresh) may be added. The injection should be carried deeply into the base of the tonsils along the line of the anterior pillar, about ½ inch from the border of the pillar, using 10 to 15 minims of the solution for each tonsil. I now use local applications, usually of cocain crystals alone.

The instruments employed are a tonsil separator, curved tonsil knives, for each tonsil, a hook-shaped knife for the disengaging of the velar lobe, vulsellum forceps (Casselberry's), tongue depressor, sponges, etc. I favor seizing the tonsil with the vulsellum forceps first and then dissecting. A Freer right-angle knife is passed deeply into the tissues between the anterior pillar and the tonsil and brought down along the posterior edge of the upper posterior surface of the plica triangularis, saving this intact, which can be done in many instances. I believe, however, we will get better results usually if this plica is removed also. The same procedure is carried through with the separation of the posterior pillar and the tonsil, care being taken not to cut into either pillar. While the assistant depresses the tongue, traction is made on the partially separated tonsil and the hook-knife is carried over the top of the tonsil, almost at right-angles to it at first and separation of the tonsil from above downward, with the underlying portion of the capsule, is begun. As soon as the velar lobe is free, the remainder of the separation can be done with the Freer flat knives, care and discretion being used so as not to remove any of the underlying muscular tissue of the superior constrictor, on which the tonsil lies. The cutting should then be done downward and inward toward the fauces. The operation is often comparatively painless, with moderate hemorrhage. This same operation may be done equally satisfactorily under ether.

In this article I have given the details, as briefly as possible, of a method that has proved very satisfactory in a large number of cases. While the technic is rather difficult, at first, it can be acquired, and the results are usually so good that the painstaking care is justified. It enables one to deal with every form of tonsil, and leaves the throat in a surgically satisfactory condition.

Peoples Gas Building.

Elbow Sign of Scarlet Fever.—C. Pastia, in the *Tribune Médicale*, states that he found the characteristic sign he describes in 94 out of 100 scarlet fever patients in Grosovici's service at Bucharest and in all of twenty-three scarlet fever children examined in Paris. The sign is an exanthematous, linear, continuous eruption, localized in the bend of the elbow and very intense. At first the eruption is pink, then it turns a deep red or "dregs-of-wine" color or may resemble ecchymosis. The linear eruption is generally single but there may be several lines in some cases; between them the eruption resembles that of the ordinary scarlatinal exanthem. This linear exanthem develops early, he says, and persists to the end of the general eruption, leaving a pigmented line as it subsides. It is often useful for differentiation of the disease when the general exanthem is too faint to be positively recognized or is already past. He has never found it in any other eruptive diseases.

THE PRESERVATION OF ANATOMIC DISSECTIONS WITH PERMANENT COLOR OF MUSCLES, VESSELS AND ORGANS

A SUPPLEMENTARY NOTE

EDMOND SOUCHON, M.D.
Professor Emeritus of Anatomy, Tulane University
NEW ORLEANS

This supplementary note is to record the changes and improvements in the method described in the preliminary note published in The Journal (Aug. 22, 1908, p. 642).

Certain subjects only will secure the color by the embalming solution and the method. They are cadavers whose muscles are of a dark color before being embalmed. This is determined before the embalming by making a long and deep incision (3 inches by 1) into the deltoid or the femoral vastus externus. If the muscles show a black cherry color, the preparations will present a satisfactory color. If the muscles show a deep red cherry color, they may make good preparations, but not so surely. If the muscles show a light red cherry the color of the muscles in the preparation will not be satisfactory and no ultimate treatment or procedure will improve it. The embalming solution and the method preserve the color that the muscles present in the subject, but will not give a dark color to muscles which present a light color in the subject before embalming. As a rule, negroes present blacker muscles than white subjects. It took a great deal of time and labor to find out these important facts.

I have finally reached the conclusion that the following steps are the best to produce satisfactory results. They are somewhat different from the ones described previously.

1. Use only lean male subjects. Fat, however small in quantity, makes bad preparations.

2. Embalm the subjects with the following formula:

A: Arsenious acid (saturated solution) 2.5 gallons; nitrate of potash, 1 pound; liquor formaldehydi 6 ounces. B: Alcohol, 16 ounces; liquefied phenol (carbolic acid), 6 ounces; glycerin, 16 ounces; creosote (beechwood), 2 ounces. The two solutions, B and A, must be mixed and strained. The proper color may show only a few days after the embalming. Articulations and visceral preparations should be dissected without delay.

3. The arteries and the veins may now be injected, if desired.

4. Now partition the subject off, that is, divide it into a number of pieces according to the preparations that it is desired to make.

5. Place each piece in a glass jar with a solution of 1 ounce of liquefied phenol to the gallon of water (C 1; see previous article).

6. Then place the specimen in an empty jar with a lid, and leave it to drain. Hang with hands and feet up. The draining requires about ten to fifteen days. Visceral preparations should not be allowed to drain more than two or three days.

7. When the dissection is completed the preparation should be placed in a jar containing a solution of 1 ounce of liquefied phenol to 1 gallon of filtered water (C 1).

8. When the dissection has ceased to purge it is placed in an empty glass jar with a lid on and is left to cure. Visceral preparations should not be cured.

9. The arteries must be painted with a vermilion red, and the veins with cobalt blue. The moist (gouache) colors are good. They should be allowed to dry thoroughly before the dissection is placed in the first solution. This drying requires fifteen to twenty hours. Experiments seem to indicate that the ordinary house-paints prepared ready for use have the advantage of doing away with these long hours of drying. The vessels to be painted with oil paints should be well mopped with cheese-cloth or absorbent gauze, and left exposed to the air for about two hours. They are then dry enough for the oil paint to take or stick. Two thin coats are better than a single thick coat. After the painting is done, leave the vessels exposed to the air for about two hours; then place them in the permanent solution.

10. Finally, the preparation is placed in a glass jar filled with a solution of 20 ounces of alcohol to every gallon of filtered or distilled water (A 20; see previous article). Visceral preparations, brains, and articulations and ligaments seem to do better in a solution composed of 20 ounces of alcohol and 1 ounce of liquor formaldehydi to the gallon of water (A 20 F 1; see previous article). The alcohol seems to prevent the snow-white bleaching action of the formaldehyd and the formaldehyd the ivory bleaching action of the alcohol.

11. The solutions should be changed as soon and as often as they become slightly cloudy or discolored. The refraction of the water has often a very marked effect in reducing the intensity of the dark brown color which the muscles present when they are out of the solution. If this could be remedied, it would be a great improvement.

I have experimented extensively with solutions of glycerin by immersing in them preparations without proper color to improve their color. It did have that result, but as soon as the preparations were placed in A 20 or any other solution the improved color disappeared and the original unsatisfactory color returned. Instead of placing these preparations in A 20 I placed them, after the curing, in paraffin oil or ordinary white petroleum oil and the improved color remained, but after awhile the oil became cloudy.

Attempts were made to paint muscles with bad color. Moist colors (brown madder) gave a good result, but in course of time the color fades. Oil paints stand better, but at close range they do not look natural.

On being removed the brain should be placed in a solution composed of 1 ounce of liquor formaldehydi and 20 ounces of alcohol to 1 gallon of water (A 20, F1). The solution must be changed as soon and as often as it becomes discolored by the blood. Preparations of the brain which require dissections should be made before the brain hardens too much. Those preparations which require only sections should be done when the brain has hardened.

2403 St. Charles Avenue.

TYPHOID MENINGITIS

V. C. DAVID, M.D., and F. A. SPEIK, M.D.
CHICAGO

Clinically and pathologically typhoid meningitis is of especial interest, because of the common occurrence of nervous symptoms during the course of a severe typhoid, and because of the several types of meningitis that occasionally occur. R. Cole[1] has critically reviewed the subject of typhoid meningitis, adding a number of new cases to a list based on bacteriologic findings. He divides the cases into three groups:

1. Meningism. Symptoms of meningitis are present but there are no meningeal lesions and no direct relation between the bacteria and the symptoms. This condition is produced by the toxins in other specific fevers.

2. Serous meningitis of Quincke, in which there are symptoms of meningitis; the brain shows, microscopically, edema and round-cell infiltration, and a serous

---

[1] Johns Hopkins Hosp. Rep., 1904, v, 12.

exudate is present, in which is found the typhoid organism.

3. Suppurative or purulent typhoid meningitis.

For purposes of more definite classification we prefer to subdivide Class 3 into purulent typhoid meningitis with and without intestinal lesions.

The difference in symptoms between a severe typhoid with marked nervous symptoms and meningism is very slight in many cases, and of degree only. Muscular twitchings, severe headache, delirium, carphologia, stiff neck and occasional presence of Kernig's sign are seen in many typhoids, without special features. A step further and the presence of palsies, convulsions, eye lesions and vomiting makes the diagnosis of meningism or meningitis, depending on the cellular and bacterial content of the cerebrospinal fluid. A differential diagnosis between meningism and serous meningitis is made by the presence of the typhoid bacillus in the cerebrospinal fluid of the latter. Is this sufficient evidence? Is it not possible that the typhoid bacillus occurs in the cerebrospinal fluid during the course of a fair proportion of typhoids, just as it is found in the urine, gallbladder and blood in many cases? If the typhoid bacillus is present in the cerebrospinal fluid as part of a general distribution of the organism, we must assume that in many cases it produces very few, if any, symptoms and no pathologic changes; and in other cases that it produces marked symptoms and no pathologic changes; and again, marked symptoms and definite lesions of meningitis. We have studied the cerebrospinal fluid from twelve patients with typhoid fever of varying severity with a view of determining the bacteriologic content and the possible therapeutic benefit to be derived from lumbar puncture in cases with marked nervous symptoms.

FINDINGS IN CEREBROSPINAL FLUID OF TWELVE PATIENTS WITH TYPHOID FEVER

Severity of Case.	Drops per Minute.	Color of Fluid.	Therapeutic Effect.	Culture.
1. Average	118	Clear	None	Negative.
2. Average	32	Clear	None	Negative.
3. Average	Increased pressure	Clear	None	Negative.
4. Average	Increased pressure	Clear	None	Negative.
5. Mildly nervous	104	Clear	None	Negative.
6. Mildly nervous	Increased pressure	Clear	None	Negative.
7. Nervous	80	Clear	None	Negative.
8. Nervous	?	Clear	None	Negative.
9. Nervous	190	Clear	None	Negative.
10. Nervous	Stream	Clear	None	Negative.
11. Nervous	Stream	Clear	None	Negative.
12. Nervous	Stream	Clear	None	Negative.

Cultures were made from the cerebrospinal fluid on bouillon and slant agar. To a large tube of bouillon about 7 or 8 c.c. of cerebrospinal fluid were added and about 1 c.c. on slant agar. The cultures gave no typhoid growth in any of the twelve cases. Two tubes showed a growth of staphylococcus, which was probably a contamination, as the cases were complicated by furunculosis, and by a bed-sore in one instance. In the six nervous cases, delirium, carphologia, involuntary discharges, and, in one case, stiff neck were present, and in none of them was positive improvement noted after lumbar puncture. In all cases, after the fluid necessary for cultures was withdrawn, the fluid was allowed to escape until it came to about twenty drops a minute. None of the cases showed any unfavorable symptoms after the lumbar puncture. The pressure under which the fluid escaped was almost uniformly increased in the very nervous cases. The cases were all typhoid fever as determined by the presence of a positive agglutination test, or a positive blood-culture. They were in the second to the fourth week of the disease.

Rocaz and Carles[2] report eight cases of typhoid fever in children from 4 to 12 years old, in all of whom the classical symptoms of meningitis, including Kernig's sign, strabismus and irregular pupils, were present. Lumbar puncture showed an increase in tension of the cerebrospinal fluid in all of the cases. In two cases there were a number of lymphocytes in the fluid, but in the remaining six cellular elements were lacking. Cultures from the fluid were all sterile. A marked improvement followed spinal puncture in all of the cases. The authors divide the contents of the cerebrospinal fluid of meningeal typhoids into four classes: A. Containing pus, typhoid bacilli alone, or, at times, other organisms. B. Colorless fluid containing the typhoid bacilli. C. Clear fluid with abnormal cell content, as excess of lymphocytes. D. Normal fluid but under high tension. R. Stein[3] also reports three cases with symptoms of meningitis in the course of typhoid fever in which lumbar puncture revealed a sterile fluid. Improvement followed the withdrawal of the fluid.

Under the head of serous typhoid meningitis Cole reported eight cases from the literature and added five more of his own. The interesting points are brought out that in one case recovery occurred and in several others the meningeal symptoms cleared up, the fatal issue being due to other causes. The time of the onset of the meningeal symptoms was variable and in severe cases the symptoms differed only in degree from those of a severe typhoid. In other cases the symptoms of meningitis were classical. Since Cole's paper cases of serous typhoid meningitis have been reported by Nieter,[4] A. Schutse,[5] Sicard,[6] and E. H. M. Milligan.[7]

We wish to report a case of serous meningitis occuring in a typhoid patient during the fourth to fifth week of the disease, from whose cerebrospinal fluid a motile bacillus was recovered which was agglutinated by the patient's serum, which previously had agglutinated known typhoid bacilli.

CASE 1.—*History.*—P. Y., a middle-aged Austrian laborer, entered Cook County Hospital, September 29, 1909, on the service of Drs. Kerr and Elliot, with a diagnosis of typhoid fever. He gave a history of the usual prodromes of typhoid.

Examination.—On admittance the patient had rapid respirations and flushed face. His spleen was palpable and some abdominal tenderness was elicited; lungs, heart and reflexes seemed normal; temperature was 104, pulse 112, and respirations 28. The urine was acid, specific gravity 1.020, negative for sugar but positive for albumin, and microscopically hyalin and granular casts were found. The white blood-count was 3,500 and agglutination of typhoid bacilli was positive in fifteen minutes in dilution of 1 to 50.

Course of Disease.—From September 30 to October 10 the patient had involuntary discharges, was drowsy and stupid

7. Brit. Med. Jour., 1908, i, 1295.

and occasionally irrational. The temperature ranged from 103 to 105.2 F. per rectum. October 5, examination revealed typical findings of consolidation in the right lower lobe. The respirations became 40. On October 11 the patient had a severe chill and complained of pain in the head and abdomen. On October 13 he had another chill, and examination showed his neck to be rigid and extended. The eyes and reflexes were normal. The Kernig sign was present on the next day, and rigidity of the neck and opisthotonos were marked. Lumbar puncture was made and a clear fluid escaped at a scant 6 drops a minute. Cellular elements in the fluid were few. Cultures from the fluid showed next day a motile bacillus, morphologically like *Bacillus typhosus*, which was agglutinated by the patient's serum in fifteen minutes in a dilution of 1 to 40. From this period the patient grew constantly worse and developed twitchings of the muscles and stupor, and died October 18. Unfortunately no autopsy was obtained.

In reviewing the literature on purulent typhoid meningitis Cole found many cases reported, but few bacteriologically proved. He cites fifteen authentic cases, all showing intestinal lesions. In these cases the onset was acute, beginning in the second or third week of the typhoid and lasting from two to seven days. They were all fatal. Kernig's sign was absent in two out of three cases. Netter has reported 313 uncomplicated typhoid cases with the Kernig sign present forty-four times. Since Cole's communication no other cases of purulent typhoid meningitis with intestinal lesions have been reported.

We wish to report a case in a 4-year-old girl, in whose cerebrospinal fluid typhoid bacilli were present during life, and at the autopsy, were isolated from the meninges, lateral ventricles and cord. Characteristic intestinal lesions were found at autopsy.

Case 2.—*History.*—Annie S., 4 years old, Belgian, entered Cook County Hospital, June 20, 1908, on the service of Drs. Abt and Butler. The history of her illness was unsatisfactory, but her parents had noticed that she had had fever, no appetite and had been extremely restless during the week previous to admission.

Examination.—The patient was a well-nourished but restless child with flushed face and sordes on the lips. The neck was not rigid, no herpes were visible and the tongue was dry and coated. The pupils were equal and reacted normally; heart beat 180, and lungs normal. The abdomen showed no rose spots, was not tympanitic, tender nor rigid; spleen was not palpated; knee-jerks were not elicited, neither was there any Kernig sign, ankle-clonus or Babinski sign. Temperature on entrance was 104 F, pulse 136, respirations 36. The white cells were 6,000 per cu. mm.

Course of Disease.—The next day the general symptoms improved. There was no agglutination in a dilution of 1 to 40. On June 24 the spleen was palpable and there was a positive diazo reaction in the urine, which was otherwise normal. The patient was very sick at this time and extremely restless, tossing about continuously. Leukocytes on June 29 were 9,500. On June 30 the patient's condition was very poor. She lay in a stupor with divergent strabismus and stertorous breathing. Heart and lungs were normal. There was still no rigidity in the neck and Kernig's sign and ankle-clonus were absent. The feet were in marked plantar flexion and a suggestion of a Babinski sign was present. Agglutination still was negative. In the evening there was a positive Kernig, rigid neck, opisthotonos, and the respirations were Cheyne-Stokes in character. The pupils were equal but reacted sluggishly to light. The next morning the pupils were unequal, the left being larger than the right, and twitching of the corrugator muscle was noticed over the left eye together with twitching of the left cheek and left hand. Opisthotonos was marked, the hands were in flexion and the back was board-like. The ears were normal. Temperature was 107 F.; pulse could not be counted. By lumbar puncture about seven drams of a turbid, opalescent fluid escaped under pressure. This fluid was secured in a sterile test-tube and cultures were immediately made in bouillon. A smear made of the fluid was found to contain equal numbers of polynuclear and mononuclear leukocytes and great numbers of short, thin bacilli, mostly extracellular. These organisms were Gram-positive. No tubercle bacilli were present. The patient died at 2:15 p. m.

Macroscopic Post-Mortem Findings.—Twenty-three hours later, the ileum and jejunum were found to be the seat of an extreme degree of ulcerative enteritis. In all there were forty ulcers, round or elliptical in shape, longitudinal to the axis of the bowel and occupying the position of Peyer's patches. The base of the ulcers in several instances was on the serosa. Almost all were in the stage of healing, and the shaven-beard appearance was frequently seen. There were no lesions in the duodenum, appendix or colon. On opening the skull cavity the dura was found adherent to the calvarium. On removing the dura a greenish-yellowish exudate was found filling the sulci and following the course of the vessels. At the base of the brain was found about two ounces of a cloudy flocculent exudate. The vessels of the brain were everywhere injected. Considerable bloody fluid was found in the lateral ventricles. The base and cortex of the brain seemed to be equally involved in the inflammatory process. On opening the dura of the cord a quantity of cloudy purulent fluid escaped. The vessels of the cord were prominent and injected. All levels of the cord were involved. The post-mortem diagnosis was: (1) acute purulent cerebrospinal leptomeningitis; (2) typhoid ulcerative enteritis; (3) acute splenitis; (4) mesenteric lymphadenitis; (5) right fibrous pleuritis; (6) passive hyperemia of the lungs and kidneys.

Microscopic Post-Mortem Findings.—Microscopically, different sections of the brain showed a thick cellular exudate over its surface, dipping down into the sulci. The blood-vessels on the surface of the brain were dilated and surrounded by thick masses of exudate, but in no place was the intima of the arteries lifted up by the cells of the exudate, as described by Ohlmacher in his case. In the walls of the vessels and in their proximity, especially, were seen large cells almost four times the size of a polynuclear cell, with vesicular, bladder-like nuclei. These cells were not observed to contain bacilli, which were numerous throughout the exudate. The cellular elements of the exudate varied in different places. In some areas the polynuclears numbered as high as 80 per cent., and in others the cells seemed to be mostly mononuclears. The large mononuclears were in preponderance. The brain membranes were almost exclusively involved in the inflammatory process as the brain substance itself seemed quite normal. The changes in the cord were similar to those described in the brain. The exudate seemed to be composed of polynuclear and mononuclear leukocytes and was especially marked about the anterior roots in the subdural space. There were also patches of extradural exudate and mononuclear cells were seen in the central canal of the cord.

Bacteriology.—Cultures made in bouillon from the cerebrospinal fluid during life showed a diffuse cloudy growth at the end of twenty-four hours. Hanging drop revealed motile bacilli with motion of the whirling, darting type. A smear from this culture showed many short thick-and-thin bacilli which were Gram-positive. Subcultures were made from the bouillon culture on the following media:

Agar Slant.	*Litmus Milk.*	*Potato*	*Glucose-Agar.*
24 Hours			
Slight, whitish, pearly growth.	Faint pink....	Faint dry line.	Deep growth; no gas.
48 Hours			
Only slightly increased growth.	Lilac pink.....	Moderate	No gas.......
6 Days			
Growth still localized.	Still lilac pink.	No odor; moderate.	No gas........

No indol in sugar-free bouillon.

With known typhoid blood this bacillus was agglutinated in a dilution of 1 to 40 inside of an hour.

At the autopsy cultures were made from the heart's blood, the pericardial fluid, bile, cerebrospinal canal, base of the brain, lateral ventricles and dura. Smears of these fluids, except the heart's blood and pericardial fluid, showed a short thick-and-thin bacillus. The typhoid bacillus was isolated in pure culture from the base and cortex of the brain, lateral ventricles and from the spinal cord. The colon bacillus was isolated from the bile. The typhoid bacilli, thus obtained, were agglutinated by the serum of a known typhoid.

Extremely interesting and somewhat rare are the cases of typhoid without intestinal lesions. Flexner and Harris[8] reported a case with an acute splenitis, with no intestinal lesions, in which typhoid bacilli were isolated from the spleen, lung and liver in pure culture. Opie and Bassett[9] report a similar case, clinically typhoid, with no intestinal lesions; but in which typhoid bacilli were found in the liver, gall-bladder and kidney. Neumann and Schaffer[10] report a case of suppurative meningitis, due to the typhoid bacillus, without intestinal lesions. Henry and Rosenberger[11] report a case of purulent typhoid meningitis with a bacteriemia, enlarged spleen and enteritis, but no ulceration of Peyer's patches. Southard and Richards[12] report a case of suppurative typhoid meningitis, in a tabo-paretic with bronchopneumonia, in whom there were no intestinal lesions, but typhoid bacilli were isolated from an enlarged mesenteric gland. R. S. Lavenson[13] reports a localized collection of pus in the pia arachnoid on the left and right cerebral hemispheres in a case from which typhoid bacilli were cultivated from the cerebrospinal fluid *intra vitam.* Smears from the pus at autopsy showed Gram-negative bacilli. The spleen was not enlarged and the intestines were normal.

We wish to report a case of suppurative typhoid meningitis with a bacteriemia without intestinal lesions, in which the typhoid bacillus was isolated from the cerebrospinal fluid during life and at autopsy.

Case 3.—*History.*—J. S., aged 48, entered the Cook County Hospital, Jan. 8, 1905, on the service of Drs. Preble and Reed. He was in a semiconscious condition.

Examination.—The temperature was 102 F. and pulse was 104. There was no enlargement of the spleen; reflexes were sluggish; leukocytes, 9,500 per cu. mm.

Course of Disease.—On the second day the patient had a convulsion which lasted ten minutes. Distinct nystagmus, vertical and horizontal, was present and the head and eyes were turned foward the right. On the third day he developed stiffness of the neck and legs and a lumbar puncture was made. A small amount of turbid fluid dropped out under no pressure. Smears of this showed an equal number of polynuclear and faintly staining mononuclear cells. A considerable number of organisms were present which were either diplococci or short bacilli in pairs. They were arranged in chains or pairs of four and were not intracellular, nor did they stain by Gram stain. Cultures were made from the spinal fluid as well as from the blood. In thirty-six hours these cultures showed a pure growth of a very short, thick bacillus, actively motile, Gram-negative, which grew culturally like *B. typhosus.* On the fifth day the eye-grounds were examined and found negative, but Kernig's sign was positive and the tongue protruded to the right. The nystagmus was less pronounced. Goose-flesh phenomenon was seen on the left side of the body, there being a sharp dividing line anteriorly and posteriorly. The patient was semicomatose; temperature 106.4 F. The patient died on the fifth day at 12:30 p. m.

Macroscopic Post-Mortem Findings.—The necropsy was held two days later by Dr. Reed. The anatomic diagnosis was purulent cerebrospinal leptomeningitis, chronic diffuse nephritis, atrophic cirrhosis of the liver, old depressed fracture of the skull, epigastric hernia, pulmonary congestion and edema.

The intestines were entirely normal. Peyer's patches were neither swollen nor ulcerated. The spleen weighed 280 gm. and had five notches. Its pulp was soft but the markings were quite distinct. On opening the skull cavity the dura was found adherent to depressed bone at the site of an old fracture. The meninges were much injected over the vertex, and above the Sylvian fissure was a fibropurulent exudate in the pia following the lines of the vessels on both sides and along the longitudinal fissure and temporal lobes. The exudate was more marked along the perforated spaces at the base of the brain, covering the pons and the region between the medulla and cerebellum and the upper surface of the cerebellum. In the lateral ventricles was a turbid, bloody fluid. The meninges of the cord were hyperemic in their whole extent, and beneath the meninges was a fibrinous exudate.

Microscopic Post-Mortem Findings.—Sections of the cord, occipital lobe and cerebellum were examined microscopically. In all there was a large amount of exudate on the meninges, composed mostly of polynuclear and large mononuclear cells This exudate was most intense around the veins and arteries and separated the meninges freely from the substance of the brain and cord. In no instance was the exudate present in the brain substance. In the sections studied there was not observed any lifting of the endothelium of the vessels by exudate. In the sections stained with methylene blue there were numerous bacilli seen, arranged in chains of three and four. No other organisms were seen.

Bacteriology.—Cultures were made at the autopsy by Dr. Stober. The *Staphylococcus albus* was grown from the pericardial fluid. The colon bacillus was isolated from the cord, cerebrospinal fluid, lateral ventricles and meninges of the brain. The typhoid bacillus was isolated from the cerebrospinal fluid and its identity made certain by subcultures, the description of which we omit. This organism was agglutinated by known typhoid serum in a dilution of 1 to 40 at the end of forty minutes.

SUMMARY

Typhoid bacilli are not found in the cerebrospinal fluid in uncomplicated cases of typhoid fever.

Typhoid patients suffering the ordinary nervous manifestations such as delirium, involuntary discharges, carphologia and severe headache are not benefited by withdrawal of cerebrospinal fluid, although the fluid may be under increased tension.

In typhoid patients showing classical symptoms of meningitis, the cerebrospinal fluid may be sterile, but lumbar puncture and withdrawal of fluid has improved the clinical condition in a striking way in some cases.

When typhoid fever patients show meningeal symptoms such as rigidity of the neck, Kernig's sign, convulsions, strabismus or irregularity of the pupils, lumbar puncture should always be done, and the fluid obtained examined bacteriologically and microscopically.

72 East Madison Street—5831 Washington Avenue.

Abdominal Pain and Loose Sacro-Iliac Joint.—There is one source of pain, and an important one which it behooves the surgeon always to be looking for, and that is the one due to loose sacro-iliac joint, first discovered, investigated and heralded by Joel E. Goldthwait of Boston (*Boston Med. and Surg. Jour.*, 1905, pp. 593, 643). This pain is apt to be associated with more or less severe backache, generally on one side over the sacro-iliac joint. It sometimes extends through to the front of the joint, where it is most apt to be mistaken for an affection of some pelvic organ. It can, as a rule, be demonstrated by a shortening of the affected leg and by rotating and forcing it strongly or by pulling it outward. In other instances the reasoning is more by exclusion. The therapeutic test is a valuable one, as most of these patients are relieved by a strong bandage made like a surcingle.—H. A. Kelly, in *Interstate Medical Journal.*

A CASE OF EPITHELIOMA OF THE VULVA AND A CASE OF RECURRENT GROWTH OF THE MEATUS URINARIUS TREATED BY IONIC SURGERY AND PLASTIC OPERATIONS*

G. BETTON MASSEY, M.D.
Attending Surgeon, American Oncologic Hospital
PHILADELPHIA

The case of epithelioma of the vulva is reported as presenting somewhat unusual features, and also as illustrating one type of malignant growth for which the ionic method of destructive sterilization is peculiarly adapted. The permanence of the result attained is fairly assured by the fact that nearly two and a half years have passed since the operation was performed. The salient points of this case were as follows:

Patient.—Miss E. Z., aged 49, was referred to me by Dr. Marie Formad, of Philadelphia, June 16, 1908.

History.—Four years ago a lump the size of a pea appeared on the right labium majus; it increased in area and ulcerated. Two years ago, Dr. Formad sent her to a hospital where a microscopic examination was made and the case pronounced inoperable. During the past two years the increase in the area of the growth has been rapid.

Examination.—The condition on admission to the Oncologic Hospital was as follows: An eroded and proliferated surface extended from the clitoris to a point below the anus, involving the whole vulvar area and extending some distance into the urethra, vagina and rectum. There was a characteristic discharge accompanied by a foul odor. No enlarged glands were discoverable. The blood-examination showed erythrocytes, 5,550,000; leukocytes, 5,800, and hemoglobin, 81 per cent.

Treatment.—On June 24, 1908, the patient was placed under ether and a major monopolar application of zinc-mercury ions was made with a current of from 1,000 to 1,200 milliamperes for one hour. This application was accomplished by the ionic dissolution of sixteen zinc needles, each heavily coated with quicksilver and inserted in the periphery of the growth. The needles were connected with the positive pole of the direct current, the negative being a large kaolin pad under the patient's back. On separation of the large mass of sterilized tissue two weeks later an immense cloaca-like opening was revealed, into which the three pelvic outlets coalesced, the cavity extending so far on the right as to expose the lower edge of the pubic ramus. The wound was painless, and filled in rapidly. By August 18 the patient had regained partial control of both rectum and bladder.

Subsequent History.—Four months after the operation the floor of the pelvis had become partially replaced by healthy scar tissue, though this tissue was insufficient to prevent a protrusion of the vaginal and rectal walls, the prolapsed anterior vaginal wall containing a cystocele and giving marked discomfort when the patient sneezed or laughed. Dr. Longenecker, of the hospital staff, kindly did a plastic operation at this time on the anterior vaginal wall, with excellent results.

Plastic Operation.—Ten months after the ionic operation the cicatrization was still incomplete at a central point around the urethral opening, this opening existing at about the middle point of the normal urethral length, the external portion having been involved in the disease and destroyed at the operation. It was decided that a plastic operation for covering the bare area would be tried, and this was done by Dr. Hewson, April 18, 1909, a square flap of skin and subdermic tissue being dissected from the left side of the scar and side of the thigh and transferred to the freshened surface, an opening having been made in the middle of the flap to correspond with the urethra. A soft catheter was placed securely in the partly artificial urethra thus made and kept in position for six days, leaving some vesical irritation.

Result.—At the present time, two years and five months since the ionic operation, there is no evidence of recurrence of the malignant growth, and the patient's only discomfort is due to the practical absence of the lower rectal sphincter, making it difficult to retain flatus, and permitting soiling of the clothing when the feces are unformed. The bladder retains some of the sensitiveness acquired at the time of the last plastic operation, and micturition is somewhat precipitant.

Examination of Growth.—A specimen of the tissue was removed just prior to the ionic operation and was reported on as follows by Dr. John M. Swan, the pathologist of the hospital:

"A piece of tissue from the vulva, submitted for examination: The specimen is composed of skin and subcutaneous tissue. The epidermis has grown down into the underlying connective tissues, where it forms irregular islands of epithelial cells surrounded by young connective tissue. The cells in the epithelial islands are squamous in type. There are no pearly bodies. Diagnosis: squamous-celled epithelioma of vulva."

The other case to which I invite attention is an illustration of the difficulties that sometimes surround the diagnosis of growths of the urethral orifice in women. The appearance presented by this growth when first seen was that of a typical caruncle, the bright red color of the round protuberance showing within the urethral orifice, and its exquisite tenderness, both indicating a benign neoplasm. Yet a measure of destructive sterilization adapted to such a diagnosis was followed by the recurrence of a distinctly malignant growth in the same situation a few months later. The successful destruction of this second manifestation of the growth by an ionic application fully adapted to the malignant conditions will illustrate also, I think, the value of this form of surgery in this situation, and the opportunity that it presents for conserving the unaffected urethral tissues.

Patient.—Miss F., aged 33, was referred to me by Dr. J. B. Shaw, of Trenton, N. J., May 12, 1909. Her father died of cancer of the liver, otherwise the family history was negative. During the past five years the patient had lost 35 pounds in weight, and for two years she had suffered from a burning sensation at the urethral opening, greatly aggravated by the passage of urine, and from a more constant soreness referred to the bladder, with considerable muco-purulent leukorrhea.

Examination.—The patient was rather thin and somewhat bronzed in color. Inspection revealed a bright red caruncle-like body the size of a pea projecting slightly from the meatus urinarius. It was smooth and excessively tender to the touch. On urethroscopic examination the caruncle could be traced as an elongation up the urethra about one inch, it being attached as a sessile growth to the right side of the urethral mucous membrane.

Treatment.—The patient was admitted to the Oncologic Hospital and placed under ether for ionic destruction of the growth May 13, 1909. After etherization, a specimen was removed for microscopic examination; this caused free hemorrhage, which was quickly arrested by placing a zinc-mercury needle in the wound and turning on from 30 to 40 milliamperes of the direct current, positive. The hemorrhage being controlled, another positive zinc-mercury needle was thrust into the base of the growth, and, with both needles active, the current was raised to 80 milliamperes and maintained at this strength until the whole of the growth appeared to be devitalized and white, the total duration of the application being sixteen minutes.

Result.—The patient required catheterizing for twenty-four hours, after which time urine was voided. There was no rise of temperature. The small slough separated one week later, and the patient was discharged from the hospital at the end of two weeks.

---

* Read before the Obstetrical Society of Philadelphia, Dec. 10

Examination of Growth.—The specimens removed were submitted to Dr. Swan, who made the following uncertain report, the cause of the uncertainty possibly being the failure to secure a portion of the base of the growth.

Pathologic Report on First Specimen.—"A few fragments of tissue removed from the external urinary meatus. The tissue is composed of a surface epithelium of the stratified squamous type lying on a connective tissue groundwork. The majority of the sections are of such a nature that no opinion can be given as to their character, but in one slide the connective tissue portion of the specimen is composed of a loose reticulum of cells of varying type mixed with an extensive exudate of red blood-corpuscles. Many of the cells, I believe, are epithelial cells, and I think the tumor is malignant, but I am not prepared to give an opinion as to its proper classification. Diagnosis: questionable."

Subsequent History.—The patient was kept under close observation, and seven months later (Dec. 13, 1909), there was distinct evidence of a recurrence of the growth in the shape of an ulceration at its site with raised, hard edges that refused to heal. She was readmitted to the hospital under the belief that the growth was originally and still malignant, with a view to its thorough destruction. On this occasion a current of 200 to 300 milliamperes was employed for double the previous time, or thirty-four minutes, and with six larger needles completely circling the growth at its base. Both operations were monopolar, that is, the negative pole was a large kaolin pad beneath the patient's back. Special efforts were made at this second operation to reach the highest point of the growth in the urethra with as little loss of muscular tissue as possible.

Pathologic Report on Second Specimen.—The pathologic report on the specimen removed at this time is as follows: "Three fragments of tissue removed near the orifice of the urethra, submitted for examination. The largest of these fragments is composed of very much hypertrophied squamous epithelium, which is in one place thrown into numerous folds so that it resembles the duct of a gland. Many of the cells of this epithelium are hydropic. No place can be found in which this epithelium extends into the underlying connective tissue, but the connective tissue just beneath it is the seat of a very well-marked round-celled infiltration, and these cells are principally of the plasma-cell type. The tissue is markedly congested, and in some places there is free hemorrhage. The round-celled infiltration above referred to is seen in scattered areas throughout the connective tissue, here and there associated with polymorphonuclear cells. There are a great many new blood-vessels in the tissue. One of the smaller bits is elliptical in outline, surrounded throughout its entire extent with a stratified squamous epithelium which does not dip down into the underlying connective tissue. This connective tissue is rich in blood-vessels, which are filled with blood, and shows numerous fibroblasts, and areas of small round-celled infiltration of the plasma cell type, mixed with lymphocytes. The third piece is composed of masses of round cells of varying type; polymorphonuclears, lymphocytes, plasma cells and fragmented nuclei. The tissue contains numerous blood-vessels with fairly thick walls. In several places there is free hemorrhage. In one part of this piece the endothelial cells forming the walls of the blood-vessels appear to be proliferating. Diagnosis: infective granuloma (?)."

Third Operation.—On Feb. 24, 1910, the patient was admitted a third time for the destruction of three nodules of bright color at the meatus. A current of from 100 to 150 milliamperes was used for twelve minutes, with three needles.

Result.—Her progress thereafter was steady, the parts closing in with tissue of normal color, somewhat retracted, but with complete control of the bladder and absence of unpleasant sensations, except a hypogastric discomfort for a time, apparently referable to the bladder. At present, ten months after the last operation, there is smooth scar tissue occupying the whole site of the growth, the external layer being regenerated mucous membrane by peripheral budding. The urethra seems healthy and of normal caliber, with the meatus retracted about one inch. This retraction has tilted the anterior wall of the vagina outward at the urethral orifice. The patient's unpleasant sensations on micturition have ceased and she has good control over the bladder. No evidence of a return of the disease can be found, and she has gained in weight and color.

903 Professional Building.

EARLY DIAGNOSIS OF GALL-STONE DISEASE

C. C. COLEMAN, M.D.
Instructor in Principles of Surgery and Clinical Surgery in the Medical College of Virginia
RICHMOND, VA.

The success of surgery of the bile-tract within the last ten years is due to more effective cooperation between the surgeon and the general practitioner, to closer observation of pathology, and to the contributions of experimental medicine. The opportunity of the surgeon to study pathology at the operating-table has brought about a clearer understanding of the significance of symptoms which heretofore have not been appreciated. The great work done by the Mayos and their associates, by Deaver, Moynihan and others, in calling attention to pathologic conditions found in the living has revolutionized our former conception of gall-stone disease. We now know that gall-stones, instead of being frequently present without symptoms, create a distinct type of clinical phenomena, which in the past we did not properly interpret. The picture of the terminal stage has been too frequently used for a general description of gall-stone disease.

The close association of the organs of the upper abdomen often causes diseases of any of these organs to find expression in the stomach. To assign these stomach symptoms to their real cause requires careful study. Except in ulcer or cancer, the stomach is seldom the seat of primary trouble, though it may be the agent through which distress in many abdominal organs may manifest itself.

The classical picture of gall-stone disease, accompanied by attacks of severe pain radiating to the right shoulder, nausea, vomiting and jaundice, is a late stage and results from complications that a calculous cholecystitis may cause. It is most unfortunate that these symptoms are still regarded by many as necessary to a diagnosis, thereby delaying proper treatment and prolonging disability. To prevent complications such as adhesions, perforation, obstruction of the common duct and chronic pancreatitis, it is necessary to recognize what Moynihan calls the "inaugural symptoms" of gall-stone disease, and to dismiss from our minds the typical text-book description of gall-stone colic.

Disease of the gall-bladder has its own type of digestive disturbance. According to Graham, we may distinguish four stages in its development and symptomatology.

In the first stage we see mild disturbance of the stomach, which occasions little distress to patients or anxiety to the physician. Irregular attacks of indigestion accompanied by gas formation and a feeling of epigastric constriction or tightness are observed. These discomforts are sudden in their onset and are frequently accompanied by chilliness, belching, regurgitation, or vomiting. Such dyspeptic attacks, sudden, irregular and mild, are as characteristic of early gall-bladder disease, as the typical attacks of gall-stone colic, which may ensue unless the trouble is recognized and proper treatment instituted.

In the second stage the disease occurs with pain, which may be dull or severe, and is located under the right costal arch. This pain may be aggravated by food, by sudden exertion or deep inspiration, and unless a careful physical examination of the chest is made, the physician may explain the symptoms by a diagnosis of pleurisy. These attacks of pain and dyspeptic disturbances are frequently evanescent in type, and with their going the patient enters on a period of good health.

In the third stage we have attacks of gall-stone colic, and here the diagnosis is easy. It is in this class of cases that the surgeon is most frequently called. These patients come with a well-defined history of sudden, excruciating pain located in the upper part of the abdomen, radiating to the right scapula and attended by nausea and vomiting. We have here, also, gas formation and spasm of the diaphragm; vomiting may give partial or complete relief, though morphin is most frequently required. A characteristic of these attacks is the suddenness of the onset and disappearance. The patient is unable to trace any connection between the beginning of the attack and the taking of food. Even in this advanced stage of the disease there may be a return of perfect health, which may continue for an indefinite period, to be suddenly interrupted in most cases by another severe attack.

The fourth stage represents chronic gall-bladder disease, with further complications of adhesions, obstruction of the common duct or pancreatitis. The diagnosis is not clear in this type unless the history of the case is carefully studied. Too frequently the significance of the symptoms or the urgency of the case is not appreciated until this stage is reached, and in view of former teaching, such a mistake is entirely reasonable.

Unless one has seen patients with gall-stone disease in the first or second stage operated on, it will be difficult for one to appreciate the constancy with which operation in these cases shows pathologic conditions of the gall-bladder. That operation relieves such patients and cures their "dyspepsia," is amply proved by the large number of patients operated on in most of the clinics in this country. These patients, who have definite symptoms of the first or the second stage, and are cured by operation, are the best proof of the association of gastric disturbances with the presence of gall-stones. Occasionally, we see cases in which the gall-bladder is packed with stones, thickened and adherent, and still there have been no symptoms other than the gastric disturbances already mentioned. The following case in the service of Dr. J. Shelton Horsley illustrates this point.

Case 1.—*History.*—Mrs. P., aged 37, a thin, emaciated woman, had suffered with stomach trouble and indefinite dyspepsia for the past twenty years. She complained of a "dull, aching, swollen feeling" in the upper abdomen, which sometimes radiated to the right shoulder and was frequently made worse by eating. She had had considerable bloating and belching. There had been no colic, jaundice, or pain severe enough to require a physician. Vomiting, which occurred only a few times, brought relief, though she usually obtained relief by drinking hot water. She said, "I have taken a lot of medicine for indigestion, which would relieve me for a while."

Diagnosis and Treatment.—Cholecystitis, with probably enlarged gall-bladder. Operation showed that the gall-bladder was enlarged, adherent to the anterior abdominal wall and surrounding tissues, and its walls thickened from chronic inflammation. It contained a thick purulent fluid, twenty-two large stones, with one stone completely occluding the cystic duct. We have here an illustration of the fact that even dvanced pathologic lesions of the gall-bladder may exist in a patient who complains of nothing but stomach trouble and slight pain. A letter recently received from this patient states that she is feeling better and weighs more than she has for sixteen years.

In making a diagnosis of gall-stone disease the etiologic possibilities should be gone into. It has long been noted that gall-stones often occur after typhoid fever, and are most frequent in women after pregnancy. It is probably also true that any systemic infection which produces toxins that irritate the mucosa of the gastro-intestinal tract may be a cause of cholecystitis, which, as we know, in its mild form is a forerunner of gall-stones. In the following case the patient's symptoms dated quite definitely from an attack of influenza.

Case 2.—*History.*—Mr. D., aged 45. The patient has had recurring pains in the epigastrium and lower abdomen for the past eighteen months; was well up until that time, when he contracted influenza. Since then he has had indigestion and pain in the stomach and lower abdomen. Pain and attacks of indigestion were irregular and alternated with periods of partial relief. There was no history of colic, cramps or jaundice, but his complexion he thought was slightly tinged at times.

Diagnosis and Treatment.—Operation showed cholecystitis and chronic appendicitis. The appendix was removed and the gall-bladder drained. This case gave a somewhat mixed type of stomach disturbance from both the appendix and the gall-bladder and may be an instance of cholecystitis from a general influenzal infection. The experiments of Else show that the gall-bladder is frequently infected through the general circulation and not through the portal system. If we accept his conclusion we can readily believe that a severe systemic infection without intestinal lesion could produce gall-bladder trouble. The operation revealed an appendix that was inflamed and moderately diseased and a gall-bladder somewhat thickened and congested and containing thick dark bile, but no stones. Removal of the appendix and drainage of the gall-bladder were followed by prompt recovery.

This patient was a farmer and had been in good health until the attack of influenza. So the relation of cause and effect between the influenza, the cholecystitis and the appendicitis may be assumed with apparent justification. It is probable that in such a case the gastric and intestinal mucosa are as much irritated as that of the gall-bladder and appendix, but the poor drainage of these two organs seems to render them unable to throw off the effect of the irritation as the stomach and intestines do.

Gall-bladder disease must be differentiated from ulcer, cancer, gastric neurosis, and reflex disturbance from chronic appendicitis. In ulcer of the stomach and duodenum there is a history of pain in the upper abdomen, coming on from one and one-half to four hours after meals, and relieved by food or by vomiting or by alkalies. The periodicity in ulcer is lacking in gall-stones. There is a definite relation between the taking of food and the relief of pain in ulcers, which contrasts with the sudden, irregular, and fleeting attacks of cholecystitis, which, in most cases, are not influenced in any way by eating. Formation of gas and the feeling of constriction, with belching, constitute a type of disturbance which accompanies gall-bladder trouble and which is not often found in ulcer.

Cancer of the stomach in about 70 per cent. of cases is said to result from ulcer, and its incipiency is diagnosed with great difficulty. A history of previous ulcer of the stomach should warn us of the approach of malignancy, and suggest a careful study of the case and gastric analysis. In cancer, the appearance of the patient, the irregular vomiting and the disgust for food, contrasted with the symptoms and well-preserved appearance of the patient suffering with ulcer or gall-stones, should be of some assistance in making a correct diagnosis. Blood is rarely found in gall-bladder cases. In ulcer it is present in one-fourth as against two-thirds of the cases of cancer of the stomach. Gastralgia is found in neurotic individuals, is relieved by pressure, and is not usually attended by nausea or vomiting. It is significant that a more thorough study of the pathology of lesions of the stomach and associated organs of digestion materially reduces the number of patients suffering with so-called gastralgia and other neuroses.

We might be called on to distinguish the girdle pain of locomotor ataxia from an attack of gall-stone colic. Here the Argyll-Robertson pupil, Romberg symptoms, loss of tendon reflex, and other signs of tabes would serve to differentiate.

Disturbance arising from the appendix, shown by gastric indigestion and pyloric spasm, are extremely difficult of diagnosis from primary gall-stone disease, and the two troubles frequently co-exist.

There may be no tenderness over McBurney's point or any other of the usual signs of appendicitis except a type of continuous stomach trouble. In these cases, however, the history may show an attack of appendicitis, which was not treated at the time of its occurrence, and the patient is able to date his indigestion from this attack. There is generally a loss of weight and considerable impairment of health. The effect of food on the pain is variable and the pain is usually in the neighborhood of the umbilicus. In appendical dyspepsia, its continuous type is in marked contrast to the fleeting, irregular and sudden attacks of gall-bladder trouble, and to gastric ulcer, in which there is generally a definite relation between pain and the taking of food. Cannon, of Boston, has succeeded in producing erosion and ulceration of the stomach by the injection or irritants in the cecum. These experiments would seem to indicate that even organic trouble of the stomach may be produced by disturbance in the region of the ileocecal valve.

The only satisfactory treatment of gall-stones is their surgical removal. Occasionally patients recover after passage of the stone by ulceration through into the bowel or into the stomach, or the patient may go through life a chronic dyspeptic and die of some other disease. It is as much the mission of physicians and surgeons to relieve morbidity as to lower mortality, and though the relation between these two things is not always directly apparent, it nevertheless exists in every case. A patient with indefinite stomach trouble, such as is found in the early stage of gall-stone disease, is more susceptible to other diseases, even if the gall-bladder trouble never assumes a threatening attitude in itself.

The medical profession is practically going through now, in regard to gall-bladder disease, what they have already learned in regard to appendicitis. The modern physician does not think of waiting in appendicitis until an abscess has formed, but recommends that the appendix be removed as soon as it is known to be diseased. So in the case of gall-stones, instead of waiting until the patient has had the early stages and has begun to suffer from colicky pains, vomiting and jaundice, the gall-stones should be diagnosticated in the first stage when the irregular attacks of gastric disturbance, with the feeling of constriction and the formation of gas in the stomach, show that as yet there has been practically no organic change in the liver, gall-tracts, or pancreas. Removal of the stones at such a stage will almost certainly insure a return of the patient to perfect health.

VACCINATION AND SMALL-POX IN JAPAN

S. KITASATO, M.D.
Director, Institute for Research in Infectious Diseases
TOKYO, JAPAN

Since Jenner introduced the practical use of vaccination over a century ago, mankind in general has been well protected from the cruel onslaught of small-pox wherever the process is carried out. We are greatly surprised every now and then to find antivaccinationists among people far advanced in civilization like those of the United States of America. I should, however, never have attempted to make any criticism on their presumption, had not one of them, namely, Dr. Hodge, of Niagara Falls, referred to the facts gathered from our Japanese statistics in his paper in the *Twentieth Century Magazine*. I may be permitted, therefore, to try to make clear how vaccination is serving to wipe out small-pox in Japan.

I. EPIDEMIOLOGIC OBSERVATIONS ON SMALL-POX AND ON PREVENTIVE MEASURES IN JAPAN

The free communication between Japan, China and Corea in earlier days was the source which gave rise to great epidemics of small-pox quite frequently, until at last vaccination was introduced. Japanese history tells us that small-pox was imported for the first time into Kyushyu in the month of February, 123 B. C., after which it gradually spread toward the east as far as Kyoto, causing a great epidemic all over the country, creating sad havoc, and strewing the high roads with the dead and dying. From this first great epidemic down to 1868, when the restoration of the present Meiji Era set in, about fifty epidemics broke out, each one of which extended over a number of years, sweeping all through the country, diminishing the population considerably and devastating the fertile country everywhere. Towards the end of the Tokugawa Shogunate the measure introduced by Jenner was adopted in Japan, with what favorable results we shall see below. During the ten years from the beginning of the Meiji Era—i. e., 1875-1884—the number of patients suffering from small-pox averaged 2,008.1 per hundred thousand population, while the deaths were only 494.6, which was deemed to be a remarkable improvement.

One of the greatest epidemics of small-pox during the past forty years broke out in 1885 and lasted three years, with 125,315 cases and 31,960 deaths. The epidemic began to decline in 1888. It reappeared in 1892 and again lasted three years. During this second outbreak 88,095 cases were recorded, of which 23,603 patients died. The third outbreak extended over two years, 1896-1897, with 52,650 cases and 15,664 deaths. During the next ten years, a few cases were imported from China every now and then, without any ensuing serious outbreak. Since 1900, the cases in the whole empire were remarkably few, until in 1907, when the disease reappeared at Kobe. This caused an uncommonly severe epidemic, which spread all through the empire. It began to die out in the spring of 1908. During this fourth epidemic 19,101 cases and 6,273 deaths were reported. This outbreak, however, completely subsided by July of the same year, without any trace left. The diagram inserted shows these epidemics most clearly.

Let us now turn our attention to what has been done to avoid the wretched results brought about by small-pox in Japan. In olden times when people were ignorant of what measures they should apply, they resorted to

In the second stage the disease occurs with pain, which may be dull or severe, and is located under the right costal arch. This pain may be aggravated by food, by sudden exertion or deep inspiration, and unless a careful physical examination of the chest is made, the physician may explain the symptoms by a diagnosis of pleurisy. These attacks of pain and dyspeptic disturbances are frequently evanescent in type, and with their going the patient enters on a period of good health.

In the third stage we have attacks of gall-stone colic, and here the diagnosis is easy. It is in this class of cases that the surgeon is most frequently called. These patients come with a well-defined history of sudden, excruciating pain located in the upper part of the abdomen, radiating to the right scapula and attended by nausea and vomiting. We have here, also, gas formation and spasm of the diaphragm; vomiting may give partial or complete relief, though morphin is most frequently required. A characteristic of these attacks is the suddenness of the onset and disappearance. The patient is unable to trace any connection between the beginning of the attack and the taking of food. Even in this advanced stage of the disease there may be a return of perfect health, which may continue for an indefinite period, to be suddenly interrupted in most cases by another severe attack.

The fourth stage represents chronic gall-bladder disease, with further complications of adhesions, obstruction of the common duct or pancreatitis. The diagnosis is not clear in this type unless the history of the case is carefully studied. Too frequently the significance of the symptoms or the urgency of the case is not appreciated until this stage is reached, and in view of former teaching, such a mistake is entirely reasonable.

Unless one has seen patients with gall-stone disease in the first or second stage operated on, it will be difficult for one to appreciate the constancy with which operation in these cases shows pathologic conditions of the gall-bladder. That operation relieves such patients and cures their "dyspepsia," is amply proved by the large number of patients operated on in most of the clinics in this country. These patients, who have definite symptoms of the first or the second stage, and are cured by operation, are the best proof of the association of gastric disturbances with the presence of gall-stones. Occasionally, we see cases in which the gall-bladder is packed with stones, thickened and adherent, and still there have been no symptoms other than the gastric disturbances already mentioned. The following case in the service of Dr. J. Shelton Horsley illustrates this point.

Case 1.—*History.*—Mrs. P., aged 37, a thin, emaciated woman, had suffered with stomach trouble and indefinite dyspepsia for the past twenty years. She complained of a "dull, aching, swollen feeling" in the upper abdomen, which sometimes radiated to the right shoulder and was frequently made worse by eating. She had had considerable bloating and belching. There had been no colic, jaundice, or pain severe enough to require a physician. Vomiting, which occurred only a few times, brought relief, though she usually obtained relief by drinking hot water. She said, "I have taken a lot of medicine for indigestion, which would relieve me for a while."

Diagnosis and Treatment.—Cholecystitis, with probably enlarged gall-bladder. Operation showed that the gall-bladder was enlarged, adherent to the anterior abdominal wall and surrounding tissues, and its walls thickened from chronic inflammation. It contained a thick purulent fluid, twenty-two large stones, with one stone completely occluding the cystic duct. We have here an illustration of the fact that even advanced pathologic lesions of the gall-bladder may exist in a patient who complains of nothing but stomach trouble and slight pain. A letter recently received from this patient states that she is feeling better and weighs more than she has for sixteen years.

In making a diagnosis of gall-stone disease the etiologic possibilities should be gone into. It has long been noted that gall-stones often occur after typhoid fever, and are most frequent in women after pregnancy. It is probably also true that any systemic infection which produces toxins that irritate the mucosa of the gastro-intestinal tract may be a cause of cholecystitis, which, as we know, in its mild form is a forerunner of gall-stones. In the following case the patient's symptoms dated quite definitely from an attack of influenza.

Case 2.—*History.*—Mr. D., aged 45. The patient has had recurring pains in the epigastrium and lower abdomen for the past eighteen months; was well up until that time, when he contracted influenza. Since then he has had indigestion and pain in the stomach and lower abdomen. Pain and attacks of indigestion were irregular and alternated with periods of partial relief. There was no history of colic, cramps or jaundice, but his complexion he thought was slightly tinged at times.

Diagnosis and Treatment.—Operation showed cholecystitis and chronic appendicitis. The appendix was removed and the gall-bladder drained. This case gave a somewhat mixed type of stomach disturbance from both the appendix and the gall-bladder and may be an instance of cholecystitis from a general influenzal infection. The experiments of Else show that the gall-bladder is frequently infected through the general circulation and not through the portal system. If we accept his conclusion we can readily believe that a severe systemic infection without intestinal lesion could produce gall-bladder trouble. The operation revealed an appendix that was inflamed and moderately diseased and a gall-bladder somewhat thickened and congested and containing thick dark bile, but no stones. Removal of the appendix and drainage of the gall-bladder were followed by prompt recovery.

This patient was a farmer and had been in good health until the attack of influenza. So the relation of cause and effect between the influenza, the cholecystitis and the appendicitis may be assumed with apparent justification. It is probable that in such a case the gastric and intestinal mucosa are as much irritated as that of the gall-bladder and appendix, but the poor drainage of these two organs seems to render them unable to throw off the effect of the irritation as the stomach and intestines do.

Gall-bladder disease must be differentiated from ulcer, cancer, gastric neurosis, and reflex disturbance from chronic appendicitis. In ulcer of the stomach and duodenum there is a history of pain in the upper abdomen, coming on from one and one-half to four hours after meals, and relieved by food or by vomiting or by alkalies. The periodicity in ulcer is lacking in gall-stones. There is a definite relation between the taking of food and th relief of pain in ulcers, which contrasts with the sudde irregular, and fleeting attacks of cholecystitis, which, most cases, are not influenced in any way by eati Formation of gas and the feeling of constriction, w belching, constitute a type of disturbance which ac panies gall-bladder trouble and which is not often f in ulcer.

Cancer of the stomach in about 70 per cent. of c said to result from ulcer, and its incipiency is dia with great difficulty. A history of previous ulcer stomach should warn us of the approach of mali and suggest a careful study of the case and analysis. In cancer, the appearance of the pat irregular vomiting and the disgust for food, c with the symptoms and well-preserved appear patient suffering with ulcer or gall-stones, sh

superstitious means to attempt to subdue the natural processes. One of the scientific measures, i. e., variolation, was introduced by a Chinese merchant, Lee-Nin-Shan, in the year 1745. That often caused an outbreak of small-pox, and so many fell victims to it that people felt that they were doomed to suffer from small-pox once during their lifetime.

In 1849, i. e., fifty-three years after Jenner had introduced vaccination, the process was first demonstrated in Japan by a Dutch physician, Monicke. The Japanese people were soon convinced of the marvelous effects of vaccination. Vaccinating stations were established in various great cities, e. g., Yeddo (now Tokyo), Kyoto and Osaka, in order to give the public the benefits of vaccination on a broader scale.

Japan, at that time, underwent a political change, and even medical science, which had begun to follow the teachings of the European school, was forbidden to continue by the Shogunate government. Vaccination was the only survivor of the newly introduced methods of the European school. This fact alone explains how far even the obstinate Japanese authorities were convinced of the efficacy of vaccination. The radical change of government just forty-four years ago, which is known to history as the Restoration of the Meiji Era, brought about a completely new mode of politics, everything Occidental being introduced. In 1874 the first vaccination law was enacted, and in 1876 the regulations for the prevention of small-pox were promulgated, which provided for compulsory vaccination. In 1885 a revised law concerning vaccination was enacted. It comprised all the data included in the former two regulations. It provided that every baby should be vaccinated within the first year of its age, and revaccinated every five or seven years. The violation of this regulation was punished with a fine not less than 5 and not exceeding 50 sen (or approximately, from 2½ to 25 cents in U. S. currency). It was in the same year, just after the enactment of these regulations, that the great epidemic broke out which is mentioned above. This regulation remained unchanged during twenty-four years; a new revision took effect in the year 1909. This new law provides that each new-born baby shall be vaccinated within ninety days after birth and before June of the next year. Revaccination shall be made at the tenth year from birth (including the year in which the child was born). If either the primary or the secondary vaccination is unsuccessful, the child shall be revaccinated before December of the next year.

Formerly Japan, as well as every other country, used humanized lymph only. The retrovaccine was then used from 1892 till 1900. In 1900 the present "pure animal lymph" was substituted. While humanized [illegible]able and used, the original vaccine was supplied from th[illegible] vaccinating stations. In 1874 the Japanese government established a calf-lymph farm, in order to meet the demands of the general public. In 1888 the preparation of calf-lymph was entrusted to the Japan Health Association, which continued to prepare the lymph for eight years. During these years, other private institutions made their appearance which prepared calf-lymph for pecuniary considerations. The products of these private enterprises were unsatisfactory, for the efficacy of such lymph eventually became questionable and at last public opinion was aroused to establish a national institution for the preparation of calf-lymph, and in 1896 such an institution was established. In this institution Dr. Umeno tried the experiment of preparing a "pure animal lymph" by passing the virus only through the calf, never using a human body as had been done previously. He succeeded in this experiment, and since 1900 this kind of calf-lymph has been supplied to the public. The original calf-lymph farm was closed in the year 1906, and the calf-lymph is now prepared in the Institute for Research on Infectious Diseases.

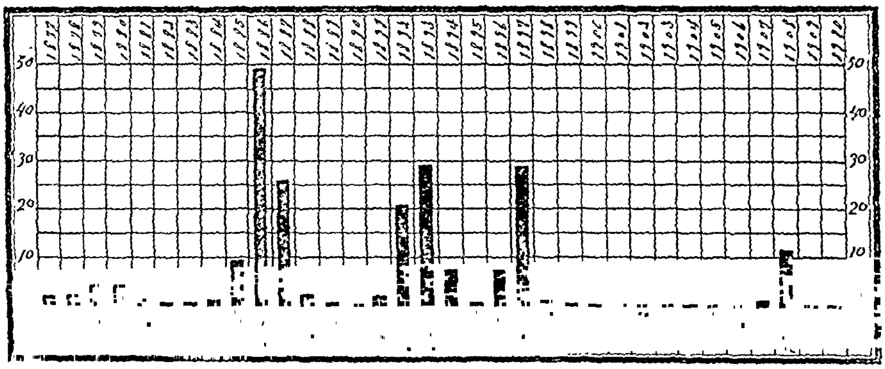

Diagram of small-pox mortality in Japan.

II. THE CAUSES OF THE EPIDEMICS OF SMALL-POX IN JAPAN

Ever since the promulgation of the first vaccination law in 1874, and that of the second one in 1876, when compulsory measures were first adopted, Japan has suffered from epidemics from time to time. The inefficacy of vaccination might therefore seem to be proved to shallow-minded observers, who do not fully realize the complicated nature of the origin of small-pox as well as of other infectious diseases. These various causes should be thoroughly examined before the *reliability* of vaccination is questioned. Let us now, therefore, review the epidemiology of small-pox in Japan.

There seem to be at least five principal causes to account for the presence and continuance of small-pox:

1. The Importation of the Virus.—Japan is surrounded by seas, beyond which lie several countries where preventive measures have never been taken. In these countries, small-pox exists continuously and at every possible opportunity invades Japan. When we had only a limited means of communication some centuries ago, each epidemic could be traced back to importation of the virus from China through Corea, and in course of time the more the facilities of communication were augmented the more the country was found to be liable to infection. This compelled us to establish quarantine stations, which were opened in 1899. Since that date, and until the end of 1909, the number of detected cases of small-pox at these stations amounted to seventy-one, as is shown in Table 1:

TABLE 1.—NUMBER OF CASES OF SMALL-POX DETECTED AT QUARANTINE STATIONS DURING THE YEARS FROM 1899 TO 1909

Quarantine Station	1899	1900	1901	1902	1903	1904	1905	1906	1907	1908	1909	
Yokohama	1	3	.	.	1	.	1	2	3	5	.	—16
Kobe	1	1	1	.	1	3	7	2	1	7	2	—26
Moji	.	1	.	.	.	5	4	.	1	6	2	—19
Nagasaki	1	.	2	1	.	1	.	1	3	1	.	—10
Total.......	3	5	3	1	2	9	12	5	8	19	4	—71

some ass[illegible]gures, of course, exclude by necessity those rar[illegible]ssed the stations in the stage of incubation, which obviously made the prevention of the disease most difficult. The same difficulty is encountered in the most completely vaccinated country — Germany — which is bounded on one side by Russia, a non-vaccinated country. This is why there exist a few unavoidable cases of small-pox annually in that country. Imagine, then, how great is the chance of infection in Japan, which is in close proximity to China and Corea, whose condition of national health hardly admits even any comparison with that of Russia. This is one of the most conspicuous causative factors in the reappearance of small-pox in Japan. Japan is therefore never tired of preaching the gospel of vaccination, not only within her own dominions, but also as far as her sphere of influence permits.

2. *Non-Vaccinated People.*—Laws cannot be expected to be all-powerful. Wherever there is a law, there are also to be met not a few law-breakers, even when the breach is met with severe penalties. It admits of no doubt that such laws as regulate matters of public health provide but slight penalties, and consequently there are not a few law-breakers among the ignorant mass of people. This fact will appear when we come to examine the figures given in our statistics, which equal nearly the whole population of the country. But the more minute particulars, which are not shown in the statistics, will clearly show the vague notion we have of the number of non-vaccinated individuals there are scattered throughout the country. Among the 10,600 persons with small-pox reported during the five years including 1878-1882, non-vaccinated individuals were found to amount to 63 per cent., or 6,690. Then again, during the latest epidemic, in the years 1907-1908, 1,527 non-vaccinated persons among 5,215 small-pox patients were found in one prefecture, i. e., in Hiogo.

Such law-breakers probably will be found in any nation where a vaccination law is enacted. The middle and higher classes of Japanese people never allow their children to go unvaccinated, but the lower classes, who constitute the majority of the nation, often neglect their duty. They are, like kerosene oil in a house where a fire breaks out, fuel for the flames, furnishing every possible chance for the spread of the disease. Under the revised vaccination law taking effect in the year 1909, the hitherto irresponsible protectors of children were subjected to penalties for failure to have them vaccinated.

3. *Unsuccessful Vaccination.*—The protection of the individual against small-pox is never complete unless the points of inoculation develop the typical pustules, and the patient undergoes a regular symptomatic change. In order to bring about complete immunization in a human body, the quality of the vaccine lymph and the technic of vaccination must be considered.

In Japan, from the first year of the enactment of the vaccination law in 1887 up to 1907, covering twenty-two years, the reported number of vaccinations was 97,355,-246, of which 73,259,278 were compulsory and the remaining 24,355,968 voluntary. The average number of vaccinations per year was more than 4,420,000. Comparing this number with the whole Japanese population, there seems to be no one who has not been vaccinated: but a close examination of the real state of affairs will make clear the fact that in the above-mentioned large number of vaccinations are a certain number of unsuccessful vaccinations. Of course this large number of unsuccessfully vaccinated persons may also comprise some who have already acquired immunity by previous vaccination. At the same time we must not overlook those who have been unsuccessfully vaccinated because of unskilful manipulation on the part of the physicians, who had practiced the puncturing system instead of the cutting method, even when the lymph had been changed for the retrovaccine and this again for the "pure animal lymph." The effect of this may be seen from the statistics, which show a great difference between the percentage of the primary vaccinations gathered from the eight years before 1891 and after 1892. In the first eight years when the humanized lymph had been used the percentage of successful vaccinations was high, ranging from 85 to 90 per cent., but in the later eight years when the retrovaccine was introduced the percentage fell suddenly to 75 or 80. The figure, however, has been greatly increasing since 1900, when it reached as high as 88 per cent.

In short, it must be acknowledged that vaccination in Japan is so irregular that while there are some who receive no vaccination until five or six years of age, others have been vaccinated three or more times during the same period of time, and the consequence is the comparatively less number of genuine vaccinations. This evil will be overcome by the adoption of the latest radical policy.

4. *The Immunity Acquired Through Vaccination.*—Immunity through vaccination is not complete before three weeks after successful vaccination. This is why there are some cases of small-pox immediately following vaccination. Then again, the immunity is gradually weakened by the course of years. This fact may be seen from the following statistics:

Successful revaccination after—

1 year	13.6 per cent.	4 years	57.3 per cent.
2 years	32.9 per cent.	5 years	51.1 per cent.
3 years	46.6 per cent.	6 years	63.8 per cent.

This shows the percentage among the 951 cases observed in Japan.

7 years	72.5 per cent.	9 years	85.0 per cent.
8 years	80.0 per cent.	10 years	88.6 per cent.

These results were obtained by Weil in the year 1899.

The government report of the German Confederacy shows 91 to 93 per cent. of successful revaccinations after ten years from the primary. In other words, the immunity acquired through vaccination begins to disappear from the second year and by the tenth year it disappears almost completely. And therefore in Germany, and in some other countries, a law has been enacted to have the people revaccinated at the eleventh year from the primary vaccination.

The general statistics do not give these minute facts in detail, and therefore the deduction is imperfect. Had not the critics excluded these cases from the total revaccinated ones, they could not come to the conclusion which Dr. Hodge reached. For instance, during the latest epidemic in Japan, which broke out in 1907-1908, 608 patients were admitted into the Higashiyama Hospital in Kobe: 267 of the number were non-vaccinated, the past history of thirty-eight was uncertain as to the vaccination, twenty-five had contracted the disease within three weeks after vaccination, four had had small-pox previously, nineteen contracted the disease within five years and 225 over five years from the last vaccination. This shows also how far the immunity is impaired by the lapse of time.

5. *Virulency of Small-Pox.*—The virulency of small-pox is not constant in each epidemic. The higher the virulency of small-pox rises, the larger the number of cases among those who have passed several years from the last vaccination. Then, it may be asked, how can the virulency of small-pox be estimated? The simplest

way, it seems to me, is to estimate the death-rate among the non-vaccinated patients. The average death-rate of small-pox is estimated at from 20 to 40 per cent. in the European literature. In Japan, it shows a higher standard, ranging from 25 to 30 per cent. even during the small epidemics. During the epidemic of 1896-1897 it averaged 55.08 per cent., and that of the years 1907-1908 reached the high standard of 69.4 per cent. When the virulency reaches this high point, higher than has been encountered in European or American epidemics, even individuals previously attacked, as well as those vaccinated, contract the disease. During the latest epidemic, such cases were numbered at 242 in seven prefectures, viz., Hiogo, Osaka, Tokyo, Kanagawa, Hiroshima, Aichi and Wakayama, and fifty-seven died. The death-rate, therefore, was 23.5 per cent. This is unmistakable evidence of the strong virulency of the small-pox which prevailed at that time. It is like a devastating fire which consumes everything in its path and to which nothing is fire-proof. Japan dreads this kind of small-pox, which is also abetted by the other circumstances, but its direct results are by no means due to the inefficacy of vaccination.

III. THE EFFICACY OF VACCINATION

The efficacy of vaccination can be demonstrated by experiment, experience and statistics.

1. The fact that vaccinated individuals do not contract small-pox was made clear by Woodylle, William and others immediately after Jenner's experiment, by inoculating the virus of small-pox into the vaccinated individual. In modern times the same experiment has been made, of course for different purposes, with monkeys. Brinkerhoff and Magrath before the year 1904, and Dr. Miyajima, one of my assistants, in 1908 vaccinated a large number of monkeys with calf-lymph, and then inoculated them with the virus of small-pox, but none of the experimental animals contracted the disease. This is an established fact in science, and there is none who can deny it.

2. Empirical testimony can be best drawn from the great epidemics, in which a great many persons engage in transporting, nursing, inspecting and disposing of both the sick and the dead without the least apprehension, because every one of them has received a thorough vaccination. In Japan, those who engage in this kind of work are vaccinated regularly within a certain period of time, and the consequence has been that none of them fell a victim to the pestilence. If, on the contrary, they had never been vaccinated, the result would be nothing but disastrous. If vaccination had no preventive effect on small-pox, they would have fallen victims before anybody else. If, then, the results had occurred just the reverse to the real state of things as claimed by the Jennerists, they should have abandoned their claims a long time ago. But the general public outside the profession is well convinced of the efficacy of vaccination simply because of this empirical testimony, which constitutes an indisputable fact.

3. Statistical facts also bear witness to the efficacy of vaccination. But tables and diagrams shown in statistics do not explain themselves. The most minute and scrupulous examination as to the hidden meaning of them, which only can breathe into the dry framework of figures the spirit of truth, is necessary, so that fallacy may be avoided. In almost every civilized country where there is a perfect system of vaccination in vogue, there occur no great epidemics of small-pox, and consequently the death-rate among th [illegible] an epidemic should occur, it would soon yield to va cination.

Unfortunately, in Japan we are still having occasional epidemics of small-pox, which constitute for certain fanatic superficial observers a sad example of the inefficacy of vaccination. We have ample reason to believe, however, that the very things which Dr. Hodge and other antivaccinationists hold as evidence against Jennerism are the solid rocks on which the statistical proof of the efficacy of vaccination rests.

In the first place, in proportion as the system of vaccination had been perfected, the period of each epidemic and the number of deaths are diminished. This fact may be seen from Table 2:

TABLE 2.—NUMBER OF CASES, DEATHS AND DEATH-RATE PER HUNDRED IN VARIOUS EPIDEMICS

FIRST EPIDEMIC

	Cases	Deaths	per 100 Death-Rate
1885	12,759	3,329	26.09
1886	73,337	18,676	25.47
1887	39,779	9,967	25.06
Total	125,315	31,962	

SECOND EPIDEMIC

	Cases	Deaths,	Death-Rate per 100
1892	33,779	8,409	24.89
1893	41,898	11,852	28.29
1894	12,418	3,342	26.91
Total	88,095	23,603	

THIRD EPIDEMIC

	Cases	Deaths	Death-Rate per 100
1896	10,704	3,388	31.65
1897	41,946	12,276	29.27
Total	52,650	15,664	

FOURTH EPIDEMIC

	Cases	Deaths	Death-Rate per 100
1907	1,034	437	42.25
1908	18,067	5,836	32.32
Total	19,101	6,273	

The first and the second epidemics each lasted fully three years, and the third two years, while the fourth broke out in December, 1907, and ceased completely in August of the following year, covering a period of less than a year. The number of cases again shows a gradual decrease. While the first epidemic had over 100,000 cases, the second had 80,000 and the third 50,000, the fourth had less than 20,000.

The marvelous effect of vaccination on the epidemics of small-pox is manifested in Table 3, which shows the sudden fall in new cases during the epidemic, which otherwise would have increased. The table does not show the long list of the vaccinated persons, but from the beginning of the epidemic down to the close a special vaccination was enforced on all persons who were brought under the control of the hygienic police power.

TABLE 3.—MONTHLY REPORT OF SMALLPOX DURING THE YEARS 1907 AND 1908

	Cases	Deaths
August, 1907	4	2
September, 1907	1	0
October, 1907	25	6
November, 1907	90	31
December, 1907	770	383
January, 1908	4,481	1,394
February, 1908	5,424	1,498
March, 1908	4,685	1,461
April, 1908	1,815	895
May, 1908	926	314
June, 1908	526	185
July, 1908	121	73
August, 1908	36	28

During this epidemic a striking effect of vaccination in mitigating the virulency of small-pox was experienced.

While it prevailed in Hiogo and Osaka, special compulsory vaccination was enforced, and consequently in Kanagawa, Tokyo, Aichi and Kyoto it prevailed less furiously, as is shown in Table 4:

TABLE 4.—RESULTS OF COMPULSORY VACCINATION

Place and Date First Case Appeared	Cases	Deaths	Death-Rate, Per Cent.
Hiogo, August, 1907	5,215	2,315	44.4
Osaka, November, 1907	3,431	1,641	47.9
Kanagawa, December, 1907	684	209	30.5
Tokyo, January, 1908	1,479	379	26.8
Aichi, January, 1908	800	169	21.1
Kyoto, December, 1907	263	38	14.4

The drop in the figures in cases and deaths could never have been so great had it not been for the effect of vaccination.

6. The death-rate in small-pox is given as about 30 per cent. by authorities, but it shows a wide range of figures in various epidemics, just as we see in any other infectious disease. Again, the comparison between the death-rate of small-pox among vaccinated persons and non-vaccinated ones cannot be established unless the data be collected from only one locality in the course of one epidemic. In Japan we have rare statistics which show such comparison. They cover five years from 1878 to 1882. The total number of cases during that time amounted to 10,600, of which number the following figures are given:

	Cases	Deaths	Death-Rate per 100
Non-vaccinated	6,690	2,190	32.73
Vaccinated	3,910	455	11.63

From the above figures it will be seen that the mortality among the vaccinated persons was not more than one-third of that among the non-vaccinated.

The following figures show the same conditions, where clear distinction could be made between the vaccinated and non-vaccinated, in Tokyo, Kyoto, Osaka, Hiogo, Kanagawa and Aichi, where during the latest epidemic the cases numbered 10,286:

	Cases	Deaths	Death-Rate per 100
Non-vaccinated	2,932	2,031	69.3
Vaccinated	7,254	1,926	26.6

The above figures show the decrease in the death-rate among the vaccinated persons to one-half that of the non-vaccinated ones.

The vaccinated persons in the above table include those who were vaccinated within three weeks from the time of exposure and those who had passed the time assigned as the infective period. If these cases be deducted from the number the result would be more accurate.

During the epidemic of 1907-1908, the first case appeared in Kobe City and the disease prevailed most severely there. The Higashiyama Hospital at Kobe admitted 608 patients in all, who may be classified as in Table 5:

TABLE 5.—CASES IN HIGASHIYAMA HOSPITAL

Class	Cases	Deaths	Death-Rate per 100
Non-vaccinated persons	267	134	50.19
Uncertain	38	6	15.79
Vaccinated	274	19	6.90
Within five years	19	0	0
Over five years	255	19	7.84
Vaccinated during incubation period	25	3	12.00
Having previous attack	4	0	0
Total	608	159	26.15

From this table it will be clear that the death-rate among the non-vaccinated persons was 50 per cent., while that of the vaccinated was 6.44 per cent., i. e., one-seventh that among the non-vaccinated. Again, all the deaths among the vaccinated persons occurred exclusively among those who had passed over five years from the last vaccination and among those who had been vaccinated during the incubation period. No one will doubt the efficacy of our Japanese vaccination, now that such a clear table of statistics is produced. Besides, the table shows that even among those who were vaccinated during the incubation period, the death-rate was four times smaller than that of the non-vaccinated ones.

7. There is, besides the above statistics, the following circumstance which constitutes still another strong piece of evidence. I refer to the statistics of our army during the two great wars, the Chino-Japanese and the Russo-Japanese. Our army engaged in both wars in Corea and Manchuria, where small-pox is endemic, and therefore the soldiers were constantly exposed to the danger of contamination; the more so when the unhealthy way of living which is a necessary concomitant of war is taken into account. However, the Japanese authorities took care to have every soldier who went to the seat of war vaccinated, and the happy result was that in an army consisting of not less than a million of men, the following small number of cases of small-pox appeared:

Chino-Jap. war: 155 cases; 34 deaths; death-rate, 21.93 per cent.
Russo-Jap. war: 362 cases; 35 deaths; death-rate, 9.66 per cent.

As the total number of men engaged in both wars is not yet made known, the rate of contamination and the death-rate cannot be accurately stated; however, we get from these approximate figures some notion as to the paucity of cases. The results are equal to, if not better than, those of the Prussian army during the war of 1870.

CONCLUSION

Japan is surrounded by non-vaccinated countries, whence contagion may flow in at any time, while the ignorant people do not care to receive vaccination; those who neglect it are therefore predisposed to be infected at the slightest chance. The enormous number of vaccinated individuals which appears in our statistics does not include all the people who should be vaccinated, but it does include a large number of persons revaccinated at an earlier time than the law of immunity requires, because they are well aware of the efficacy of vaccination as well as very anxious to protect themselves from the dangerous contagion.

From these various causes, there still prevail epidemics of small-pox in Japan. I regret that these statistics presented by our Japanese government have seemed to afford data for upholding the theory of the antivaccinationists in America. Every civilized individual of Japan knows the benefit of the marvelous discovery of Jenner, because he sees from time to time how he himself and his neighbors are protected from horrible epidemics. It seems to me that the presence of such an antivaccinationist as Dr. Hodge, who denies the efficacy of vaccination so frankly in the United States of America, is a striking witness to the fact that the people of America are already well protected by not having had the sad experience of an attack of small-pox for a long time, and by the fact that their neighbors are being thoroughly vaccinated. The antivaccinationists are like those who would deny the benefit of sunshine. It gives them every kind of joy and happiness, and yet they are so familiar with it that they are not aware of its good. They would come to know the vast protective power of vaccination, had they once experienced the terrible outbreaks of small-pox in their communities, in which thousands on thousands fall victims while the vaccinated ones go freely through the epidemic without the least danger of contagion.

STANDARDS AND AUTHORITY *

GEORGE EDGAR VINCENT

Dean of the Faculties of Arts, Literature and Science, University of Chicago; President-Elect, University of Minnesota

CHICAGO

"Monarchy," said Fisher Ames, "is like a merchantman; it sails well, but sometimes strikes a rock and goes to the bottom; democracy is like a raft; it never sinks, but your feet are always in the water." Thus with homely piquancy the Revolutionary sage set forth the conflict between the efficient élite and the unspecialized many. These contrasted views persist. In every institution, community, nation, these problems will not down: How shall the knowledge, experience, skill of the few be put at the service of all? If need be, how shall this wisdom be made coercive? How shall richer resources of science and technic be discovered and applied? With the change from country-side to city, from household to factory industry, from infrequent journeys to shuttle-like travel, from local to world markets, the problems of industry, commerce, health and politics become complicated and insistent. The horse-sense of a few decades ago will no longer serve an age of motor cars. The expert few are coming into their own. They assert superior knowledge and skill; they ask that these be recognized; they demand protection against sciolist, incompetent and quack. They seek to establish tests of individual training and efficiency for the few and to prescribe forms of conduct for the many. Thus fundamental questions are raised—questions of standards and of authority.

Plato in the "Republic" recognized these problems and provided for their solution. His "Republic" was an aristocracy of experts, an oligarchy of scientists. These guardians were highly trained, devoted to the common welfare. They could not transmit authority or privilege; they recruited their ranks from every social stratum in which they found ability. They were clothed with unquestioned power. They redistributed wealth, transferred children to the classes to which their aptitudes assigned them, censored literature and the drama—in short they made all decisions and imposed these on the mass of citizens. Plato assumed that truth could be discovered, that men could be trained to apply it and enforce it for the common good. Accurate science, a competent élite, and coercive power are to-day, as in Plato's time, conditions of adjustment to the life conditions of any social group, be it corporation, institution, community, state or nation.

Auguste Comte believed that authority ought to come from agreement; not agreement from authority. He had faith that with popular scientific education, "intellectual anarchy" would gradually disappear. Men would cease to explain phenomena by theological notions and metaphysical superstitions. They would, by the very constitution of their minds, be forced to agree, first, about mathematical relationships, then about celestial mechanics, next about physics and chemistry, finally about biology and social science. With the few something like this has come to pass. About most questions of the exact sciences educated men cannot differ. Discussion tends to take refuge in the fields of biology, psychology, philosophy and the social sciences. Even here science is steadily making conquests and robbing the intelligent of subjects for debate. But in another sense Comte's dream seems almost pathetic in its futility. The idea of the many accepting scientific knowledge from an appreciation of its validity and conforming their conduct to its demands, is still rather utopian. There are many who take a cynical view of popular education. They see medieval ignorance invading the twentieth century. Charlatanism, quackery and superstition run riot. Vagaries and absurdities sweep through a credulous public. Even they who have hope of making headway with scientific truth are not overconfident. "Against such education" writes one of these, "are naturally trained all the resources of quackery whose trade would be gone. And when free expression is accorded all alike, progress must be made in the teeth of ignorance too dense to have any conception of its own depth, and in the face of brawling charlatanry and screaming fanaticism."[1] In a sense, scientific knowledge and technic must always be a monopoly of the trained, efficient few. At any rate the participation of the many in this knowledge must be of a very different kind. To speak of modern science as a common possession of a whole population is misleading. The growth of science means specialization, and that means an élite. The degree to which the many appreciate the methods and spirit of science and recognize expert authority is a measure of popular intelligence.

There are professions and occupations that must be thought of as forms of social service rather than as personal careers. Thus doctors are rightly regarded as social servants. Their skill and fidelity are obviously vital to the community. Yet this view is far from universal. Individuals by tens of thousands see in a medical career chiefly a means of livelihood. They resent the rising standards of medical education as obstacles to the early enjoyment of an income. Many of these individualists resort to short-cut schools and to least resistance states. But these outcasts are embittered by exclusion from prestige and practice; they swell the ranks of the quacks and unfurl the black flag of the medical privateer. The discredited schools and "diploma-mills" also insist on the old dogmas of liberty and *laissez faire,* and make appeals to the traditions of the fathers, the spirit of '76 and other quaintly irrelevant ideas and shibboleths. Then, too, curious cults, recrudescent superstitions, attractive half-truths, esoteric mysteries are constantly arising to demand in the name of religion, free thought, or psychology, recognition as therapeutic agencies. To the influences which resist the standardizing of medical education may be added makers of proprietary remedies whose success varies directly with the credulity of the public. But in spite of impatient selfishness, mental inertia, sincere fanaticism, unscrupulous greed, the standardizing of medical education goes steadily, if too slowly, on. The Association under whose auspices we meet affords an example of that extra-legal centralized organization which creates national institutions amid what often seems a chaos of state particularism. Slowly but inevitably we are selecting a medical élite, experts to whom we entrust a constantly growing body of scientific knowledge and an elaborated technic.

It is essential that such an élite should be recruited from the widest area of possible ability. Society must provide a "drag-net" for special capacity. There is danger that the raising of standards may limit the field of choice to those groups which can afford the cost of long and expensive preparation. Socially and professionally such a result would be deplorable. If the community for its own protection insists on testing and training its social functionaries, it must provide a way of finding and encouraging unusual ability however this may be circumstanced. A system of scholarships, awarded by competent authority, after adequate tests, and continued only so long as the scholars' work justifies the support, would seem to be a socially necessary consequence of the increased demands of medical education. Medical associations, individuals, institutions and the states should all have a share in creating such a system.

---

* Read before the Conference of the American Medical Association on Medical Education and Medical Legislation, Chicago, March 1-3, 1911.

[1] Hodges: Pop. Sc. Monthly, xlix, 6167.

So far medical men have been spoken of as one body. It is worth while to mention here the subdivision of the group into the teachers of medicine, practitioners and sanitarians. These sub-groups overlap somewhat, but on the whole they differentiate themselves rather clearly. Medical teachers may be further divided into those who investigate and those who give instruction. It is of prime importance that all these groups should work in closest harmony and loyalty. Their task is in a large sense common to all. Each group for its own highest efficiency must keep itself informed of the work the others are doing.

Granted that a body of medical experts is in existence, that the recruiting of this body is being more carefully supervised, that it is being gradually protected against the worst forms of competition, and granted, further, that this élite is able to formulate policies to protect individual and public health, how bring about the acceptance of these policies by the community? An enlightened despotism could impose such regulations on humble and submissive subjects. Model industrial villages have at times afforded modern instances of sanitation by ukase. One can imagine Peter the Great bringing things to pass quickly in Petersburg when once he had been convinced of the germ theory of disease. Experts have a kindly feeling for despotism. They know what ought to be done and they are impatient of delay. They often display a trace of autocracy when they have a situation in hand. A bureaucratic system under which the masses transfer to a body of government officials much of the deference once shown to the nobility, may display, as in Germany, or even in Switzerland, a high degree of efficiency. Under a régime which places the center of the franchise high up in the social scale, gives a thorough system of elementary and technical education, passes its male population through a rigorous military machine, exalts technical skill and scientific knowledge, there is a remarkable yielding to expert guidance. No wonder that the medical élite turn their eyes enviously toward Berlin where the details of conduct are rigorously enforced. But there is a vast difference between the down-trodden victims of a scientific paternalism and the untrammelled citizens of triumphant democracy. A German must keep the soles of both feet on the floor of a tram car, but the free-born American may extend his boot to be polished by every passing skirt, and in the State of Alabama is protected by at least one court in asserting his inalienable right to copious and casual expectoration.[2] Obviously the central problem in democracy is to give prestige and authority to the élite and to their prescriptions.

While rising democracies like those of France and England preserve traces of traditional deference to the upper classes, the American people show no such attitude. On the contrary, they usually display hostility, or at least derisive disrespect, for the specialized and their opinions. To the unspecialized average man the expert is in a way a personal affront. He suggests the idea of a superior class, and seems to reflect on the competence of the ordinary citizen. This feeling is a natural survival from the early days, especially on the frontier. The problems of that simple life demanded not highly trained specialists, but men who could turn their hands to many different kinds of work, none of which was searchingly tested by competition or other spur to efficiency. Slowly, grudgingly the technical expert, the railway and mining engineer, the architect, of late the agricultural specialist, have been given recognition by the many. But against doctors, especially experts in insanity, sanitarians, university professors, and others who arrogate to themselves special knowledge that is not easily tested in tangible, material ways, the American democracy still directs a large measure of incredulity and derision. And this, too, in spite of constant resort to physicians and personal confidence in them in individual cases. It is the difference between "my doctor" and "the doctors." Then, too, for obvious reasons the antagonism is much more marked toward bacteriologists and sanitarians than toward physicians in private practice.

There are other causes of popular distrust of the specialized few. The public attributes to them motives of cupidity and of class interest. Such a phrase as the "Doctors' Trust" by its sinister suggestions is a clever device for appealing to this latent suspicion. Again, the traditional idea that it is derogatory to personal dignity to defer to superiors, the hypnotizing influence of cherished "inalienable rights," the tendency to identify opinionated obstinacy with personal liberty—all these curious confusions of ideas play some part in making the many hostile to the few. Universal schooling and access to newspapers, periodicals and books of popular science create in tens of thousands a sense of familiarity with the latest thought. They pick up phrases, they are the victims of verbal suggestion, they have the pride of opinion. They set their neighbors right about current questions and warn them against the selfish recommendations of the experts. One of these local oracles in stopping his subscription recently wrote the following lines to the *Outlook*:[3]

> I have carefully studied the vaccination question for several years, and am thoroughly conversant with the expressed views of many of the most prominent advocates and opponents of the practice in the world, and I assert, knowing absolutely that I cannot be intelligently and successfully contradicted, that there is now nowhere to be found a man of proven competency and well-established reputation for truth and probity, either in or out of the medical profession, who advocates vaccination.

The doctors are not blameless for a good deal of the popular prejudice. By a sometimes tactless assertion of superior knowledge they commit the unforgivable American sin of "setting themselves up to know more than other people." When a prominent medical man in testifying before a senatorial committee says: "My position is that of an expert whose testimony cannot be impeached," he is doubtless *stating a fact*, but to the average man the cool assertion is irritating. It arouses antagonism. Another cause of popular distrust of expert opinion and professional probity is the widespread belief that physicians and professors of medicine can be induced to give testimony on either side of a legal case. The public cannot enter into all the intricacies which make possible honest disagreement between well-trained men. The easy inferences are that medicine is mere guess-work, or that doctors are hypocritical and venial. If the proposal to make medical experts an impartial special jury, summoned and paid by the court itself, can be carried out, there will be a gain for the prestige of the profession. It is to be hoped, too, that the conviction of the poor that they are regarded as mere clinical material for human vivisection may be gradually removed. This persistent misconception plays some part in the prejudice against medical men. Obviously the profession suffers seriously, not only from the quacks and charlatans without the pale, but from the self-seeking and disloyal who violate the spirit while they cleverly keep within the technical rules of the medical fraternity. By playing on the ignorance of patients, by prolonging the period of treatment, by prescribing futile remedies and advising unnecessary operations, by extortionate charges, these men do untold damage to the profession and furnish just grounds for popular distrust and resentment. The medical élite must have the vigilance and courage to protect itself, not only against enemies without, but against traitors within. Again, it is possible, with some show of truth, to charge the doctors with being slow to recognize new knowledge and better methods. There are extremists who insist that the profession has always opposed progress. The injustice of so sweeping an assertion does not prevent its having a certain effect on public opinion. The industrious incompetence of large numbers of practitioners who, graduated from preposterous schools and admitted to practice by ridiculous boards of examiners, run their devastating careers in some of our states, does not deceive all who know them. Even if the public is undiscriminating enough to put all doctors into one class, it is not wholly to be blamed for regarding the entire group with a good deal of suspicion and derision.

[2] The Journal A. M. A., 1900, xxxv, 433.

[3] Outlook, Feb. 11, 1911.

Thus the more or less expert few face the many who trust individuals, but are slow to recognize the authority of the profession. What are the possibilities of reaching a better understanding? The answers are obvious: The few must deserve and win popular confidence; the many must learn to appreciate the competence and devotion of the few. And the state must formulate and enforce the terms of this better understanding. If the cure for democracy is more democracy, the corrective of a little education is more education. The only alternative is a return to autocracy. To the millenium-chaser, the short-cut reformer and the efficient administrator, the slow process of education is an irritating suggestion. They object to having their "feet always in the water."

But scientific men should face facts as they are. The public mind is like a force of nature. It is childish to rail at it, to denounce it, to expect it to be docile about technical matters. Doctors should diagnose the public calmly and in the scientific spirit. They should try to trace the play of cause and effect, and then take measures to bring desired results to pass. In this they have the right to ask the cooperation of all thinking men and women. The public is controlled by leaders. These leaders must be informed and intelligent. Colleges and universities have a responsibility to train these leaders. Every institution of higher education should be a model of public sanitation and hygiene. Every graduate should be well grounded in the principles of personal and community health. The public schools could do much more than they are doing at present to train children in hygienic habits and in intelligent deference to sanitary regulations. Popular literature, lectures, parents' meetings, visiting nurses' associations, organizations like the antituberculosis societies, city and state health departments and boards—agencies of many kinds are all engaged in the work of popular health education. Would that Mr. Carnegie's next ten million dollar gift might be devoted to publishing in newspapers authoritative advertising bulletins on hygiene and sanitation! Many an editor would be glad to be freed from irksome slavery to the patent medicine men.

A large responsibility for the education of the public must fall on members of the medical profession. Doctors and professors of medicine must devote some time to public addresses, to cooperation with public school authorities, to participation in local movements for improved sanitation, to hearty support of local health authorities when these are reasonably competent, and to civic movements designed to improve a defective public health service.

There is much platitudinous talk about legislation and public opinion. On the one hand are the doctrinaires whose one idea of social progress is to get some law passed. At the other extreme are to be found those who are so convinced that law unsupported by public opinion is futile, that they are in danger of neglecting legislative aid. As a matter of fact, oftentimes agitation for legislation is in itself a valuable means of public enlightenment. In any event the gains in public opinion should always be fixed as soon as possible in well-drawn laws. Movements, therefore, for legislation affecting medical education, admission to the practice of the profession, the organization of health boards, the enactment of sanitary regulations, etc., should all be regarded as a part of the process by which the expert few and the many are to be brought into relations of mutual respect and good will.

But it remains true that in a democracy, back of the coercive power of the law there lies the social authority which in the long run is vested in the few who by their approved competence and by their spirit of social service command the confidence and respect of the public. With increasing intelligence the many learn to protect themselves against quackery and to place confidence in tested leadership. If the raft of democracy cannot be transformed into a swiftly sailing ship, there is hope, at least, that it may be built up far enough above the waves to carry its passengers dry-shod.

PELLAGRA TREATED WITH SALVARSAN (606)

CHARLES M. NICE, M.D.,
JAMES S. McLESTER, M.D., and GASTON TORRANCE, M.D.
BIRMINGHAM, ALA.

In the light of early and material improvement of symptoms in three typical cases of pellagra following the administration of salvarsan, it has appeared wise to make this preliminary report. The final results, deductions, photographs and later cases will be embodied in a future report.

Case 1.—*History.*—W. H. R., aged 43, white, is an electrical engineer. The patient's family history is negative, except that one sister died some years ago of tuberculosis. The patient had malaria and rheumatic arthritis in youth. Since, he has enjoyed good health until the present condition began. About the middle of January, 1911, the patient was suddenly seized with cramping pains in his abdomen, followed by a profuse and weakening diarrhea. This persisted and did not yield to treatment. Some days later he noticed that his hands were burned to the elbows, which he attributed to hot oil. No similar burn ever occurred, though his work had remained the same. There was also a burn on his thigh, due "to a rent in his trousers." The patient was nervous and cried over small matters. His mouth became sore and he lost weight rapidly. He was confined to bed six weeks.

Examination.—March 4, 1911. The patient was about 5 feet, 7 inches tall, was greatly emaciated and weighed 100 pounds. His expression was dull and he answered questions sluggishly. Pupillary reflexes were normal; tongue red, moist and patchy; lungs were negative; liver two inches below costal margin; abdomen tender; patellar reflex exaggerated. There was a brownish indurated lesion of the skin over the hands and thick crusting over the points of the elbows. The intermediate forearms were pigmented, with paler areas of desquamation. There was also a large encrusted area on the inside of the thigh and the feet were somewhat involved. The urine contained albumin and a few granular casts. The blood showed 6,000 whites, 325,000 reds, 70 per cent. hemoglobin. The stools were six to eight a day, foul, containing macroscopic blood. There were no amebas, hook-worms or other important findings. Von Pirquet and Wassermann tests were negative. The pulse was 108 to 116; temperature slightly subnormal.

Treatment and Course.—After observing the patient two days, and the case being a frank one, it was decided to administer salvarsan (606), which was done by the intravenous method in a 0.05 gm. dose on March 6. There was a rise of temperature to 99.2 F. that evening. Aside from being restless, there was no inconvenience. The following day, the patient said he was better; the bowels had moved only once in twenty-four hours.

March 8, the patient was sitting up in bed and said he was hungry; did not cry when spoken to and looked brighter.

March 9, pulse lowered to 96. The patient knew he felt better. The skin condition had materially faded. The legs showed only a brownish discoloration; exfoliation from the hands marked.

March 12, improvement continued; practically all local signs of the disease had disappeared.

March 15, patient was walking around the ward; had gained weight; said he felt fine and was very hungry. He went home and will return for observation.

CASES 2 and 3.—March 7 and 8, two female negroes, with well-marked pellagra and giving negative Wassermann reactions, were given, intravenously, 0.05 gm. and 0.06 gm. of salvarsan, respectively. An improvement was noted in forty-eight hours.

After a week had elapsed the skin lesions had changed materially as had the ptyalism, vaginitis, weight and mental symptoms. Both were eating heartily, the diarrhea had abated and constant improvement was recorded. There appears to be an early and real improvement with no untoward effects from the administration.

SODIUM CACODYLATE IN TERTIARY SYPHILIS

REPORT OF A CASE *

L. W. CRIGLER, M.D.
NEW YORK

As comparatively few cases of tertiary syphilis treated with sodium cacodylate have been reported, and as widespread interest has been awakened in the treatment of syphilis with arsenical compounds by Ehrlich's new discovery, I wish to report the following case:

History.—J. L., aged 27, presented himself for examination and treatment at the Manhattan Eye and Ear Hospital Sept. 28, 1910, complaining of faucial irritation, for which he sought relief. He was referred to the throat department, where he was examined, and the following history obtained: About June 15 an indurated sore developed on the glans penis just back of the corona, followed in a few days by other sores on the body of the penis. Four weeks later there developed the eruption, followed by the faucial irritation from which he sought relief.

Examination.—The posterior pharyngeal wall was found ulcerated with two or three deep-seated ulcers on the buccal mucous membrane. The skin over the body showed numerous large and small rupial ulcers in various stages of development and necrosis. The patient stated positively that he had never had any other lesion previous to the one reported as occurring ten weeks previously.

Treatment.—A diagnosis of rupial syphilis was made with tertiary manifestations in the throat, and the patient put on bi-weekly injections of salicylate of mercury, together with suitable means for the relief of the local irritation.

Transfer to Eye Department.—After about four weeks' treatment the man was no better, and owing to the fact that a large rupia had developed on the right upper eyelid, with the possibility of its destruction, the patient was transferred to the eye department, where I first saw him on October 19. The diagnosis of rupial syphilis was confirmed by several of my colleagues, and in spite of the fact that the patient had had repeated injections of mercury, the Wassermann reaction was taken and found to be positive. The gumma in the lid was progressive.

Sodium Cacodylate Treatment.—The patient was put on daily injections of sodium cacodylate, ¾ grain to a dose. Within forty-eight hours the surface of the ulcer was smooth and healthy in appearance, the slough having been dissected away. At the end of one week the lid had entirely healed with very little deformity, considering the size of the slough. With the exception of two or three of the larger foci situated on subcutaneous bone surfaces near the skin and elbow, there was rapid cicatrization and healing of the ulcers. At the end of one week the injections were discontinued for a week, at the end of which time a second Wassermann test was negative. The treatment was then resumed in 1½ gr. doses daily for one week longer, after which the man received three injections weekly till November 21,

No internal medication was given until the reaction became negative, when strychnin and iron were given in tonic doses, three times a day. The patient has in no way suffered from the administration of arsenic. The case was apparently a very malignant one. It is possible that some lasting effect of the disease will continue to manifest itself owing to the destructive action of some hidden lesion, and since there are already numerous reports of recurrences after the use of salvarsan, it is not likely that the treatment in this case will completely eradicate the disease. In view of the fact, however, of the non-toxicity of sodium cacodylate, the simplicity of administration, and the rapidity with which it seems to arrest progressive lesions, it should be given whenever the proper administration of salvarsan cannot be carried out.

I hope to be able to report the future progress of this patient at a later date.

57 West Fifty-Eighth Street.

---

* Read before the Ophthalmological Section of the New-York Academy of Medicine, Nov. 21, 1910.

The Anesthetist.—An expert anesthetist is quick to note every change, and can so "nurse" his patient that it is seldom he has any anxiety from the appearance of untoward symptoms. These difficulties may turn up in the hands of the less experienced, who must at times give an anesthetic, and who must, therefore, get the most thorough training possible. No man can have confidence in his power to administer an anesthetic safely who has not a very clear idea as to what constitutes a danger signal and a definite knowledge of how to proceed instantly and without hesitation to get his patient into a safer condition.—W. Rankin, in the *Practitioner.*

SATURDAY, MARCH 25, 1911

MUSCULAR EFFICIENCY AND PAIN

One of the most interesting subjects of discussion in industry and manufactures which has arisen in recent years is the question of human efficiency. In the effort to increase the output in the various trades and crafts a special study of the movements required for various accomplishments has been made. It was shown, for instance, that a bricklayer at work stooped many times a day in order to pick up the bricks. In doing so, each time he stooped he had to support, under varying conditions, the weight of his body and to lift at least one-half of it to the erect posture. On the other hand, it was shown that a good deal of this crude labor with the consequent exhaustion of muscular energy, might be saved by having the bricks so placed that he could reach them without stooping, and that this might be accomplished by means of machinery or scaffoldings, and the employment of cheaper labor than that of the skilled workman. It was found that a man might lay in this way one and a half times as many bricks as he was able to lay by the old method with the expenditure of actually less energy than before. It would seem that this improvement in method, which saved useless movement and expenditure of muscular energy, would surely have been developed by the workman himself; but it was not, and only when a skilled engineer deliberately set himself to study the workman's movements in order to eliminate all those that were unnecessary, was it found how much time and muscle-energy could be saved.

The lesson is rather pertinent for the physician who has to deal with the working classes. It is often found that the source of pains and aches, which are worse on rainy days, and in damp weather generally, and which are therefore usually referred to as "rheumatism," are often the consequence of efforts to use muscles under bad mechanical conditions or in unfavorable circumstances, and then to use them much more than the result aimed at demands. As a consequence of this, in practically all occupations there are painful conditions. In the old days when dentists used foot-power engines, most of them acquired a distinct halt in their gait known to the profession, at least, as the "dentist's halt" or "gimp"; this halt occurred in the leg on which the dentist stood, while the other was used in developing the power. Workmen who are employed on foot-power lathes suffer in the same way, and the only relief for them is to change the foot applying the power, or to occupy a sitting position, from which they can use both feet.

Workmen who are employed at benches in various trades are likely to suffer from corresponding painful conditions of the arms as a consequence of faulty use of the arm muscles. Filers, for instance, who work long hours at filing, are almost sure to have severe aches and pains in their forearms, unless their benches are so low that they can apply from the shoulders whatever pressure is necessary. Men who use a hammer often suffer in the same way, unless care is taken that there is no lost movement or waste of energy in their work. Women who sweep often suffer much more on the right side from painful fatigue (worse on rainy days, and therefore regarded as "rheumatism") than would be the case if they alternated hands in the use of the broom, and changed from a broom to a brush occasionally in order to vary the muscular movements. There is scarcely a trade or occupation in which some of the supposedly inevitable occupation-aches and pains could not be greatly modified for the better by proper direction in the use of the muscles, and by variation in the methods of work. This would save much pain and discomfort and avoid the objectionable use of anodyne drugs. This is the physician's department in the improvement of human efficiency that is occupying so much attention at the present time.

THE FUNCTION OF THE THYMUS

Not least among the problems confronting the physiologic investigator is that presented by the thymus, that mysterious organ which, culminating in its development early in life, normally undergoes early involution and by its persistence not infrequently produces the sudden, so-called thymic death. Friedleben,[1] who attacked this problem as far back as 1858, by attempting to remove the organ from various animals, failed to demonstrate any appreciable physiologic alterations in the animals so treated. Unfortunately, his work was done before the development of aseptic methods and was complicated by infection; nor is it very probable that he succeeded in complete extirpation of the organ. Of the great amount of more recent work, that of Basch[2] stands out prominently, because of the positive results which he reported. Following removal of the thymus in puppies from three to four weeks old, he observed marked, though transient, osseous changes, setting in as early as from two to three weeks after the operation. These changes took the form of deficient ossification with abnormal flexibility of the long bones, and with diminished resistance to fracture, the epiphyseal cartilage being thicker than normal, and at points of fracture there was transitorily deficient calcification of the callus. He obtained also marked nervous changes, the animals showing hyperirritability of the peripheral nerves, and less intelligence than the control animals from the same litter. Occasionally, also, they suffered from convulsive attacks which usually were fatal.

---

[1] Die Physiologie der Thymusdrüse in Gesundheit und Krankheit, Frankfurt, 1858.

[2] Wien. klin. Wchnschr., 1903, xvi, 893; Ztschr. f. exper. Path. u. Therap., 1905-06, ii, 195; Jahrb. f. Kinderh., 1906, lxiv, 285, 1908, lxviii, 649.

Recently Klose[3] has reported the results of a repetition of Basch's work, selecting, however, animals in the height of thymus activity, and not, like Basch's animals, in the period of involution of the organ. By working with puppies from ten to twenty days old, and by observing them over longer periods, he was able to obtain results even more striking than those of his predecessor. The alterations after removal of the organ could be divided with some readiness into several distinct phases. Following an initial latent phase of about two weeks, there came a period of from two to three months characterized by marked increase in adiposity, excessive eagerness for food, and diminished activity and muscular strength. Next came a period of rapid loss of weight, and of muscular and bony strength, although the animals still ate eagerly. Psychically they degenerated until they became practically idiotic. This stage lasted, in different animals, from three to fourteen months, and ended in death preceded by coma. A study of the bones made during the later stages showed marked osteoporosis, with multiple cysts in the spongy parts, and irregular and indefinite limitation of the compact portions. Also there was irregular thickening of the epiphyseal cartilages, and deficient linear growth. Along with these changes, there was a pronounced tendency to spontaneous fracture, followed as a rule by fibrous callus formation only. With the anatomic alterations in the bones there was a corresponding chemical change. While the bones of the control animals showed 65 per cent. of calcium salts, the animals operated on had only from 32 to 34 per cent. This diminution was at the expense of all the calcium salts alike, as the relations between the mineral constituents of normal bone were not altered. The brain also showed definite changes; it was relatively large, and markedly edematous. Klose believes that the changes can all be explained on the basis of an acidosis, acting on the bones by draining them of their lime salts, and acting on the nervous tissues by increasing their affinity for water. In view of the great content of nucleins in the thymus, he believes that nucleic acid may be specified as the offending agent, and regards the thymus as furnishing a site for the synthesis of the nucleins, with accompanying neutralization of the nucleic acid. That there would be an excessive nucleic acid metabolism at the time of greatest growth, corresponding with the period of thymus activity, is self-evident. From the fact that his experimental animals showed at first splenic hypertrophy with later degeneration, Klose concludes that it is the spleen which in later life, after the period of greatest stress, assumes the function of the thymus. Additional support for this view is afforded by the association of hypertrophy of the spleen and lymphoid tissues with that of the thymus in the "status lymphaticus," and by the fact, to which Rachford[4] calls attention, that on exposure of the thymus alone in this condition to the *x*-ray, the decrease in size of the thymus is accompanied by that of the other organs as well. Klose calls attention to the similarity between the osseous findings in his thymectomized animals and those in cases of human rickets and osteomalacia. While at this time no definite rôle can be assigned to the thymus in the production of these diseases, the analogy is too striking not to deserve attention, particularly with diseases of such obscure etiology.

As regards the "thymic death," the conditions shown by surgery seem to justify the conclusion that this is mainly mechanical in character, by pressure on the trachea or large vessels by the enlarged organ. Nevertheless, in view of the pronounced physiologic processes which his work appears to assign to the thymus, Klose believes it probable that altered functional activity plays at least some part in the causation of death. As accessory thymus tissue occurs in the human being in and around the thyroid, and as this is capable of rapid hypertrophy, the surgical extirpation of the organ in the human being in all probability seldom can evoke such results as occur in the dog.

INDUSTRIAL DISEASES

The State of Illinois has recently made an important contribution to the literature of industrial hygiene. About a year ago, the Illinois Commission on Occupational Diseases[1] began its work of investigation and the results of this investigation together with recommendations for the legal regulation of certain dangerous trades have been sent to the governor of the state.

We understand that though other states have made formal inquiry into industrial accidents, Illinois is the first to attempt a study of industrial diseases.

The commission had only about ten months in which to work and wisely decided to make an intensive study of one or two restricted fields, such as that of industrial poisons and of caisson disease, rather than to make a general survey of the whole subject. By choosing the poisonous trades rather than the dusty trades they were able to show clearly the causal connection between occupation and disease. The dusty trades are really the most important numerically considered, but the question of morbidity in these trades is always closely bound up with housing conditions, standard of living, etc., and the influence of the trade itself is less clearly demonstrable. In caisson disease we have a clearly marked trade disease.

---

[4] Tr. Assn. Am. Phys., 1910, xxv, 570.

[1] Report of Commission on Occupational Diseases, C. R. Henderson, secretary, University of Chicago. The commission consisted of the following persons: George Webster, M.D., president of the State Board of Health, chairman; Charles R. Henderson, University of Chicago, secretary; Ludvig Hektoen, M.D., Memorial Institute for Infectious Diseases; Walter S. Haines, M.D., Rush Medical College; W. H. Allport, M.D.; James Simpson, Marshall Field & Co.; and the following state officials: Chief Factory Inspector Edgar T. Davies, Secretary State Board of Health J. A. Egan, M.D.; Secretary Bureau of Labor Statistics David Ross.

The appropriation granted to the commission was expended almost entirely on the field work of investigation, office room being donated by the university and laboratory facilities by members of the commission. Twenty-one investigators were employed, including eleven physicians and ten laymen, the former taking up the hygiene of the different trades and the physical condition of the work-people, the latter investigating factories and examining records of hospitals, dispensaries and sick-benefit societies.

The poisonous industries to which most study was devoted are the lead trades (Alice Hamilton), the brass and zinc trades (Emory R. Hayhurst) and the trades involving exposure to carbon monoxid (M. Karasek and G. Apfelbach), these being important industries in Illinois employing large numbers of workmen. In addition, there are short papers on arsenic, turpentine, the cyanids, hydrofluoric acid, nitrate of silver, metol, platinum, the chromates and chromic acid.

The report on the lead trades shows that this metal is used to an enormous extent in modern industry and that lead poisoning is probably in Illinois, as it has long been known to be in Europe, the most important industrial disease. The list of trades in which lead poisoning was found to have occurred numbers twenty-eight, but the classification of these trades is not very carefully made, and if industrial processes were counted instead, it is probable that the number would come not far from 120, which was Thomas Oliver's estimate of the number of processes in which lead is handled in Great Britain. Several trades are included in this list which the ordinary man does not think of as lead trades. For instance, the making of storage batteries is described as one of the most dangerous; in Europe, this trade is strictly regulated by law. The work of commercial artists is said to involve a fairly large amount of lead poisoning owing to careless methods of using the white paint which the artists suppose to be a harmless zinc white. Apparently physicians are sometimes led astray in their diagnosis of these cases, for their patients assure them that they have never been exposed to lead poisoning, although the investigators found that all but four of the seventy-four engraving establishments visited used white lead paint.

Other unfamiliar lead trades are the making of lithotransfers for pottery, the polishing of cut glass, making and hanging lead-colored wall-papers, enameling bath tubs, and laying electric cables. Five hundred and seventy-eight individual cases with six suspected cases are reported as having occurred in Illinois during the last three years in these twenty-eight trades, but it is stated that this figure represents only a fraction of the real number, for it was impossible to obtain even approximately accurate information as to any trade except the well-organized plumbers, and the partially organized printers and painters. The remaining lead workers are said to be composed largely of newly arrived foreigners "who enter on the work utterly ignorant of its dangers, or with only a vague, unintelligent dread." They are "a notoriously unsteady, shifting class," and "as it is only with a steady force of workmen that the oversusceptible can be weeded out and the others trained to protect themselves, it follows that this shifting of men from place to place is productive of far more poisoning than would occur among a permanent force of men." The investigators find that for the most part very little care is taken of the men employed in the dangerous lead-trades and statistics are given to demonstrate the contrast between European conditions and those in Illinois.

"In one English white lead factory employing 182 men, careful medical inspection failed to discover one case of lead poisoning in the year 1909-10. In an Illinois factory employing 142 men partial inspection revealed twenty-five men suffering from lead poisoning last year. In another English factory employing ninety men no case was discovered for five successive years. In an Illinois factory employing ninety-four men 28 per cent. of all employees have had lead poisoning and 40 per cent. of all employed in the dustier work."

Dr. Hayhurst's report on the brass industry includes a study of "brass-founders' ague," an industrial disease which has been the subject of much controversy in Europe, some authorities even denying that there is an affection peculiar to this trade. The description of symptoms given by Dr. Hayhurst is detailed and clear, but it would be more convincing had he given his personal observation of some one case. Probably the fact that the paper was written for a lay audience made him confine himself to more general statements. He agrees with the generally held opinion that the "ague" is caused by the sublimation products of zinc.

The brass industry in Illinois is apparently in as much need of hygienic regulation as the lead industries, for the prevention of brass-founders' ague seems to be simply a question of the proper removal of fumes. "In large foundries with good ventilation, either natural or artificial, brass chills practically never occur." But the investigators found that only four of the eighty-nine foundries visited could be classed as well-regulated and free from trade sickness, sixty-three were acknowledged to be centers of trade sickness and seven were suspected to be equally bad. Of 189 men from seventy-eight foundries who were examined by Dr. Hayhurst, 146 complained of some sickness traceable to their employment. forty-five had had "brass chills." As brass founders are also exposed to the action of arsenic, antimony, phosphorus, lead and the cyanids, brass ague is not the only industrial disease to which they are subject.

The newly employed men are said to be more susceptible to ague; the older men acquire a certain tolerance, but there is apparently a chronic form of poisoning which shows its effects on the lungs, digestive tract, kidneys and nervous system. Dr. Hayhurst's statistics as to longevity are almost startling. Of 1,761 foundry men, only seventeen were over 50 years of age.

The study of carbon monoxid poisoning is of great interest. Ample material was found in the great steel works of western Illinois where this gas is produced during the smelting of the iron ore with coke and lime. The symptoms of acute poisoning are much like those of ether narcosis, and if the sufferer is rescued in time an apparently complete recovery occurs. Drs. Karasek and Apfelbach undertook to determine the effect of frequent or constant exposure to smaller amounts of gas, chronic carbon monoxid poisoning. For this purpose they examined 240 steel workmen, and found them for the most part in poor physical health and with deficient muscular power, as indicated by the hand dynamometer. A careful control examination made of men of the same nationalities engaged in similar work, but not exposed to gas, showed that the gas workers had actually less muscular strength, a fact which "means a large economic loss in the numerous industries where workers are exposed to carbon monoxid."

Blood examinations of sixty-eight steel workers showed that "in practically all those exposed to blast gas there was a polycythemia numbering between 5,500,000 and 9,600,000. No embryonal or other unusual forms of red cells were present. Seemingly this is a conservative action on the part of the system whereby the harmful effects of the gas are mitigated and great toleration established."

The industrial hygienists of Europe are always reproaching us with our failure to collect data on industrial diseases in the United States. Let us hope that the report of the Illinois Commission will prove to be the first fruits of a widespread effort to make up for our former shortcomings in this respect.

THE NAME "EPINEPHRIN" VERSUS THE NAME "ADRENALIN"

There are thirty or more different brands of the blood-pressure-raising principle of the suprarenal gland on the market, five being in this country alone. These products are identical so far as their chief constituent is concerned; they differ, however as to the solvent and the preservative used. The processes of manufacture of some of them are patented; all of them are sold under trade names.

Until two years ago there was no common name applicable to this active principle; whenever reference was made to it a trade name had to be used. At that time the Council on Pharmacy and Chemistry, realizing the need of a generic term, adopted "epinephrin" as such a term. This name was selected in part because Abel had adopted it in 1899; in part because, so far as could be discovered, it was the name under which, through Abel's publications, the substance first appeared in medical literature; and in part because it seemed to be the only suitable one not already appropriated by some commercial firm.

After the publication of the Council's report, THE JOURNAL began gradually to use the term in those cases in which it seemed clear that the proprietary term was used in a generic sense. The substitution of the name "epinephrin" for "adrenalin" in the abstracts of certain foreign articles caused Parke, Davis & Co. to write a letter of protest which called forth the discussion appearing in the Propaganda Department of this issue.

The amount of space devoted to this matter may be criticized and considered unwarranted by those who do not realize the importance of the subject. The criticism is, to a certain degree, just. The somewhat inordinate length of the article is due in part to the unfortunate fact that, in availing themselves of the courtesy extended by THE JOURNAL, Parke, Davis & Co., in their reply, have injected into the discussion side-issues, such as the priority of discovery, the superiority of their product, etc., whereas, the question under discussion is simply that which relates to the name. It is, however, not altogether a matter for regret that the discussion has been thus broadened, for it brings before our readers many facts regarding the discovery of an important medicinal agent that are not generally known, at least by physicians.

Whether or not "adrenalin" is superior to "adrin," "suprarenalin," "suprarenin," "adnephrin," or to any other of the preparations is entirely immaterial in this connection. The point is that the active principle of the suprarenal gland is on the market under various trade names, and that a name common to all has been selected to be used when no particular brand is referred to. The fact that "adrenalin" is regarded by many, both here and abroad, as a common, generic name does not alter the fact that it is claimed as a trade name by a commercial house and, therefore, presumably at least, cannot be used except as such.

Among the facts brought out in this discussion, one stands out clearly: that Abel deserves as much credit for the discovery as any other man, if not more. Credit belongs to Takamine for making use of reactions which were already well known. His work was a step in the progress of knowledge of the substance, but it was a step which he could not have taken but for what others, Abel especially, had accomplished and published. Abel's magnificent work, covering several years, deserves as much credit, to say the least, as that of Takamine. And it should be kept in mind that the former worked in the interest of science, and published his results for the benefit of all. He had no hope of pecuniary reward, asked for none, and received none.

Let us repeat, however, that these are side issues; the question is simply that of name. It cannot be too strongly emphasized that "epinephrin" is a true scientific name for the active principle of the suprarenal gland, and that it should be used on all occasions when the active principle and not some particular firm's make is referred to.

Current Comment

A FIFTH YEAR AS A HOSPITAL INTERN

Probably the next important advance in medical education will be the requirement of a fifth year to be spent by the student as an intern in some good hospital. In the majority of our better colleges even now most of the graduates are obtaining internships and it is claimed that there are more opportunities for such positions than the colleges are able to fill. It is also stated that the students who do not accept such internships, as a rule, are the very ones who should be required to take that work. Therefore, the requirement of the fifth year as a part of the course for the medical degree, in such institutions at least, could easily be brought about. In some states, however, where colleges have desired to make this additional requirement, they cannot do so because of the wording of the medical practice acts. In these states the law provides that only graduates of medical colleges may obtain licenses and that only licensed physicians can serve as interns in hospitals. Thus the colleges are unable to withhold the degree until after the fifth year is completed. A way out of this difficulty would be to secure an amendment to the medical practice act such as is being sought in Illinois. This amendment provides that the board in its discretion can admit to its examination a student who presents a certificate from a reputable medical college, showing that he has completed four years in medicine and has passed the examinations of that college. If it should be considered necessary or advisable, the state board could issue a limited license authorizing him to practice medicine and surgery in a hospital, this limited license to remain in effect for a period not exceeding eighteen months and to be exchanged for the permanent license as soon as the student has completed his internship and obtained his M.D. degree. Surely, an arrangement of this sort would in no way lower the standards of medical licensure in any state; on the contrary, it would strengthen the practice act and aid in securing better qualified physicians. The time is rapidly approaching when no one should enter on the practice of medicine without first having completed a year of clinical training under the direction of the attending staff of some good hospital.

POSITIVE RESULTS OF SANE FOURTH AGITATION

Over eight years ago, THE JOURNAL published its first report, showing that as a result of the use of fireworks in the celebration of the Fourth of July in that one year, 466 persons were killed and nearly 4,000 injured. Of those killed, over 400 died from tetanus, probably the most awful death known in modern times, while of those injured, many of them were blinded, or had their arms, legs, hands or fingers torn off, or were otherwise mutilated for life. For a few years previously a prominent newspaper, the *Chicago Tribune,* had been publishing, as a news feature, the immediate results of the celebration, but the complete figures, including the deaths from lockjaw, were not presented until in 1903 THE JOURNAL published its first report. This report, awful as it was, scarcely disturbed the self-complacency with which these matters then were viewed, and apparently any criticism of the methods of celebrating the anniversary of the signing of the Declaration of Independence was looked on as unpatriotic. But year after year THE JOURNAL has persisted not only in revealing the horrifying results of the use of fireworks, but also in pointing out how silly and inexcusable was a "patriotism" which demanded each year such a wanton destruction of life and limb. Gradually, however, results began to be seen. At first a few cities adopted prohibitive or restrictive measures with such positive reductions in the number of killed and injured that other cities have followed suit. The most positive evidence of the nation-wide movement for a sane celebration and for the lessened use of fireworks, is the dissolution of the Pain Manufacturing Company, the largest and best known fireworks firm in the country. Here is what the firm says regarding its failure:

> The season for the business conducted does not commence until June and runs for several months; the main business is done around and immediately previous to the Fourth of July each year. For the last years, or since the movement for what is commonly termed the "sane Fourth" has spread over the country, the value of the business done by the company has been reduced, so that at the present moment the amount of business the company is enabled to do is not sufficient to warrant the company's continuance.

Although one may have sympathy for those who have lost money or fortunes in the failure of this business enterprise, there is reason to rejoice, nevertheless, in the change of sentiment regarding the use of fireworks in our celebration which means, in future, the saving of thousands of lives, the prevention of many thousands of accidents and the saving from destruction by fire of property worth millions of dollars. It is gratifying to note, also, that instead of being continued as a hideous nightmare of disorder, danger and tumult, our Independence Day is being changed into a day for the development of genuine patriotism—respect for law and order, and pride in our national achievements.

NEITHER CLEVER NOR TRUTHFUL

The attempts of the lay press to comment on medical subjects are often most amusing when most seriously intended. Enjoyment of the unconscious humor in otherwise rather feeble witticisms like some which have recently appeared in *Life,* is hampered by the fact that these gibes at medical science are sometimes not only absurd, but viciously and maliciously untruthful, and if they were seriously regarded, might result in public injury. For instance, *Life* comments as follows on the recent report that a Russian physician had committed murder by the use of diphtheria germs:

> "Why, in the name of common sense, didn't he employ typhoid fever 'germs' in the pretense of immunizing the count from ever having that disease, as our army surgeons are doing with all soldiers and sailors who 'volunteer'—under the pressure of the anger of their superior officers in case of refusal? Every such inoculation makes the lads ill ('reaction' is the technical term), and occasionally one of them will pass on, as the saying goes."

The item is headed "Not Clever." It should have been "Neither Clever nor Truthful." *According to the* surgeon-general of the Army, about 20,000 antityphoid inoculations have been made in the Army of the United States. Of these, 85 per cent. caused no disagreeable symptoms whatever; 4.5 per cent. caused headache and slight temporary fever; and 0.5 per cent. more severe symptoms lasting several days; but in not a single instance has the procedure had any effects that could be called dangerous. There has been no death from this cause. The protective results of antityphoid vaccination in European armies, especially in the British army in India, have been so favorable as to warrant the continuance of inoculation. The comments of *Life* show glaring ignorance. We do not expect scientific accuracy from that publication, but even clowns should strive to keep within the bounds of common honesty by being truthful when they attempt to deal with serious matters, especially those which have a practical bearing on the public welfare.

AN "ALL-ROUND SPECIALIST"

Few there are who have looked to see a reincarnation in these days of the sage who took "all knowledge for his province." Viewing the vast and hitherto undreamed-of realms brought to human cognizance by specializing discoverers, timorous souls have believed—and the belief has become all too general in learned circles—that the complete mastery of even the complex science of medicine in all its divisions and branches was not to be expected of one human brain. It is now plain to be seen that we have despaired too soon. A prodigy has arisen in the west who announces himself on his letter-heads as an "All-Round Specialist." We should like to feel that the nursery of genius which produced the "All-Round Specialist" was engaged in fostering others of the same remarkable stock. We should then hear no more of the much-vexed problem of the division of fees between the specialist and the general practitioner, while the tedious distinctions between psychiatrist, ophthalmologist, pediatrist, gynecologist, dermatologist, and all the other medical specialists, would melt away like mist before the morning sun. Unfortunately, we are unable to find this gentleman's name on the alumni list of any medical college; so we fear that there is no hope for the present of a school of pan-specialists.

PROFESSOR VINCENT AND HIGHER EDUCATIONAL STANDARDS

If all statements appearing in the public press may be judged by those regarding the recent address by Prof. George E. Vincent,[1] then, indeed, very little confidence should be placed in newspaper reports. By quoting only the first part of a paragraph, the reports made it appear that Professor Vincent opposed higher standards of medical education, although a reading of the entire paragraph shows that the opposite is true. In fact, the address as a whole contains a severe arraignment of those who are opposing higher standards. Professor Vincent points out that one danger in raising educational standards—namely, limiting "the field of choice to those groups which can afford the cost of long and expensive preparation," which "socially and professionally . . . would be deplorable"—could be offset by establishing "a system of scholarships" which could be "awarded by competent authority, after adequate tests, and continued only so long as the scholar's work justifies the support." It can be seen how easily a wrong impression could be conveyed by omitting the latter part of the paragraph. And that is what was done in the newspaper reports. This misquotation might have passed without comment, except for two reasons. The first is that Professor Vincent is soon to take the presidency of the University of Minnesota and, therefore, his views will have much to do in shaping the future educational policy of that state. The second is that Minnesota is on the firing-line in the fight for higher standards of medical education, and the enemies of such standards have widely circulated this erroneous report of Professor Vincent's views in an effort to obstruct the movement for higher standards. In the paragraph just preceding the one misquoted, the speaker makes special reference to those who are opposing higher standards of medical education. He shows these to be self-interested persons who look on the "medical career chiefly as a means of livelihood," and who "resent the rising standards . . . as obstacles to the early enjoyment of an income." It is important that this misquotation should be corrected, and especially that the people of Minnesota should appreciate the fact that in Professor Vincent they will have an able champion in their battle for higher standards of medical education.

STREET DUST AND FOOD

House Bill 154, now before the Illinois legislature, contains some provisions which will scarcely be welcome to street vendors of goods and delicacies, and probably not to the larger retail dealers. Among these are provisions to suppress the nuisance of the exposure on the streets, without protection from the street dust or other contamination, of fruits, vegetables and other foods. It is unfortunate that the average buyer has not that keen realization of the history and composition of street dust which, if generally diffused, would make goods so exposed unsalable. On the contrary, dealers complain that their sales are lessened if they do not so expose their wares. Instruction in the schools, showing the sources and components of street dust, as well as the peril of insect contamination, might be an effective way of agitating the subject and reaching homes where at present even newspapers do not penetrate freely—not that the illiterate are the only persons who ignore the dangers of street dust. To make them effective, the excellent provisions of this bill should be reenforced by popular education, since it will be most difficult to enforce in those quarters where enforcement is most needed.

Fibroids and Pregnancy.—A fibroid projecting into the uterine cavity—that is, a fibroid inside of the uterus—usually acts as a barrier to pregnancy, and if this does occur an abortion is likely to follow.—M. A. Tate, before Obstet. Soc. of Cincinnati.

---

[1] Standards and Authority, p. 894, this issue.

Medical News

ILLINOIS

Personal.—Fire at Abingdon, March 11, destroyed the office equipment of Drs. Charles F. and Everett H. Bradway, the loss being estimated at $1,000.——Dr. Barret B. Griffith, Springfield, who has been in Colorado Springs for several months on account of ill health, reports that he is slowly recovering from the injury to his foot.

Hospital Notes.—The John Warner Hospital, Clinton, is open for the reception of medical and surgical cases. Patients entering the hospital will be under the control of their own physicians as the hospital has no attending staff.

Chicago

Healer Fined.—A jury in the municipal court, on March 14, is said to have returned a verdict assessing a fine of $200 against Mrs. M. Selike, a Milwaukee Avenue healer.

Personal.—Dr. Svenning Dahl, while attempting to get into a moving elevator at the Norwegian Lutheran Deaconess Home and Hospital, March 14, fell, sustaining a compound fracture of the right leg.

INDIANA

Tuberculosis Hospital Almost Ready.—It is announced that the State Tuberculosis Hospital, Rockville, will be ready to receive patients, April 1.

Dispensary Opened Twice a Week.—It is announced that the Free Dispensary of St. Mary's Hospital, Evansville, will now be open on Tuesday and Friday afternoons between 3 and 4 o'clock.

Semi-Centennials.—Dr. Carter H. Smith, Lebanon, was the guest of honor at a banquet given by the Boone County Medical Society, March 7, on the occasion of his completion of half a century in the practice of medicine.——The semi-centennial of the practice of medicine of Dr. William B. Graham, Noblesville, was celebrated, March 14, at a banquet tendered Dr. Graham by the Hamilton County Medical Society.

Personal.—Dr. and Mrs. Bleeker J. Knapp, Evansville, sailed for the Mediterranean, March 4.——Dr. Orange G. Pfaff, Indianapolis, who has been seriously ill with septicemia, is now reported to be improving.——Dr. John S. Whitson, Jonesboro, was thrown from his automobile when it was struck by a trolley car, March 15, but sustained only slight injuries.——The trustees of Indiana University have acted favorably on the request of Dr. Henry R. Alburger of the medical department, to come to Indianapolis and assume the position of pathologist at the City Hospital.——Dr. David H. VanNuys is reported to be seriously ill at the home of his son in Anderson.——Dr. Charles S. Goar, Indianapolis, while crossing the railroad tracks, March 17, was struck by a switch engine, but was not seriously injured.

MARYLAND

New Officers Elected.—The section on Neurology and Psychiatry of the Baltimore City Medical Society, at its annual meeting, March 10, elected Dr. Arthur P. Herring, president; Dr. G. Lane Taneyhill, secretary, and Dr. William R. Dunton, a member of the executive committee.

Personal.—Dr. H. Barton Jacobs sailed for France, March 18.——Dr. William H. Welch has been honored by the emperor of Germany with the decoration of the royal crown of Prussia, second class.——Dr. Christopher Johnston, professor of Egyptology in Johns Hopkins University, is ill with organic heart disease.——Dr. George F. Speicher, intern at the Maryland General Hospital, was operated on at the hospital, March 6, and is reported to be doing well.

The Recent Diphtheria Epidemic.—Dr. William H. Welch, professor of pathology in Johns Hopkins University, delivered an address to the medical students in Hopkins Hospital, March 13, in which he reviewed the recent diphtheria epidemic. He stated that of the sixty-three persons who gave positive cultures, about forty showed symptoms of the disease, while the others were carriers. There were only two deaths, both in cases of children who were already victims of malignant disease. Dr. Welch complimented the hospital staff on the energetic way with which the diphtheria epidemic had been handled. No new cases have developed at the Johns Hopkins Hospital or at the Church Home and Infirmary, and these institutions as well as the Hebrew Hospital are open as usual. A case developed, March 15, at University Hospital, but the patient was promptly isolated and no other case occurred. Two cases have also been reported among the lodgers at the Central Young Men's Christian Association, but the patients were promptly sent to the Infectious Disease Hospital.

MICHIGAN

Antituberculosis Society Organized.—Manistee County Antituberculosis Society has been organized with Prof. S. W. Baker as president, and Dr. Szymon Szudrawski, Manistee, as secretary, and has begun an organized campaign against the disease. Dr. Alfred S. Warthin, Ann Arbor, will deliver two lectures before the society in April.

Personal.—Dr. Charles A. Walsh, Bay City, is reported to be in a critical condition from cerebral hemorrhage.——Dr. Herbert A. Eades, Bay City, was thrown from his automobile, March 13, receiving bruises and cuts.——Dr. Robert H. DeCoux, Grand Rapids, was thrown from his buggy in a runaway accident, March 8, fracturing three ribs and a clavicle.

State Sanatorium.—Admission to the State Sanatorium, Howell, is obtained after examination by physicians appointed for each county, and on furnishing a certificate by the family physician. A charge of $7.00 per week is made to those who are able to pay, but those who are unable to pay will be provided by the state with free care on proper certification from the superintendent of the poor and the judge of probate. No patient is allowed to remain longer than six months in the sanatorium save in unusual cases. It must be understood that the institution is for patients in the incipient stage of pulmonary tuberculosis, and in which a cure or arrest may be hoped for.

MINNESOTA

Interns Leave Hospital.—Three interns at the Swedish Hospital, Minneapolis, resenting the suspension of another intern, are said to have abandoned their work and left the hospital, February 25.

Speed Parting Guest.—Dr. Edward M. Gans, Eveleth, was the guest of honor at a dinner given, February 28, at which about 100 were present. Dr. Gans has severed his connection with the More Hospital and is about to move to North Dakota.

Deficiency Appropriation.—The senate committee has recommended that deficiency appropriation of $13,000 be made to enable the State Board of Health to continue its fight against tuberculosis.——The bill to appropriate $8,000 for the continuance of the work of the State Tuberculosis Commission was recommended for passage by the Senate Committee on Public Health, March 3.

NEW YORK

Medical Women Meet.—At the fifth annual meeting of the Women's Medical Society of New York State, held March 10, in the Academy of Medicine, New York City, Drs. Elizabeth M. Cushier, Manhattan, and Eliza M. Mosher, Brooklyn, delivered memorial addresses in honor of the late Drs. Elizabeth and Emily Blackwell. The following officers were elected: honorary president, Dr. Eliza M. Mosher, Brooklyn; president, Dr. Grace Peckham Murray, Manhattan; vice-presidents, Drs. Helene J. C. Kuhlmann, Buffalo; Angenette Parry, Manhattan, and Evelyn Garrigue, Millbrook; secretary, Dr. Eveline P. Ballintine, Rochester, and treasurer, Dr. Marion Craig Potter, Rochester. A banquet was given to the visiting delegates in the evening, over which Dr. Eliza M. Mosher presided.

Buffalo

Hospitals Opened.—The Ernest Wende Hospital, the temporary municipal hospital for contagious diseases, which has been renovated and newly equipped, is ready to receive patients.——The new contagious disease pavilion of the Children's Hospital is completed and ready to receive patients.

Personal.—Dr. Francis C. Goldsborough, formerly instructor in obstetrics at Johns Hopkins University, Baltimore, has succeeded Dr. Matthew D. Mann as professor of obstetrics at the University of Buffalo.——Dr. Archibald D. Carpenter has been elected chairman of the Civil Service Commission.——Dr. John D. Howland, deputy medical examiner of Erie County, has been appointed superintendent of the Erie County Hospital, vice Dr. Carroll J. Roberts, who has gone abroad.——Dr. Pierce J. Candee is ill with typhoid fever.——Dr. George B. Stocker has been appointed deputy medical examiner of Erie County.——Dr. Daniel V. McClure has been certified by the State Civil Service Commission at the head of the list of successful candidates at the recent competitive examination for medical superintendent of Erie County Almshouse.——Dr. Edward J. Meyer, who was operated on for hernia and appendicitis at St. Mary's Hospital, Rochester, Minn., February 13, is convalescent.——Dr. William H. Mansperger, who was recently operated on at St. Mary's Hospital, Rochester, Minn., is reported to be convalescent.

New York City

Middleton Goldsmith Lecture.—The Middleton Goldsmith Lecture of the New York Pathologic Society was delivered at the New York Academy of Medicine, March 18, by Prof. Frank P. Underhill, Yale University, on "A Consideration of Some Chemical Transformations of Proteins and Their Possible Bearing on Problems in Pathology."

Personal.—Dr. John N. Beckman, a retired practitioner, was knocked down by a truck at East Fourteenth Street, March 13, and painfully injured.——Health Commissioner Lederle returned from a vacation in a houseboat in Florida, March 12. ——Dr. Robert S. Adams, house physician at the Waldorf-Astoria, is reported to be seriously ill at Murray Hill Sanitarium.——Dr. Burt D. Harrington, Brooklyn, is reported to be critically ill with erysipelas.——Dr. Godfrey R. Pisek has been appointed attending physician to the Willard Parker Hospital.

For the Control of Venereal Diseases.—At the meeting of the New York Obstetrical Society, held March 14, the subject for the evening was "Some of the Duties of the Gynecologist to the State and Public." The following resolution was adopted: Resolved, That it is the opinion of the New York State Obstetrical Society that the time has come to make a beginning in the control of venereal diseases: That the first necessity is for the provision of a place for the detention and care of flagrant and especially dangerous cases: That in pursuance of this object the Board of Estimate and Apportionment be requested to grant the request of the Board of Health for the provision of such a hospital.

Meningitis on Liner.—The Greek steamship *Patris* arrived at quarantine with five cases of cerebrospinal meningitis. Six other passengers died from the disease at sea. Dr. Alvah H. Doty said that for several years he had been watching for this disease and had found that as a rule it is brought on steamships from Greece.——On the steamship *Martha Washington*, which arrived a few days later from Trieste, Patras, Palermo and Algiers, there were four steerage passengers who seemed to be suffering from cerebrospinal meningitis and one passenger had died at sea whose symptoms were those of meningitis. All the patients were treated with Flexner's serum and the steamer will be held at quarantine until bacteriologic examinations have been made.

Health Bulletins.—The first of the three latest press bulletins of the Department of Health deals with fresh air, which is a great preventive of many infectious diseases, and states furthermore that the polluted atmosphere of ill ventilated rooms is one of the important factors in promoting the spread of diseases; the second warns the public, particularly those living on the lower East Side, against the danger from the use of wood alcohol which is mixed with cheap drinks by certain unscrupulous and criminal proprietors of barrooms and itinerant venders; and the third, details the work of the department in the supervision of midwifery, and states that out of 129,031 births reported in the city in 1910, 52,010 were under the care of midwives. Since February 15 a new system has been inaugurated and put in effect by the Division of Child Hygiene. The city has been divided into 140 districts, corresponding to the school inspection districts, each under the charge of a medical inspector. Each inspector has a card index of each midwife in the district, and visits each midwife at least once a month. Any irregularity in equipment or manner of work of the midwife, or any insanitary condition in their homes is at once reported by the inspector. Investigations are made in all cases in which complaints are made.

Announcement of the Monthly Bulletin.—The ultimate object of all public health work is the preservation of health and the prolongation of life. As there can be no subject of more vital interest to each individual, the Department of Health desires the cooperation of every citizen, and presents the Bulletin as a means towards this end. It was interesting to note a steady fall in the death-rate from 28 per 1,000 in 1868 to 16 per 1,000 in 1910. From another table it was interesting to note the enormous reduction in mortality which had taken place in those whose ages were below 45; there had been no decline but an increase in the mortality in the ages over 46. While there has been a decided reduction in the mortality from smallpox, typhoid fever, diphtheria and pulmonary tuberculosis, there has been but little change in the mortality from measles, scarlet fever and bronchitis, and there is an increase in that from pneumonia, cancer, Bright's disease and heart disease. The division of communicable diseases is charged with (a) the sanitary supervision of tuberculosis, typhoid fever, cerebrospinal meningitis, malaria, puerperal septicemia, abortion and erysipelas; (b) the conduction of tuberculosis clinics and boat camps; (c) the administration of antitoxin and the performance of intubation in diphtheria; (d) the management of the diagnosis laboratory, and the collection of specimens from branch stations throughout the city. The division of child hygiene has the following functions: (a) the control of the practice of midwives; (b) the supervision of foundlings; (c) the supervision of day nurseries and institutions for the care of dependent children; (d) the care of babies and prevention of infant mortality; (e) the medical inspection of and examination of school children; (f) the issuance of employment certificates.

PENNSYLVANIA

Personal.—Dr. John W. Beckett, Pittsburg, was struck by a trolley car, March 10, and seriously injured.——Dr. William M. Johnson, a retired practitioner of Harrisburg, is said to have been adjudged insane by the county court of Davidson County, Tenn.

New Medical Club.—The physicians of York have organized the York Medical Club with an initial membership of forty-five, and elected the following officers: president, Dr. Edward W. Brickley; vice-president, Dr. Lawton M. Hartman; secretary, Dr. William S. Weakley, and treasurer, Dr. Parker N. Wentz.

White Haven Report.—At the annual meeting of the White Haven Sanatorium Association, held March 13, Dr. Lawrence F. Flick, the president, announced the completion of an administration building, the completion of which added $11,000 to the debt of the association, making a total debt of $25,000. Last year 552 patients were admitted and a total of 683 patients treated. Of these 477 left or were discharged and there were 38 deaths. The report also showed that in 31 cases the disease was arrested; in 50 cases much improved; in 254 improved; of the other patients, 106 were not improved and one-third of these left the first month. The average cost of maintenance per patient per week was $8.81 and the total amount expended for maintenance was $67,282.99. The total receipts, including the balance for last year, was $112,000. The total expenditures for the year were $109,487. There was a loss of nearly 12 cents daily in the maintenance of each patient. There are 206 beds available for patients, of whom there have been 5,550 since opening. A building has been donated by Mrs. Eckley Coxe for the care of patients received in a dying condition.

Philadelphia

Medico-Chirurgical's New Building.—Plans are being prepared for several new buildings for the Medico-Chirurgical College, to be built on the south side of Cherry Street, between Seventeenth and Eighteenth Streets. The first building will be a one-story structure with a glass roof to be used for laboratory purposes. A fifth story will also be added to the present dispensary building on Cherry Street. Plans have been completed for the erection of a large corrugated-iron building on the lot adjoining the Medico-Chirurgical Hospital. The first use to which the addition will be put will be a bazaar and fair, to be held from May 29 to June 3 for the benefit of the hospital.

Personal.—Dr. George E. deSchweinitz announces that there is no basis for the rumor that he intends to resign the chair of ophthalmology in the Medical School of the University of Pennsylvania.——Dean Allen J. Smith, of the University of Pennsylvania, closed a series of popular health lectures, given under the auspices of the medical faculty, March 17. His talk was on "Flies and Other Insects as Carriers of Disease."——Dr. L. Webster Fox, who has been ill at his home in Haverford, is convalescent.——Dr. W. E. Kepler has been appointed an assistant medical inspector by Director Neff of the Department of Health and Charities.——Dr. Joseph S. Neff, Director of Public Health and Charities, who was injured by a fall in Atlantic City, March 13, has completely recovered.

VIRGINIA

New College Building.—It is reported that the University College of Medicine, Richmond, has placed the contract for the erection of a new college building to replace the one destroyed by fire in January last year. The new building will cost about $135,000, and will be completed within a year.

Epileptic Colony.—The recent decision of the state supreme court against the Western State Hospital board in its efforts to retain the Muckland property, Lynchburg, means that the property may be sold and the proceeds used for the development of the State Epileptic Colony, which already has been opened with 100 inmates.

Station at Sanatorium.—The Norfolk and Western Railroad has ordered a station to be erected at the Catawba Road crossing for the accommodation of patients and others en route to the State Sanatorium. The company has also put on an extra train on Tuesdays and Fridays for Catawba, which will meet the main-line trains.

WISCONSIN

Cottages for Isolation Hospital.—The city council of Racine has reported favorably on the appropriation for the construction of two cottages on the Isolation Hospital property south of the city for the care of individuals suffering from communicable diseases.

Personal.—Dr. John B. Spaulding, health officer of Kenosha, sustained severe injuries to his eyes by the breaking of a bottle of formaldehyd which he was using while making a fumigation.——Dr. Henry T. Brogan, city physician of West Allis, who has been critically ill with heart disease, is reported to be out of immediate danger.——Dr. Henry Blank, Milwaukee, has been appointed a trustee of the Johnston Emergency Hospital, vice Dr. Louis Fuldner, resigned.——Dr. Rollo U. Cairns, River Falls, has returned from abroad.——Dr. Gilbert E. Seaman, Milwaukee, has been appointed regent at large for the Milwaukee University.

LONDON LETTER

(From Our Regular Correspondent)

LONDON, March 11, 1911.

A New Reportable Disease

The London County Council has issued an order making ophthalmia neonatorum a reportable disease. Thus, as in cases of the specific fevers, immediately on diagnosis a case must be reported to the health officer. The object is that more effectual means may be taken for its prevention and treatment.

Plague in India

According to the latest reports, there seems every indication that India is again entering on another grave epidemic of plague. During the week ended February 11, 24,715 cases and 22,278 deaths were reported. Of these deaths 11,116 occurred in the United Provinces. In this district the deaths during the whole of 1908 amounted only to 22,878 and during 1909 to 38,298.

Economic Entomology

The recent discoveries of the important part played by insects in the propagation of tropical diseases has caused much attention to be devoted to entomology, particularly economic entomology, in Great Britain, which has such extensive tropical possessions. At the Imperial College of Science and Technology, South Kensington, a course of studies in practical entomology for the training of young students has been inaugurated. The objects are to stimulate interest in the study of noxious insects throughout the tropical colonies, and thus gradually to organize an army of collectors and observers who will accumulate the material necessary for coping with the numerous pests which cause disease and devastate crops. The work has been placed under the control of Mr. Maxwell-Lefroy, imperial entomologist to the government of India.

Mr. Andrew Carnegie has agreed to pay for three years the expenses of sending three or four young men to the United States to receive a thorough training in the methods of dealing with noxious insects. At present, two traveling entomologists, appointed by the government, are traversing the whole of the British colonies in tropical Africa, and have received instructions to supply any official or resident with apparatus for the collection of specimens of noxious insects, and to give practical instructions. A preliminary survey has already been made of Nigeria, Nyassaland and part of British East Africa. Considering the paucity of the white population the number of men who have volunteered to assist in the work is highly creditable.

The Outbreak of Small-Pox

Since the outbreak of small-pox in London was reported in THE JOURNAL, March 18, fresh cases have occurred almost daily. There are now 42 patients under treatment and nine deaths have taken place. The disease has spread from the district of Mile End over a large part of the East End and has invaded part of the West and South. The question of the condition of the patients as regards vaccination is interesting. Seven children under the age of 8 have been attacked, of whom only two are said to have been vaccinated. These two d the disease in a very mild form and hardly seemed ranged in health. On the other hand, of the other unvaccinated five, four died. Of fourteen patients between the ages of 8 and 30 years, three had never been vaccinated and eleven were vaccinated in infancy; none had been revaccinated. Of thirteen patients between ages of 30 and 60 all had been vaccinated in infancy, but none had been revaccinated; two died. Two of three patients over 60 died; they had all been vaccinated in infancy, but none had been revaccinated. Thus no case has so far occurred in a revaccinated person.

PARIS LETTER

(From Our Regular Correspondent)

PARIS, March 3, 1911.

Antityphoid Vaccination

The Académie de médecine adopted the conclusions of Dr. Vincent's report (THE JOURNAL, Feb. 25, 1911, p. 601), put in the form of a motion, recommending the facultative employment of antityphoid vaccination. In the draft of the budget of the war department for 1911 is a provision of $3,000 (15,000 francs) for the organization of a service of antityphoid vaccination to be annexed to the laboratory of the hospital connected with the school of Val-de-Grâce. Once installed, this service will cost annually about $600 (3,000 francs).

The Study of the Gastric Secretion at High Altitudes

On ascending to high levels anorexia is commonly experienced, generally accompanied by nausea and vomiting, of which the relative deprivation of oxygen is the most apparent cause. Dr. Raoul Bayeux of Paris has just communicated to the Académie des sciences the results of a series of experiments which he undertook on Mont Blanc to elucidate the mechanism of this anorexia by studying in a dog which had a gastric fistula the variations caused by the high altitude (4,360 meters, or over 14,000 feet), in the quantity of gastric juice secreted and its total acidity. He has ascertained that the quantity of gastric juice secreted in a given time after identical meals diminishes notably during sojourn at high altitude; the total acidity of this juice is only slightly diminished under the same conditions. The rate of secretion of the gastric juice is much retarded. This decrease of the secretory activity of the stomach is in harmony with the diminution of combustion already noted by Dr. Bayeux at the same altitudes. The insufficiency of gastric juice explains the loss of appetite. It also seems to explain the desire which is felt at very high altitudes for all foods capable of exciting the flow of gastric juice or supplying its place, such as lemon juice, vinegar and spices.

Internships Reserved for Women

A notice recently placed in the walls of the hospitals and of the Faculté de médecine aroused considerable interest among the students. It is in regard to the *concours* for the internship of the national asylum for convalescent women in the suburbs of Paris. The administration states that since the hospital is for women it seems to be appropriate to reserve th internships for women students alone.

Glycerin and Potassium Permanganate Cause Fire

In some military maneuvers, recently, a bottle of glycerin was broken and the glycerin ran over some packets of permanganate of potassium. These packets were covered with absorbent cotton, which took fire. Experiments show that chemical reaction takes place, with explosion and fire. It is therefore important to avoid packing glycerin and permanganate of potassium near each other in sanitary stores.

BERLIN LETTER

(From Our Regular Correspondent)

BERLIN, March 2, 1911.

Personal

Professor Bernstein, director of the physiologic institute at Halle, will resign his teaching position at the beginning of the winter semester on account of advanced age.

Progress in the Care of Youths by the Prussian Government

According to an order of the department of education, dated January 18, the Prussian government will undertake the care of youths, that is, the intellectual, moral and physical welfare of young men from the time of leaving school until their period of military service. The associations already existing for this purpose will receive aid and new ones will be formed under the auspices of the authorities, and an appropriation of $250,000 has been made by the government for the purpose. The aims are to promote physical exercises (gymnastics, active sports, tours, etc.), encouragement of nature study, instruction in scientific and hygienic subjects, etc. The cooperation of physicians in the fulfilment of this task is very much desired by the minister.

Failure of the British Government to Take Part in the International Exposition of Hygiene at Dresden

While almost all of the civilized nations have already indicated their intention to send official representatives to the international exposition of hygiene at Dresden and to establish special national sections, the British government declined some time ago to participate. In the British House of Commons the minister of commerce was asked a short time ago the reasons for this decision. His answer was that the department of commerce had been required to furnish an official British section in the expositions at Brussels and Buenos Aires in 1910 and in the expositions at Rome and Turin in 1911. In consequence of these frequent demands on British industry for representation at expositions, the department of commerce was not able to take part in the organization of a section at Dresden. We are convinced that not only the British government but British trade will be little satisfied with this short-sighted position taken by the minister of commerce, for in the competition between the nations, which promises to be very lively at the Dresden exposition, Great Britain will play a quite unsatisfactory rôle.

Tuberculin Treatment of Railroad Employees

The pension office for the employees of the Prussian railroads is from now on to permit those patients with pulmonary tuberculosis, who have finished a treatment in one of their sanatoria, to be treated in an ambulant way with tuberculin by the physicians of the office if the sanatorium considers this desirable for a permanent cure. The tuberculin treatment, which is restricted to special cases, is carried out according to suitable regulations under careful directions of the sanatoria. Further, the pension office provides courses of instruction in two sanatoria for railroad surgeons on tuberculin treatment.

Railway Car Hygiene

A short time ago a representative in the Prussian parliament called attention to the imperfect hygiene of railway cars. He cited a case in which a member of parliament had evidently acquired a severe skin disease from the upholstered back of his seat during a railway journey. The member of parliament, therefore, wants the railway management to adopt for trial some apparatus for protection of the head and neck to be applied to the upholstered back of the seat. He recommended an apparatus in which protective strips of Japanese crêpe paper are so arranged that the passenger can draw out a strip to place under the head and neck. We scarcely believe that the railway management will adopt this recommendation, which would be quite expensive and which could not be guarded against abuse. Protective coverings for the head in railroad travel are already for sale and can be provided by anyone at slight expense.

Association News

TRAINS TO LOS ANGELES

Details of Special Trains and Special Parties Arranged for the Trip to the Next Annual Session

For many weeks past there have been printed in this department of Association News various details concerning the Los Angeles session and the trip thereto, viz., lists of meeting places, a schedule of hotels and rates, railroad rates, etc. (The eastern rates have not been announced; they will be given in these columns as soon as the information can be obtained.) Announcement has also been made that early in May there will be a special issue of The Journal reiterating all this information and giving also the program of each Section and much other information such as is usually gathered into this annual special number. It will contain a map of Los Angeles and many fine pictures of that city.

In attending this session a wonderful opportunity is offered for a vacation that will be not only a pleasurable one, but also a profitable one. The amount of pleasure and profit to be gained by the trip, however, will depend on whether the individual has studied for himself the opportunities presented.

Below are given in brief accounts of some of the special parties that are being arranged. But no one will depend alone on this description. Everyone who is thinking of going to Los Angeles should write for booklets and information to all whose addresses are given in the following itineraries. If these books are studied, one can obtain a general knowledge of the various attractions and then can decide which route is the most attractive. Some will want to see the Grand Canyon of the Arizona, a sight worth a trip across the country. Others will feel more favorable to the Pike's Peak country, Manitou, the Garden of the Gods and the various attractions of that part of the Rocky Mountains. Others will have a great desire to see the Yellowstone Park and its wonders. Still others will seek the northwestern part of the country—Oregon, Washington, etc., and the attractions of the Canadian Rockies on the Canadian Pacific. Not all of these can be seen on one trip, even on the round trip. Each individual should make up his mind what he is most anxious to see and then study the various itineraries and learn which one will best suit him.

The advantages of selecting one of the special trains, rather than to go by the regular trains, are the additional conveniences provided, the pleasure of traveling with friends and acquaintances, and the relief from the cares of looking after change of trains, hunting up conveyances for side trips, guides, etc., and the satisfaction of having everything provided in advance for comfort and for entertainment during the trip.

We mention below the special trains concerning which we have received information:

American Medical Special.—This luxurious Pullman train with full equipment will run from Chicago to Los Angeles via the Santa Fe and will leave Chicago at 8:00 p. m., Wednesday, June 21, reaching Kansas City at 9:00 a. m., Thursday, June 22, and running thence through New Mexico and Arizona to Los Angeles, which will be reached Monday, June 26, at 7:00 a. m. At Albuquerque the train will make a stop of an hour and a half to allow an inspection of the Fred Harvey collection of Indian handwork. Another stop will be made at Laguna, where an hour will be allowed to inspect the village of the Laguna Indians. The train will stop at the Grand Canyon for twenty-eight hours, giving opportunity to see the Grand Canyon of the Arizona. The desert of lower California will be crossed in the night. At San Bernardino the train will be divided—one section running through directly to Los Angeles, arriving at 7:00 a. m.—and the other going via Redlands and Riverside, stopping at each of these places to allow visits to points of interest. This section arrives at Los Angeles at 4:30 p. m., Monday. Special illustrated folders, reservations and full information may be obtained from G. T. Gunnip, General Agent, A. T. & S. F. Ry., 105 Adams Street, Chicago.

American Academy of Medicine Tour.—Another trip arranged from the east is that of the American Academy of Medicine, whose itineraries have been selected and arranged under the guidance of the passenger departments of the railroads to secure the most desirable trains and the best disposition of daylight sight seeing. Regular trains will be used. This party will leave New York over the Lehigh Valley railroad at 11:55 a. m., Monday, June 12, Philadelphia, at 12:30 p. m., and join the New York train at South Bethlehem at 2:12 p. m. and arrive at Buffalo over the Lehigh Valley at 10:27 p. m. The route will be thence over the Grand Trunk to Chicago, the Burlington to Denver and to Los Angeles over the Santa Fe. Interesting side trips and visits to the points of interest in Colorado and to the Grand Canyon will be provided for and Los Angeles will be reached Friday, June 23, in time for the sessions of the academy, which meets in advance of the American Medical Association. This party may be joined at various points along the route at a much later date, in case it is not desired to spend so much time on the going trip. Reservations for this party are to be made through the secretary, Dr. Charles McIntire, 52 North Fourth Street, Easton, Pa., from whom may be obtained the folder containing all details, both of the outgoing and of the return trip.

Burlington-Colorado Scenic Special.—This special train from Chicago to Los Angeles, via the Burlington, Denver & Rio Grande and the Salt Lake Route, will have the finest equipment of the Burlington road. It leaves Chicago at 11:00 p. m., June 21, and reaches Denver at 7:00 a. m., June 23. The party will spend four hours in Denver and vicinity, leaving at 11:00 a. m., June 23, reaching Colorado Springs (Manitou) at 1:30 p. m. The train will be parked and will remain there all night. This will give an opportunity for the party to go up Pike's Peak, visit the Garden of the Gods, Cheyenne Canyon, the celebrated "High Drive," the famous Iron and Soda Springs, and other points. The train leaves Manitou at 4:30 a. m., June 24, and reaches the Royal Gorge at 7:30 a. m., giving a splendid opportunity to see this wonderful gorge. At Glenwood Springs, an hour and a half will be spent, and Salt Lake City will be reached at 8:30 a. m., June 25. Four hours will be spent in Salt Lake, leaving at 1:00 p. m., and Los Angeles will be reached at 12:00 o'clock noon on June 26. This train traverses the mining regions of Utah and Nevada, and Rainbow Canyon and the Canyon of the Mojave River before reaching the orange country of southern California. This train has been arranged at the request of many physicians (represented by Drs. Robert T. Gillmore, Sidney Kuh and Charles B. Reed), who want to go by the Manitou and Royal Gorge route. Full details and illustrated booklets may be obtained from A. J. Poole, General Agent, C. B. & Q. Ry., Chicago.

Chicago Medical Society Special.—The special train of the Chicago Medical Society will leave Chicago at 9:15 p. m., June 22, via the C. & N. W. Ry.; arrive in Omaha 9:15 a. m., June 23, leave Omaha 9:30 a. m., arrive in Salt Lake 1:30 p. m., June 24, spending the afternoon at Salt Lake, leaving at 5:30 p. m., June 24, via Salt Lake Route, arriving at Los Angeles at 4:30 p. m., June 25. This train will be provided with full Pullman equipment of the most complete and modern character. Meals in dining car will be served à la carte. At Salt Lake arrangements will be made for a special organ recital at the Mormon tabernacle, balance of the afternoon to be spent in sight-seeing. Leaving Salt Lake, the journey lies over the Salt Lake Route through Utah and Nevada, reaching the rich mining districts, passing through Caliente, where Rainbow Canyon is entered, with its great walls of rock of every shade; and Las Vegas. Entering California, the line traverses the canyon of the Mojave river and at San Bernardino reaches the famous Orange Belt of California. The train then runs through Riverside, Ontario and Pomona, cities situated in the fruit-growing section adjacent to Los Angeles. Arrangements have been made so that any physician anticipating telegrams en route will have same sent in care of this special train and be received promptly. Standard sleeping car rate, $13.00 for double lower berth, $10.40 for upper berth, $36.50 for compartment, and $46.00 for drawing room. Elaborate itinerary will be furnished on application to Dr. George F. Suker, Secretary, 103 State Street, Chicago.

Gates Special Train.—A special itinerary is being arranged by the Gates Tours of Toledo, O., with several optional return schedules. A special train will leave Chicago, June 20, stopping enroute at the Grand Canyon, and returning, trains will leave Los Angeles July 1. Full details of the trips, including the return schedules which include Alaska, may be obtained of the Gates Tours, Toledo, O.

Missouri Valley Special.—This special train, under the auspices of the Medical Society of the Missouri Valley and the Medical Association of the Southwest, will accommodate members from the central west and southwest. It will leave Kansas City Thursday, June 22, via the Santa Fe, and will also stop over one day for the trip to the beautiful Grand Canyon. It will arrive at Los Angeles on Sunday, after the trip through the orange country. The tour will be personally conducted and a special interesting itinerary is planned for the return trip. Full particulars may be obtained, and hotel and Pullman accommodations arranged for, through Dr. Charles Wood Fassett, St. Joseph, Mo.

New York and New England Special.—This is another train which has been planned in care of McCann's Tours by Dr. Wisner R. Townsend, Secretary of the New York State Medical Society. This train, fully equipped with modern conveniences and comforts, will leave New York, via the New York Central Lines, at 6:30 p. m., Monday, June 19, connecting with trains leaving Boston at 2:00 p. m., Worcester at 3:11 p. m., Springfield 4:40 p. m., and Pittsfield 6:30 p. m. It leaves Albany at 9:55 p. m., Utica 11:55 p. m., Syracuse 1:08 a. m., June 20, Rochester 2:45 a. m., Buffalo 4:30 a. m. The train will run thence via Cleveland, Indianapolis and St. Louis, and from Kansas City via the Santa Fe through New Mexico and Arizona, reaching the Grand Canyon, Friday, June 23, where twenty-eight hours will be devoted to sight seeing in this marvelous natural chasm, one of the wonders of the world. Los Angeles will be reached at 9:00 p. m., June 25. Time will be allowed to visit the famous orange groves and to view the other points of interest at Riverside and Redlands, as has been described above concerning the other trains. The return trip is one of some length and will include many other parts of the beautiful west which are to be enjoyed at leisure. Information concerning this tour and the daily schedule of the train, including the various possibilities on the return trip, may be obtained through Dr. Wisner R. Townsend, 125 W. 58th Street, New York City.

Pennsylvania Special.—From the east a personally conducted tour has been arranged under the direction of Dr. C. L. Stevens, Secretary of the Pennsylvania State Medical Society, Athens, Pa., in conjunction with McCann's Tours. The train will be of the highest grade Pullman equipment, including a gentlemen's club car and a ladies' club and observation car, with all the accessories and accommodations of the modern train *de luxe*. The special train will leave Jersey City Saturday, June 17, at 4:14 p. m., via the Lehigh Valley railroad, and may be joined at various points between there and Buffalo by passengers from New Jersey, eastern Pennsylvania and Maryland. The train will leave Buffalo via the Lake Shore at 4:30 a. m., June 18, running thence through Cleveland, Indianapolis, St. Louis, Kansas City, Santa Fe, and Albuquerque to the Grand Canyon, where a side trip of twenty-eight hours will be made. Thence the route will include the heart of the orange country in California, Riverside and Redlands, at both of which places time stops will be made. Los Angeles will be reached Friday, June 23, at 9:00 p. m. Full information concerning this tour is contained in a little booklet, which may be obtained from Secretary Stevens.

RETURN TRIPS

As will be noted, several of these tours provide for the return trip by different routes, with interesting side trips. Full information about them can be obtained from the railroads or from the parties named above. In the advertising pages of The Journal, now and in later issues, will be found announcements of many of these railroads and trips. Members are urged to secure the booklets and folders issued by the railroads concerning these trips and post themselves in order to secure the greatest advantages from the visit to the west.

There are numerous ways of returning from the meeting, all of which offer advantages that will appeal to the members and their friends. The return trip from Los Angeles may be made by boat to San Francisco, Portland and Seattle, or by the southern routes over the Southern Pacific, the Rock Island, the Santa Fe, the Salt Lake route or through San Francisco by way of the Southern Pacific and Union Pacific, which offers opportunity for a side trip to the Yellowstone Park and a visit to Salt Lake and all the points of interest in Colorado. Or the return trip may be made by the northern routes—the Northern Pacific, the Chicago, Milwaukee and St. Paul, the Great Northern or the Canadian Pacific—visiting the cities of the northwest—Portland, Tacoma, Seattle and Vancouver—and the various points of interest in the Rockies, including the trip to Yellowstone Park, which may be reached from the Northern Pacific at Livingston, Montana.

Even Alaska and Hawaii will be visited by some. The beauties of the west are at the service of the physicians and their families and friends, and a delightful outing is ready.

Marriages

LEROY S. TOWNSEND, M.D., to Mrs. Grace R. Coates, both of Beaver Falls, Pa., February 28.

GEORGE A. NOLAND, M.D., Ashburn, Va., to Miss Mary Louise Lambert, at Baltimore, March 8.

WILLIAM DAVIS TEWKSBURY, M.D., Washington, D. C., to Miss Susan Tidball West, at Roanoke, Va., February 25.

Deaths

William Warren Potter, M.D. A surgeon of skill and judgment, and a student of acumen and originality in medical science, died at his home in Buffalo, March 14, aged 72. He was born in Strykersville, N. Y., and was graduated from the Medical Department of the University of Buffalo in 1859. He came of a long direct and collateral line of celebrated physicians. At the outbreak of the Civil War, he entered the service as assistant surgeon of the Forty-Ninth New York Volunteer Infantry, served in the Army of the Potomac, was captured, and confined in Libby Prison, but soon exchanged. He was afterward promoted to surgeon of the Fifty-Seventh New York Volunteer Infantry, and after the battle of Gettysburg, was assigned to the charge of the First Division Hospital, Second Army Corps. He was brevetted lieutenant colonel, U. S. V. for faithful and meritorious services. After the close of the war Dr. Potter practiced in Batavia but soon returned to Buffalo. Of late years he has limited his practice to gynecology. His society membership includes the American Medical Association, in which he was chairman of the Section on Diseases of Women in 1890; the Medical Society of the State of New York, of which he was president in 1891; the Medical Society of the County of Erie, of which he was president in 1893; and the Buffalo Medical and Surgical Association, of which he was president in 1886. He has been secretary of the American Association of Obstetricians and Gynecologists since 1888; and was president of the Section on Gynecology and Abdominal Surgery of the first Pan-American Medical Congress. Since 1891, he had been the president and examiner in obstetrics and gynecology of the New York State Board of Medical Examiners, and from 1895 to 1899, he was president of the National Confederation of Medical Examining and Licensing Boards. He was also consulting surgeon to the Buffalo General Hospital. Dr. Potter has been editor of the *Buffalo Medical Journal* since 1888. His death is a great loss to his colleagues in Buffalo and western New York and to the medical profession at large.

George Gorgas Craig, M.D. Jefferson Medical College, 1869; one of the most prominent practitioners of western Illinois, died at his home in Rock Island, March 12, from pneumonia, complicated by cirrhosis of the liver, aged 65. At the age of 17 he enlisted in the Fifty-First Pennsylvania Volunteer Infantry and served through the last two years of the Civil War. Immediately after his graduation he moved to Rock Island, where he afterward resided. In May, 1889, he was appointed acting assistant surgeon U. S. Army and surgeon to the Rock Island Arsenal by the Secretary of War and served continuously in this position until his death. When the Medical Reserve Corps was created he was commissioned as a first lieutenant in that body. Dr. Craig devoted much time to the study of sanitary science and was instrumental in the organization of the Health Department of Rock Island. In 1896, with Dr. Carl Bernhardi, and the late Dr. C. C. Carter, he founded the Rock Island Sanitarium, with which he was connected until it was dissolved in 1906. His society membership included the American Medical Association, American Public Health Association, and Association of Military Surgeons of the United States. He was past president of the Illinois and Iowa Central District Medical Association, and Rock Island County Medical Society.

Warren Bell Outten, M.D. Washington University, St. Louis, 1866; a member of the American Medical Association; and a prominent railway surgeon of the Southwest; died at his home in St. Louis, March 18, from pneumonia, aged 66. For thirty-six years Dr. Outten was chief surgeon of the Missouri Pacific Railway Hospital Department. He was consulting surgeon to the Missouri Pacific System, and president of the National Association of Railway Surgeons. During the cholera epidemic in 1866, he served as acting assistant surgeon U. S. Army. He was consulting surgeon to the St. Louis City Hospital, St. Luke's Hospital, the Baptist Sanitarium, and Mount St. Rosa Infirmary. He was also president of the *Interstate Medical Journal* Company. Dr. Outten was an authority on railway injuries, and was the author of a valuable work entitled "Railway Injuries; Their Clinical and Medicolegal Features."

Pierre Wilson, M.D. Missouri Medical College, St. Louis, 1884; formerly a member of the American Medical Association; professor of pathology, gynecology and abdominal surgery in Baylor University. Dallas, Tex.; died at his home in Harlingen, Tex., March 8. The Dallas Medical and Surgical Society, at its monthly meeting, March 10, adopted resolutions setting forth the service to humanity rendered by Dr. Wilson, and extending sympathy to his family. Similar resolutions were passed by the students of the departments of medicine and pharmacy of Baylor University.

Samuel Hall, M.D. New York University, New York City, 1843; a member of the Volunteer Corps of New York City during the Civil War; formerly a member of the New York Academy of Medicine, and vice-president of the Medical Alumni Association of New York University; consulting physician to the Northern Dispensary, commissioner of public works in New York City in 1873; and trustee of the New York and Brooklyn Bridge; president of the school board of Rye in 1894; died in his apartments in New York City, March 10, aged 91.

Thomas F. O'Malley, M.D. Rush Medical College, 1886; a member of the Illinois State Medical Society; who in his young manhood studied for the priesthood in Ireland but was never ordained; from 1892 to 1899 chief medical examiner of the Catholic Order of Foresters; died at his home in Chicago, March 19, from pneumonia, aged 50.

Horace A. Peabody, M.D. College of Physicians and Surgeons, Chicago, 1886; formerly a member of the South Dakota State Medical Association; a specialist on diseases of the eye, ear, nose and throat of Webster; formerly president of the State Board of Health; died in St. Augustine, Fla., March 6, from heart disease, aged 55.

John A. M. Lambert, M.D. Medical School of Maine, Brunswick, 1852; formerly president of the Bennington County (Vt.), and Berkshire County (N. Y.) Medical Societies; historian of Washington County (N. Y.) Medical Society; died at his home in Salem, N. Y., March 2, from cerebral hemorrhage, aged 82.

Hiram Noble, M.D. Victoria College, Coburg, Ont., 1857; formerly of Onawa, Iowa; and later councilman and twice mayor of Blair, Neb.; a member of the Washington County board and of the local pension board, and county physician; died at his home in Blair, March 8, from cerebral hemorrhage, aged 82.

Thomas Beattie, M.D. University of Edinburgh, Scotland, 1849; M.R.C.S., Edinburgh, 1849; surgeon of the ship *Restitution* on its cruise round Greenland in 1849; for more than fifty years a practitioner of Cass County, Mo.; died at his home in Harrisonville, February 3, from cerebral hemorrhage, aged 83.

Harry Cheetham Leech, M.D. University of Pennsylvania, Philadelphia, 1907; of Providence, R. I.; died in a drugstore in that city, March 6, aged 26, from the effects of a gunshot wound of the head, self-inflicted, it is believed, with suicidal intent, while despondent on account of the death of his mother.

Thomas L. Foulds, M.D. Indiana Medical College, Indianapolis, 1876; a member of the American Medical Association; formerly president of the Alton (Ill.) Medical Society; a specialist in diseases of the eye, ear, nose and throat; died at his home, March 7, from kidney disease, aged 57.

James Dow Appley, M.D. Philadelphia College of Medicine and Surgery, 1871; a member of the American Medical Association; local surgeon for the Delaware and Hudson Railroad; died at his home in Binghamton, N. Y., February 18, from valvular heart disease, aged 65.

Clara A. Swain, M.D. Woman's Medical College of Pennsylvania, Philadelphia, 1869; for forty years a missionary in India, where she was a pioneer in the establishment of hospitals for women; died at her home in Brookside, Castile, N. Y., Dec. 25, 1910, aged 76.

Marion Augustus Baldwin, M.D. Tulane University, New Orleans, 1866; local surgeon at Cuthbert, Ga., for the Central Railroad of Georgia, and a member of the National Association of Railway Surgeons; died at his home, March 2, aged 78.

William B. Young, M.D. Medical College of the State of South Carolina, Charleston, 1904; of Rockhill; a member of the South Carolina Medical Association; died in the Florence (S. C.) Infirmary, Dec. 20, 1910, from typhoid fever, aged 33.

"The Propaganda for Reform".

In This Department Appear Reports of the Council on Pharmacy and Chemistry and of the Association Laboratory, Together with Other Matter Tending to Aid Intelligent Prescribing and to Oppose Medical Fraud on the Public and on the Profession.

PROPRIETARY VERSUS UNPROTECTED NAMES

The Question of Term to be Applied to the Active Principle of the Suprarenal Gland

Some years ago the Council on Pharmacy and Chemistry decided that it was necessary to adopt, in each instance, a generic term to designate those products that are on the market under two or more proprietary names. When it came to the consideration of the various preparations of the blood-pressure-raising principle of the suprarenal gland which were on the market, it was necessary to establish some name that should be common to all of them. The name adopted was "epinephrin." This was selected in part because it was the name under which the preparation was first called to the attention of the profession of this country by Professor Abel, as will be mentioned later. Further, the name is one which is as appropriate for the preparation as any adopted by the various manufacturers, and is, in addition, easily learned. We doubt if any one will deny that the Council on Pharmacy and Chemistry, representing as it does the American Medical Association and the medical profession of the United States, has as much right to adopt a name for the preparation as has any manufacturing firm.

For several years The Journal has endeavored to follow the unquestionably correct plan of using the scientific name of a drug or medicinal preparation in preference to the coined trade name—the proprietary name given by the manufacturer. After the adoption of the term "epinephrin," The Journal began occasionally to substitute that term for the proprietary names of suprarenal products in abstracting, but only in instances in which it was evident that the author was using the proprietary name in a general sense. In original articles, however, this was not done without the author's permission. In this way it was hoped that the medical profession would gradually be led to appreciate the fact that there is a common name for the substance. Only one protest has been received, and that from Parke, Davis & Co., a firm which sells the substance under the name "adrenalin." It was as follows:

PARKE, DAVIS & CO. PROTEST

To the Editor:—We wish to protest against the unfair manner in which one of your department editors (Current Medical Literature) is treating us.

When a reputable practitioner reports to the London *Lancet* that "the effects from the treatment of the paroxysms of asthma by the hypodermic injection of adrenalin are marvelous," your department editor is taking an unjustifiable liberty when he changes the word adrenalin to epinephrin. He knows, you know, that there is no such thing on the market as epinephrin, and that Dr. Melland used our product, adrenalin; that over 90 per cent. of all clinical work done with the active principle of the suprarenal gland is done with our preparation, adrenalin, and that it is equally unfair to your readers and unfair to the manufacturer to deliberately substitute any other name—just as wrong as it would be for a druggist to substitute any other product.

In the *Wiener klinische Wochenschrift*, May 12, Dr. Kreibich did not treat of the subject which you put in his mouth. His article was devoted to "Adrenalin Technic for Determination of Leukocytes in Tissues." Do you think it right to put in his mouth a name of which Dr. Kreibich probably never heard in his life?

It is no answer to say that you have given the same treatment to one of our competitors in abstracting an article from the *Deutsche Zeitschrift für Chirurgie*. Dr. Heidenhain undoubtedly never heard of epinephrin. He writes of the behavior of a preparation made by one of our competitors, suprarenin.

We spent tens of thousands of dollars on experimental work before our chemist, Dr. Takamine, isolated the active principle of the suprarenal gland. We now pay him a royalty on every grain of the drug and every ounce of the solution. You know that there is no such thing on any market as epinephrin. And yet you try to deprive us of the credit which is fairly ours. A fine premium you are putting on originality, enterprise and research work by commercial houses! Here we have enriched the practice of medicine with the most remarkable agent discovered since Köhler noted the anesthetic properties of cocain (excepting always the antidiphtheritic serum); yet when a reputable physician reports his experience to the medical press, The Journal of the American Medical Association deliberately strikes out the name used by the author and substitutes one of its own.

Is this the way to teach ethics to others?

Parke, Davis & Co.,
E. G. Swift, General Manager.

This letter was received last June. Immediately after its receipt we began an investigation as to the views of those who use the name "adrenalin" in their printed articles. To this investigation we shall refer again. It is mentioned here to explain why the letter has not been published before.

SCIENTIFIC NAMES A NECESSITY

Aside from the question of priority of discovery, this protest raises a problem much broader and deeper than any question of personal credit or commercial aggrandizement, one which concerns the ethical and scientific status of protected names. In all countries the use of trade names in scientific treatises is discountenanced, and for very evident reasons. Hence a medicinal substance should have a scientific name by which it may be known in literature in contra-distinction to any trade name by which it may be called. This is especially true when a substance is sold under two or more proprietary names.

There are already thirty or forty different trade names for this active principle.[1] There is nothing to prevent a hundred firms or individuals from marketing this substance, each under a different trade name. Can nothing then be done? Are our abstracters to quote each of these one hundred or more names? Is it necessary that a physician use some trade name every time he mentions the substance?

If there were but one product on the market, there might be comparatively little objection to the use of the proprietary name as a generic term. When there are several, however, the adoption of one proprietary name as a generic term for that whole class of products is an injustice to all the other products in that class. Moreover, in the inevitable confusion that results, science is sacrificed to commercialism.

WHAT A BRITISH EDITOR THINKS

Very recently this same point has been discussed in British medical and pharmaceutical circles. In the London *Lancet*, Jan. 7, 1911, p. 73, there was a short note taking the editor of the "Year Book of Pharmacy" to task for substituting a generic term[2] for the proprietary name "adrenalin" in giving an abstract of an article that had appeared in the *Lancet*. Mr. J. O. Braithwaite, the editor of the "Year Book of Pharmacy," in a letter in the *Lancet*, Jan. 28, 1911, p. 264, justifies his course in using a generic term[2] in such cases, on the reasonable ground that it tends "to lessen confusion and to increase accuracy."

After showing how the use of a multitude of names for the same substance tends to degrade scientific work, Mr. Braithwaite stated that to use, in abstracting, a generic word as a "common denominator," did injustice to no one. Rather, says he: "The injustice, if any, arises entirely from the loose manner in which trade names and proprietary euphemisms are applied to these newer remedies. This has caused them as a class to fall into disrepute, and has reflected hardly on the few more valuable therapeutic articles among them . . . Moreover, it is no function of the 'Year Book of Pharmacy,' in its abstracts to advertise either 'preparations' or persons. These abstracts are intended solely to record scientific facts or practical details of use to pharmacists in their calling, or to those who are interested in the subjects with which they deal."

GENERIC TERMS INJURE NO ONE

The introduction of a generic term does not prevent any physician from using the word "adrenalin," or the proprietary name of any other product. If a physician believes a certain brand to be superior, or if he wishes to contribute royalty to the enterprise of the manufacturer, then he is justified in using the proprietary term.

---

[1] Among the proprietary preparations of the suprarenal principle made in the United States are the following: Adnephrin (Frederick Stearns & Co.), Adrenalin (Parke, Davis & Co.), Adrin (H. K. Mulford & Co.), Supracapsulin (Cudahy Co.), and Suprarenalin (Armour & Co.). In Europe among others are: Atrabilin, Chelafrinum, Epirenan, Hemostasin, Hemisine, Ischemin, Paranephrin (Merck), Renoform, Supranephran, Suprarenaden, Suprarenin (Hoechst), Suprarenin synthetic, Tonogen and Vasoconstrictin.

[2] The generic term used by the editor of the "Year Book of Pharmacy" is "adrenine."

As a matter of fact, the word "adrenalin" has come into use as a generic name because Parke, Davis & Co. were the first manufacturers to "push" this product. This was done in all countries. The name this firm adopted was a catchy one, and as a result it is a fact that to-day, not only in this country but in Europe, "adrenalin" is regarded as a common name by a host of physicians, and used as such. In our correspondence regarding this matter this statement has been made repeatedly: "I used the term 'adrenalin' because I thought it was the common term."

In this connection, we desire to say that Parke, Davis & Co. are mistaken in asserting that we know that Dr. Melland used their preparation. On the contrary, study of his article shows that he used the word in a generic sense. Whether he used the preparation made by Parke, Davis & Co. or some other preparation is not specified.

"Do you think it is right," ask Parke, Davis & Co., "to put into his mouth a name of which Dr. Kreibich never heard in his life?" We think it right to use the word which will convey the idea to the reader's mind without chance of misapprehension. We think it wrong to use a word which has a double sense, when that can be avoided. Unless an author's words are meant to apply solely to the preparation made by Parke, Davis & Co., it is not right that that product should derive benefit from them.

Say Parke, Davis & Co.: "You know that there is no such thing on any market as epinephrin." This is true, and for the simple reason that every manufacturer, for purely commercial reasons, without regard to science, adopts a trade name for his product and pushes that product under that trade name for all it is worth. But if medical men will make it a point to use the word epinephrin in their discussions, in their writings, and in their prescriptions, it will not be long before there will be plenty of epinephrin on the market. As a matter of fact, already one firm (Mulford & Co.) has used as a synonym for its preparation, adrin, the term "epinephrin" and two other firms have expressed willingness to adopt epinephrin as a synonym. We sincerely hope that in the interest of science other manufacturers will do likewise, although it may be too much to expect that all will take this enlightened attitude.

COMMERCIAL PREPARATIONS NOT IDENTICAL

It is understood, of course, that the preparations on the market are not necessarily identical, since the drug is in solution, and these solutions vary according to the preservative and the solvent used.[3] On this account some physicians will find it more satisfactory to use this or that firm's product, in which case they would *of course indicate* it either by appending the firm's name after the common term "epinephrin," or by using the firm's trade name.

In view of the fact that the name "adrenalin" has been trademarked by the manufacturers of this particular product and is, therefore, no longer the scientific name for the suprarenal principle, the question of priority in its discovery or preparation is one of minor importance in this connection. However, the history of this drug disproves the claim of the manufacturers of "adrenalin" of exclusive priority in the discovery. The progress of scientific discovery is rarely such that any firm or individual can truly claim all the credit.

But before going into the history let us again quote from the Parke-Davis letter:

> We spent tens of thousands of dollars on experimental work before our chemist, Dr. Takamine, isolated the active principle of the suprarenal gland. We now pay him a royalty on every grain of the drug and every ounce of the solution. You know that there is no such thing on any market as epinephrin. And yet you try to deprive us of the credit which is fairly ours. A fine premium you are putting on originality, enterprise and research *work by* commercial houses! Here we have enriched the practice of medicine with the most remarkable agent discovered since Köhler noted the anesthetic properties of cocain (excepting always the antidiphtheritic serum); yet when a reputable *physician* reports his experience to the medical press, THE JOURNAL of the American Medical Association deliberately strikes out the name used by the author and substitutes one of its own. Is this the way to teach ethics to others?

How much Parke, Davis & Co. spent on the experimental work that resulted in Takamine isolating "adrenalin" is a matter best known to that firm. The following quotation from the article[4] by Takamine in which he announced the results of his work is interesting in this connection:

> "Having been interested in this subject for some time *I recently commenced* to make research along that line. I am now pleased to announce that *I have succeeded in isolating the blood-pressure-raising principle* of the gland in a stable and pure crystalline form." [Italics ours.—ED.]

If Takamine isolated "adrenalin" so soon after commencing his research work, one wonders why it was necessary for Parke, Davis & Co. to expend "tens of thousands of dollars" for such a rapid piece of work. But this point is immaterial. The implication here is that Parke, Davis & Co. deserve the sole credit for the discovery of the active principle of the suprarenal glands. Now for the facts regarding this matter.

THE HISTORY OF THE DISCOVERY

More than half a century ago it was discovered that the suprarenal glands contain substances which give peculiar color reactions.[5] These properties were believed to be due to the presence of pyrocatechin or to its derivatives. Since 1894[6] it has been known that extract of the suprarenal glands possessed remarkable blood-pressure-raising and local astringent properties.

The blood-pressure-raising principle of the suprarenal gland was first isolated by Abel and Crawford[7] in 1897 in the form of its benzoyl compound. Finding this substance and its derivatives to be physiologically active, Abel believed that he had isolated the true active principle of the suprarenal gland in a pure state and named it "epinephrin,"[8] meaning, of course, that the name should apply to the true blood-pressure-raising constituent. The soluble salts of epinephrin, as prepared by Abel would, no doubt, have met all the needs of practical medicine if his methods of preparation had not been too expensive.[9]

Contemporaneous with Abel's earlier researches, v. Fürth[10] succeeded in isolating from the glands in an impure state an active principle which he called "suprarenin." In 1901, four years after Abel's first report, Takamine,[11] separated an active principle from the glands which he called "adrenalin." In the same year, Aldrich,[12] a former associate of Abel, independently produced an active principle, *said to be much purer than* Takamine's, which he also called "adrenalin." That Aldrich's product was purer than Takamine's is shown by a comparison of the formulas given by the respective authors. Takamine originally stated that the formula for his adrenalin was $C_{10}H_{15}O_3N$, while Aldrich (from the analysis of his own product) assigned the formula $C_9H_{13}O_3N$. Aldrich's formula has since been confirmed by many independent investigators, while no one has ever been able to substantiate the formula originally claimed by Takamine. This fact alone demonstrates that Takamine can have no legitimate claim to be the first to isolate the active substance in a pure state.

It is evident that all these investigators were working with the same substance, in varying degrees of purity. In fact, with the exception of mentioning v. Fürth's name, this is the belief of Crawford,[12] Abel's early associate. This opinion, however, was written by Crawford, a decade after his work with

---

[3] There is on the market a synthetic product called L-suprarenin synthetic bitartrate. See THE JOURNAL A. M. A., Jan. 14, 1911, p. 120. Also N. N. R., 1911, p. 82.

[10] v. Fürth: Ztschr. f. phys. Chem., 1898, xxiv, 142; 1898-9, xxvi, 15.

[11] Takamine: Am. Jour. Pharm., 1901, lxxiii, 523.

[12] Aldrich: Am. Jour. Physiol., 1901, v, 457. The work of Aldrich was published in the same year, but after that of Takamine. He used the name adrenalin also. The statement that Aldrich's product was purer comes from Crawford, now Professor of Pharmacology in Leland Stanford Junior University, California, *formerly* with Parke, Davis & Co. This statement was published by Crawford in the Bulletin of the Bureau of Plant Industry, No. 112, 1907, p. 16.

[13] Crawford: U. S. Dept. of Agric., Bur. Plant, Ind., Bull., cxii, 10.

Abel. Jowett, in England, several years earlier had come to the same conclusion.[14] He says: "'Epinephrin,' 'suprarenin' and 'adrenalin' refer to the same substance." Concerning the proper name for the active substance of the suprarenals, this chemist says: "As this author (Abel) was the first to isolate the substance. although *in an impure condition*, it would seem that the name originally assigned by Abel, to the active principle, should be the one adopted."

A review of the facts as briefly stated above shows that Abel's reports as well of those of v. Fürth were published in 1897-99. long before Takamine's announcement of the isolation of "adrenalin." To Abel, then, more than to any other, belongs the credit of having paved the way for the perfection of epinephrin. As we stated before, therefore, the name which he selected for the substance is the scientific one, the only proper one, if for no other reason than on account of the priority of his systematic researches. We contend, therefore, that "epinephrin" is the most correct generic name for the suprarenal principle and that the Council on Pharmacy and Chemistry did well in selecting this term.

SOME OPINIONS

To ascertain whether authors in speaking of "adrenalin," always mean the Parke Davis preparation, or whether they generally intend a wide application, we entered into correspondence with those who mentioned the word "adrenalin" in their articles, and we quote from some of the replies (italics ours):

Dr. Edward B. Bigelow, Worcester, Mass., says:

> Personally, I do not intend to use trade names or write prescriptions for proprietary preparations, although, occasionally, I must admit that I do the latter. *As a matter of fact, through ignorance, I used the word "adrenalin," considering it to be the general term for the preparation* and not knowing, until you called my attention to it, that epinephrin is that term. On looking the matter up, the preparation really used by me was "supracapsulin." I shall be pleased to substitute the word "epinephrin" where I used the word "adrenalin."

Dr. E. Fletcher Ingals, Chicago, in discussing a paper in the Section on Laryngology and Otology last June, spoke of using adrenalin. In reply to our letter he says:

> *I used the term in a general way*, for I seldom use adrenalin as it is too irritating in consequence of chloretone, but use suprarenalin. . . . Your plan is absolutely right and I hope the profession will see it in this way. I shall probably continue to use Armour's preparation, suprarenalin, as I like it best, but we will call it epinephrin.

Dr. Rudolph Matas, New Orleans, says:

> In using the term "adrenalin" I was familiar with the fact that there are several preparations of the same kind under different proprietary names; but, remembering the early work of P. D. & Co. in developing adrenalin among other cruder products of the suprarenal gland, I have clung to them faithfully up to the present time. However, in applying the term "adrenalin," as I have done, especially in our work on local anesthesia, *it was not my intention to specify any particular "makes" of suprarenal product* in preference to any other, but *I meant to use it in a generic sense* without meaning particularly P. D. & Co. in preference to Mulford, Armour & Co., Stearns, etc. I did not have in mind the trade name, but a generic name that applied to the product of the adrenal, which we all recognize as the same thing under various trade names. I see clearly the point you make and believe it is well taken. I am fully in accord with the purpose and the principle upheld by the Council on Pharmacy in doing away with trade names, if possible, but those of us who have been in the habit for years of designating certain things by certain names which are familiar to us find it difficult to break into a new practice.

Dr. John O. Roe. Rochester, N. Y., replied:

> As stated in my article, *it was adrenalin I used in the cases I reported.* I have no objection to the use of the general or generic term covering all the different preparations of this agent, although I stated that I used adrenalin for the reason that I have found it the most active and the most reliable of all these preparations.

Dr. Leo Loeb. St. Louis, says:

> I have no objection to the change you propose in my paper. *I am glad to use the term "epinephrin" instead of "adrenalin."* I am in hearty sympathy with the work done by the Council on Pharmacy and Chemistry.

Dr. A. L. Scharber, Nashville, Tenn., says:

> I did not intend to use any trade name; *I only used it in a general way.* I thought at the time that I had applied the name as it should be. Now, if I had known in time, I should have substituted the word "epinephrin" for "adrenalin."

Dr. Theodore C. Janeway, New York, writes:

> I am heartily in sympathy with your desire to eliminate trade names. *In this case it was P. D. & Co.s preparation.* . . . It seems to me unfortunate that adrenalin, which is used fairly generally in the German literature, should not have the same non-specific signification here, but suppose we cannot help that. Epinephrin always seemed to me a much clumsier name than adrenalin. However, I suppose P. D. & Co. have made it impossible to use the latter.

As stated by Dr. Janeway, "adrenalin" is used as a general term in a general sense in Germany, and in fact all over Europe, as it is in this country, and for the same reason. Thus, to quote only recent literature. Ascher and Flack (*Ztschr. f. Biol.*, 1910, Vol. 55) use the word "adrenalin" throughout their article, in the protocols and conclusions; but on page 115 they state that they actually employed the preparation "hæmostasin." Hirayama (*Ztschr. f. exper. Path. u. Ther.*, 1911, Vol. 8, p. 651) speaks of "adrenalin experiments," but actually used "suprarenin Hoechst" in all cases. This illustrates the generic use of the term. But while the substance is on the market in Europe under a greater variety of names than it is in this country, adrenalin has the same narrow, limited meaning as it does here. Parke, Davis & Co. emphasize this even in their advertisements. In a full page advertisement in the London *Lancet* recently the British profession is advised that "there is only one adrenalin. . . . Parke, Davis & Co. introduced adrenalin into medicine. This principle was isolated in 1900 by Dr. Takamine, a member of their scientific staff, and the sole right of manufacture by his process is vested in them." German physicians are laboring under the same difficulty as physicians in this country would be laboring under were it not for the Council on Pharmacy and Chemistry.

We believe that the patent on adrenalin will expire in five or six years. Then not only the method of manufacturing it but the product itself will be free. But Parke, Davis & Co. will still control the name "adrenalin," and every time the physician prescribes under this term the druggist must use Parke, Davis & Company's preparation.

In scientific literature, however, or whenever the observations or conclusions are not restricted to the Parke, Davis & Co. product, the name "epinephrin" is not only justified, but commendable. The very condition of scientific progress is freedom. The interest of the public and of science demands that this freedom should be maintained. We doubt greatly whether many scientists of established reputation will subscribe to the insinuation in the protest quoted above, that the cause of science is best advanced by restricting its liberty, in order to put a premium on the "originality, enterprise and research work of commercial houses."

Such an attitude would certainly be contrary to the best traditions of medical science. Modern conditions may have necessitated some changes in the traditional practice—but not to the extent that thinking men will agree with the accusation that those who prefer a free name to a "protected" name, are guilty of sophistication and of debauching the ethics of the profession.

PARKE, DAVIS & CO.'S "REPLY" TO THE ABOVE WITH OUR COMMENTS

With a desire to be absolutely fair and to avoid any possible misstatements of facts, a proof of the above was submitted to Parke, Davis & Co. This firm has made a rather lengthy "reply," which ignores the main point—the absolute necessity, in the interest of science, of a practical, generic name—but deals expansively with side issues, especially in extolling their own product. The reply absolutely ignores the point at issue. As will be noticed by those who read the "reply" through consecutively, it contains many reiterations. A slight rearrangement of the paragraphs has been made, therefore, in order that we may comment in one place on related matters. As the paragraphs are numbered, it will be easy for those who desire to do so to read Parke, Davis & Co's "reply" in the order in which it was sent in by them. Omitting the first paragraph, we have arranged the text of the reply under four heads. Their "reply" begins as follows:

---

[14] Jowett: Jour. Chem. Soc., 1904, lxxxv, 192.

To the Editor:—On the following points in the article which you send us, "Proprietary versus Unprotected Names," you take a position which is utterly untenable:

1. Not a single grain of the active principle of the suprarenal gland was on the market, in pure state or in solution, until Parke, Davis & Co. first offered the pure adrenalin and the solution adrenalin chlorid to the medical profession and the drug trade. That we were the first to offer these products for sale has never been disputed.

Comment:—Technically this is true. Nevertheless, under the name "epinephrin," an active principle of the suprarenal gland, as prepared by Abel, was in the hands of clinicians, in the form of a salt and in solution, and was being made the subject of experiment and report to medical societies nearly two years before Parke, Davis & Co. offered it for sale.

I. VARIATIONS IN COMMERCIAL BRAND

2. If you will turn to Bulletin 61 of the Bureau of Public Health and Marine-Hospital Service at Washington, you will find on page 25 a summary of an investigation of six preparations on the market purporting to contain the active principle of the suprarenal gland. In point of activity four of them range from 3.7 to 66.6 per cent. of the normal standard. Only two are pronounced satisfactory (100 per cent.). If you purpose to encourage the use of the generic name for the six preparations, and if a physician prescribe epinephrin, which of the six products would you have dispensed on his prescription—the active, the standardized or the virtually inert? Would you leave the decision wholly to the dispenser? Would you give the physician any voice in the selection of the product that he can trust? And if in your dislike of "trade names" you persist in closing your columns to them and in substituting epinephrin therefor, will you, in justice to the physician and in justice to the particular product which may have been used by your contributor, take the trouble to insert "epinephrin (Jones)," or "epinephrin (Smith)," or "epinephrin (Parke, Davis & Co.)?"

Comment:—This matter has been dealt with (page 911, col. 1, par. 5), in part, as follows: "It is understood, of course, that the preparations on the market are not necessarily identical, since the drug is in solution, and these solutions vary according to the preservative and the solvent used. On this account some physicians will find it more satisfactory to use this or that firm's product, in which case they would, of course, indicate it either by appending the firm's name after the common term 'epinephrin' or by using the firm's trade name."

The introduction of a generic term does not prevent any physician from using the word 'adrenalin' or the proprietary name of any other product. If a physician believes a certain brand to be superior, or if he wishes to contribute royalty to the enterprise of the manufacturer, then he is justified in using the proprietary term.

We have no complaint against the use of a trade name when the prescriber, author or abstracter intentionally restricts his remarks to that one particular preparation, as in the comparative investigations quoted in the reply. But as we have pointed out, practically all authors intend to use a generic name, and think that they are doing this.

3. Allow us to remind you of your own words in THE JOURNAL of the American Medical Association, Feb. 26, 1910, page 710:

"Schultz has just published the results of a careful examination of samples of the suprarenal preparations on the American market, which illustrated once more the need of more care in the methods of preparing and keeping this important drug. Of the six different products only two were of the strength claimed; the others vary from 3.7 to 66.6 per cent. of this strength. . . . Hunt in 1906 showed that some of the preparations labeled 1:1,000 had only one-fifth of the activity of others bearing the same label. Sollmann and Brown of Cleveland, Ohio, showed the activity of eight commercial preparations to differ greatly. . . . The fact remains, however, that inferior preparations are on the market and are probably passing into the hands of physicians daily. . . . There are reasons for believing, however, that some of the firms preparing this and some other drugs requiring physiologic standardization are not properly equipped for the work."

If, now, the physician prescribes simply "epinephrin," what ground has he for complaint if a solution containing 3.7 per cent. of proper normal potency is dispensed?

5. Those manufacturers who are making substitutes for adrenalin will rejoice to know that an influential medical journal is supporting their attempts to destroy in the minds of physicians the distinction between their products and the original. No wonder that one or more of them have been willing to accept your suggestion and attach the word "epinephrin" to their labels! Why should they *forego* your help in rectifying their past failures to give standing to their imitations and substitutes?

Comment:—We are not aware that there is any "distinction," other than the variability which may exist between any two commercial brands of the same substance. This variation is unfortunate, and should be speedily abolished by the standardization of *all* the brands—a work which the Council on Pharmacy and Chemistry is trying to accomplish. Instead of this, Parke, Davis & Co. propose to meet the conditions by creating and perpetuating a monopoly.

To realize the absurdity of this, we need only consider a few analogous examples: Common table salt is not absolutely pure. Let us suppose that a commercial firm markets a pure sodium chlorid under a protected trade name. Must scientists henceforth drop the scientific name of "sodium chlorid" or the public the common name "salt," because uniformity would be promoted thereby? Again: Digitalis preparations vary notoriously. Let us suppose that Smith, Jones & Co. invent a more uniform preparation and incidentally also invent a new name. Should the name "digitalis" now be dropped from the literature, because it refers to variable products? Or again, let us now suppose that we now accomplish the impossible and accept "adrenalin" as the generic name; must we change this every time that some one finds a better way of making a somewhat purer product, or a more stable solution? Parke, Davis & Co. bring another argument along the same line:

7. Your own laboratory (THE JOURNAL A. M. A., Oct. 31, 1908, pp. 1524-25), has borne witness that of four samples (of preparations purporting to be solutions of the active principle of the suprarenal gland) *only one* did not contain sodium sulphite or a similar bleaching agent—an agent which is generally conceded to have *no* real preservative effect, and only serves to deceive the physician by masking the tell-tale evidence of decomposition. We do not ask you to publish the name of the manufacturer of the lone sample: we can guess for ourselves.

Comment:—We do not know at all that "it is generally conceded" that the sulphite has no real preservative action and is therefore a fraud; or that the infinitesimal dose used is at all harmful; or that it is in any way inferior to the preservative used in "adrenalin solution." In the absence of any evidence in this direction, the Council had to be content with a statement of the nature of the preservative; but if good evidence is adduced, the Council will doubtlessly apply it.

II. EXPENSE OF DISCOVERY

Parke, Davis & Co. lay great stress on the matter of the expense of discovery in the following paragraphs:

4. The relative merits of Takamine and Aldrich, on which you dwell, have no bearing on the case. Both were in our employ during and before their work on the suprarenal gland. Aldrich entered our service July 10, 1898, and devoted more than two years to this work. Takamine had the good fortune to reach the coveted goal first. With either or both, Parke, Davis & Co. share the credit, for obvious reasons.

6. Much is said of the selfish motives and the pecuniary rewards of the manufacturer, little or nothing about his outlay, his financial hazard, his losses. Few remedies of real value are brought forth in this era save by highly trained and well-paid men working in costly laboratories. The world hears of the success, applauds the discoverer (perhaps), and utilizes the remedy. No one thinks it worth while to ascertain the costly failures, for the failures cost as much as the successes, and the returns from one success must necessarily offset the losses of a half dozen failures.

Comment:—Just when, where and how long Drs. Takamine and Aldrich were in the employ of Parke, Davis & Co.; what were their salaries and other conditions of their employment; what proportion of their time was devoted to investigations of the suprarenal problem; what other use may have been made of them—or in fact, what were the expenses of Parke, Davis & Co. in discovering adrenalin, and the probably vastly larger expenses of advertising it, what is the present rate of profit, etc.—all these are questions which may have an interest of their own; but we fail to see what practical bearing they have on the question whether we need a generic name for the numerous commercial brands of an identical substance; or even on the choice of name, since the Parke, Davis & Co. name is protected, and therefore not available as a generic name.

In passing, however, it may be remarked that so far as the mere question of expense is concerned, Takamine and Aldrich, and through them Parke, Davis & Co., certainly profited somewhat by the work of the preceding and contemporaneous workers in the same field; but we have still to learn that they have made any efforts to reimburse these "outsiders" for their share of the expense. In the aggregate, this was doubtless much greater than that of Parke, Davis & Co. The independent workers were not looking to financial encouragement; they were looking to the benefit of mankind; they are entitled to *that* benefit, and presumably would not accept any other. Parke, Davis & Co., however, would take this benefit from them, capitalize it, and convert it into dividends. These independent investigators doubtless believed, as we have said, that they were working for the benefit of humanity; it appears, however, that they were, in fact, working for the exclusive benefit of Parke, Davis & Co. This is one of the unfair phases of commercialized research.

III. PRIORITY OF DISCOVERY

As we have repeatedly pointed out, the "priority of discovery" has no practical bearing on the need, or in this case even on the choice, of a generic name; for a generic name, by its very definition, cannot be monopolized, and "epinephrin" is the only current name for the substance which has not been monopolized. It was not even proposed for any specific product, for Abel said: "I therefore name the blood-pressure-raising substance (of the suprarenal gland) 'epinephrin,' in accordance with Hyrtl's nomenclature" (*Hoppe-Seyler's Ztschr.*, 1899, xxviii, p. 321).

However, since Parke, Davis & Co., in their first letter, claimed to have "enriched the practice of medicine with the most remarkable agent," etc., we felt it our duty to point out that such a claim deprives Dr. Takamine's predecessors of the large part of the credit which is fairly theirs. The "enrichment" really dates from the discovery, by Oliver and Shäfer, of the vasoconstrictor action of the gland, which led to its therapeutic use. Had it not been for this demonstration of the therapeutic potentialities of the gland, Parke, Davis & Co. would probably not have dreamed of financing its investigation. For this then they deserve no credit. The next step was the demonstration that this action resides in a definite chemical substance; and this substance, in the form of a benzoyl derivative, was first isolated by Abel—also without the aid of Parke, Davis & Co. Had it not been for the demonstration of the basic character of this substance, Dr. Takamine might still be floundering in the dark for a process of isolation.

The next step was the isolation of the natural base, and the credit for this, we say without hesitation, belongs to Takamine, Aldrich and Parke, Davis & Co. This was followed by the determination of the structural formula; and finally by the synthesis of the substance. In the last, Parke, Davis & Co. again had no share. In such a chain of discoveries, is it right for anyone to claim exclusive credit; to imply that he alone has enriched the profession? Is it possible even to say who should have the major share? We do not believe so, and we shall not attempt it. We concede a fair share to Parke, Davis & Co., namely, the final isolation of the natural base. We do not blame them for speaking warmly on this point, nor even for some partiality to their own merits; and therefore we shall comment only on such of their statements as are distinctly unfair to other investigators, hence, subdivisions a to f, inclusive, of paragraph 8 are not commented on, while subdivisions i. j and k are discussed separately.

8. (a) You do us and our employees an injustice in the language which implies that Professor Abel was mainly responsible for the discovery and preparation of the pure, active principle of the suprarenal gland. Abel was not the first to learn that this gland contained some substance giving a peculiar chemical (color) reaction. This was demonstrated by Vulpian (*Compt. rend. Acad. d. Sc.*, Paris, 1856, xliii, 663-665) in 1856 and confirmed by Virchow (*Virchow's Arch. f. path. Anat.*, 1857, xii, 481) in 1857. He was not the first to believe that these glands contained some active principle, because Vulpian and Cloez (*Compt. rend. Acad. d. Sc.*, Paris, 1857, xlv, 340) in 1857, and Arnold (*Virchow's Arch. f. path. Anat.*, 1866, xxxv, 64) in 1866, and Holm (*Jour. Pract. Chem.*, 1867, c, 150) in 1867, had arrived at the same conclusion, as is shown by their attempts to isolate such an active principle.

(b) He was not the first to demonstrate that these glands contained a substance of undoubted chemical similarity to another well-known substance, for Krunkenberg (*Virchow's Arch. f. path. Anat.*, 1885, ci, 542) in 1885 called attention to the similarity between the color reactions of the extract of this gland and those of pyrocatechol. Also, Brunner (*Schweiz. Wchnschr. f. Pharmakol.*, 1892, xxx, 121) in 1892 confirmed Krukenberg's conclusions in reference to the similarity between the color reaction of some substances in the glands and those of pyrocatechol.

(c) Abel did not first demonstrate that these glands contained a substance of marked physiologic activity, for Oliver and Schäfer (*Jour. Physiol.*, 1894, xvi, 1; 1895, xviii, 230) in 1894 made the important discovery that the extract from the suprarenal glands produced a rising blood-pressure when injected intravenously. Moreover, Moore (*Proc. Physiol. Soc.*, London, xiv; *Jour. Physiol.*, 1895, xvii) in 1895 discovered that the reducing property in such an extract went hand in hand with the ability to increase the blood-pressure, and he also concluded that the physiologically active body must be identical with the reducing body which gives a green color reaction with the iron salts.

(d) In 1896 Fränkel (*Wien. med. Bl.*, 1896, xix, 207, 228, 246) purified the extract of the glands until he had obtained a syrup-like body, and he, like Abel, with equal reason, considered this to be a pure substance. He called it "sphygmogenin," but no evidence was offered to demonstrate its purity or identity. In the light of our present knowledge we, of course, know that it was not the active substance, though it undoubtedly contained some of the active substances.

(e) Mühlmann (*Deutsch. med. Wchnschr.*, 1896, xxii, 409) in 1896 made a chemical investigation and arrived at the conclusion that the active principle was pyrocatechol. This, of course, we now know to be untrue also.

(f) Moore (*Jour. Physiol.*, 1897, xxi, 383) in 1897 argued that Fränkel was wrong in assuming the active principle to be a derivative of pyrocatechol, and argued that it was a derivative of pyridine. The error of this conclusion has also been demonstrated; nevertheless, Moore's work was important, very interesting and creditable.

(g) Abel and Crawford (*Bull. Johns Hopkins Hosp.*, 1897, viii, 151) in 1897 published results which showed that they had been carrying on a very interesting series of chemical researches on the active principle, but a careful perusal of the papers published at this time, and also in 1898 and 1899, and, in fact, a perusal of all the papers which have emanated from Professor Abel, has demonstrated that he never did succeed in isolating the active substance in pure form, but that what he did obtain and what he did regard as the active principle and the substance to which he has given the name of epinephrin, was really a compound which was not the active principle itself, but which contained more or less of the active principle, and which consequently displayed some of the peculiar physiologic activity of this substance. Aside from the greater complication of the work, and perhaps the more highly scientific methods used, he really accomplished little more than did Fränkel in 1896, or perhaps Oliver, Schäfer and Moore, who made an extract from the glands and proved it was possessed of peculiar chemical and physiologic activity. More than this, the work which he did and the results which he published were not finally used by Drs. Takamine, Aldrich, von Fürth or Pauly as the basis of a method for the extraction and purification of the active principle. Without the independent labors and discoveries of these other men or others equally as able and fortunate, it is quite possible that the active principle of the suprarenal glands in a pure and concentrated condition would not be available to the medical profession to-day.

(h) If Abel has ever succeeded in extracting the pure active principle, even up to the present day, without taking advantage of the information developed by Takamine and others, we have seen no evidence of it in the scientific journals. There is no doubt that Abel was convinced that these glands contained some substance possessing high physiologic potency; in fact, he could not have avoided such a conclusion from the information furnished by others, and one might perhaps say with all justice that he assigned the name epinephrin to the substance which he imagined was present in the glands, but his conclusions as to the constitution of this substance, and the methods which he developed for its extraction and purification, have been overthrown by others and are not accepted to-day by his scientific colleagues.

Subdivisions i j and k are commented on below.

(*i*) No less than four formulas for the active principle of the suprarenal glands have been proposed by Abel from time to time. Even if we agree to adopt the last of these, one cannot avoid the fact that this has been proved beyond any doubt to be an incorrect formula for the active principle. It would certainly do violence to scientific usage, and be a distortion of the truth, therefore, to apply this name "epinephrin" to a substance now known as "adrenalin," which has a different chemical constitution.

Comment:—In justice to Abel, it should be said that he conceded that he had not isolated the natural base, but its benzoyl salts. These, however, he evidently had in a practically pure form—as pure as Takamine's original products. In evidence, we need only quote Aldrich, and therefore Parke, Davis & Co. themselves: "It is interesting to note in this connection that if we subtract a benzoyl residue from Abel's formula for epinephrin—$C_{17}H_{15}NO_4$—we obtain a formula—$C_{10}H_{10}NO_3$—which is not very far removed from that of adrenalin—$C_9H_{13}NO_3$—a difference that can be readily explained if we suppose either of these bodies to be contaminated with other bodies." (*Am. Jour. Physiol.*, v, p. 461). As to the matter of formulas, it must be remembered that the time when Abel worked on the problem, the subject was scarcely ripe for final judgment. Every chemist understands that the earlier formulas are more or less provisional. A criticism on this score is scarcely fair, least so from the champions of Dr. Takamine; for *the formula of Takamine has shared the same fate as Abel's*. In fairness, it should also be stated that the four formulas which excite the derision of Parke, Davis & Co., were not all for one and the same thing.

Parke, Davis & Co. then quote the opinions of several investigators:

> (i) Professor Pauly (*Ber. d. deutsch. chem. Gesellsch.*, 1903, xxxvi, 2944), a man of world-wide reputation, writing from the laboratory of the University of Bonn, says:
>
> "The credit of first precipitating and isolating from the suprarenal gland of the therein contained blood-pressure-raising principle as a chemical individual belongs to Takamine. It has the name 'adrenalin,' given to it by its discoverer, which name, among the many trivial names given to it, possesses the best scientific claim."
>
> (j) Professor von Fürth (*A. d. Sitzungsb. d. k. Akad. d. Wissensch. in Wien. Mathem-Naturw. Klasse*, 1903, cxii, 3) says in this connection:
>
> "Abel and his pupils employ the name of epinephrin to designate the active principle as contained originally in the gland, instead of adrenalin or suprarenin. As the substance described and analyzed by Abel under the name epinephrin is certainly different from the original body in the adrenal glands, I shall avoid using the same, since it necessarily leads to a misunderstanding."
>
> (k) In a second paper Pauly (*Ber. d. deutsch. chem. Gessellsch.*, 1904, xxxvii, 1388) emphatically rejects Abel's empirical formula, $C_{10}H_{13}NO_3\tfrac{1}{2}H_2O$, and remarks:
>
> "This formula, together with the name 'epinephrin hydrate,' which designates the same, should be blotted out of the literature. The name 'epinephrin,' however, should remain now as before for the basic substance obtained by treating adrenalin with concentrated H_2SO_4, or with dilute acids under pressure, and to this the formula $C_{10}H_{13}NO_3$ should be given. This body, whose chemical composition is different from adrenalin, and whose physical, chemical and pharmacologic properties are different from the real blood-pressure-raising substance, should be considered a transformation product of the active principle."
>
> Pauly adds that Jowett is mistaken in giving Abel and Crawford credit for the priority in first isolating the active principle:
>
> "Thus there can be no doubt that not Abel and Crawford, but Takamine first obtained the active substance. If Abel adheres to the statement referred to in the beginning, that his formula $C_{10}H_{13}NO_3\tfrac{1}{2}H_2O$ finds confirmation in the analyses of salts and derivatives, it must be answered that this is not the case; that he, outside of one impure benzoyl product, has not *prepared, not to* say analyzed, up to the present time, either a salt or derivative of adrenalin, in which the nucleus of the last is still intact."

Comment:—These are altogether matters of opinion or point of view, and to appraise them, it should be understood that Pauly, at the time when he wrote them, was engaged in a somewhat sharp controversy with Abel, as might be gathered from the expressions quoted. His views, therefore, would be apt to lack perspective, in fact, they would tend to be somewhat biased. Incidentally, Pauly is not a professor but a privat docent at the University of Würzburg and can hardly be said to be a "man of world-wide reputation as a chemist." As to von Fürth's statement, there can no longer be any fear of a "misunderstanding."

Parke, Davis & Co. proceed:

> (m) Abel's epinephrin possessed little if any blood-pressure-raising action (von Fürth: *Ztschr. f. physiol. Chem.*, 1900, xxix, 122). Abel never succeeded in producing the crystallized base until he learned how from Takamine. The *one point on which* Abel (*Bull. Johns Hopkins Hosp.*, March, 1901, xii, 80) at first agreed with von Fürth (most erroneously, as it proved) was that "the active principle *in its native* state is not precipitated by ammonia." Not only was this single *point* of agreement exploded by Dr. Takamine's discovery, but singularly enough Abel's statement of the error was made in the same article of May, 1903, in which he acknowledged receipt of the Takamine crystalline base, of which he then did not know the process *of making*. In other words, Abel never succeeded in *producing* the crystalline preparation of the blood-pressure-raising principle until Takamine taught him how by a method which he *and von Fürth had* pronounced impossible! Abel remarks later (*Ber. d. deutsch. chem. Gesellsch.*, 1903, xxxvi, 1839): "The important observation that the substance can be precipitated in crystalline *form from* concentrated gland extracts by the aid of ammonia and other alkalies we owe to Takamine." Nothing *could be more* explicit.

Comment:—As to the ammonia-precipitation, the *fact that* Takamine succeeded where Abel and von Fürth had failed, proves that Abel was wrong in this particular, as he concedes in the quotation. Abel fell into this error because his gland solutions were too weak; he had, however, discovered the ammonia-precipitation in the case of his isolated substance, and the basic nature of the latter long before a report of Takamine's work was published. (*Hoppe-Seyler's Ztschr.*, 1899, xxviii, 324.)

The statement that "Abel's epinephrin never possessed any blood-pressure-raising action," is a wholly inexcusable misrepresentation, to put it mildly. Abel stated that his free base soon lost its activity, but the salts, especially the picrate and bisulphate, were highly active, *and in the dry state retained* their activity. These active salts, as epinephrin bisulphate, were always prepared by transposition from a picrate and not from the free epinephrin which became inactive presumably by *oxidation* during the precipitation. The curves in the paper of Abel and Crawford (*Johns Hopkins Hospital Bull.*, 1897, viii, 151) *were absolutely convincing*. In the paper in *Hoppe-Seyler's Zeitschrift*, xxv, Abel found that 0.02 mg. of the salt per kilo of animal gave a distinct rise; and that larger doses raised the pressure by 88 mm. On p. 349, he also describes the blanching effect on the conjunctiva. The writer of the "reply" is evidently familiar with these papers and his misstatement of the case must, therefore, be intentional, especially since he admits in a former paragraph (g), that Abel's epinephrin "displayed some of the *peculiar physiologic* activity of this substance" (the active principle). Nor does this writer anywhere intimate that Abel has *replied in detail* to von Fürth's contention that epinephrin and suprarenin (the name adopted by von Fürth for the active principles *of the* suprarenal gland, now a "trade" name) are fundamentally different substances. (See Abel, *Johns Hopkins Hospital Bulletin*, March, 1901, and *American Journal of Pharmacy*, July, 1903.)

IV. SUMMARY

Parke, Davis & Co., conclude their reply as follows:

> (n) Far be it from us to pretend that our research workers were *not greatly indebted* to other pioneer students of the suprarenal gland, or to deny that the work of a number of earnest investigators had paved the way for Takamine's crowning *achievement*. Nearly every great invention or advance in every art is thus made possible. Pasteur made Lister possible. Is this any disparagement of Lister? Because there was a prior record of *research, are we to be robbed* of the credit which is justly due us for being the first, through our employees, to separate the *active* principle in its pure state, to determine its constitution, to evolve *a practical method of production* on a commercial scale, to confer a remarkable boon on suffering humanity? Is the inventor of a therapeutic agent to be discriminated against? Has *society a greater stake* in *an improved* broom-handle than in a valuable drug? Nay, of all inventions, should not the author *of* a new remedy be singled out for the richest rewards that society can *confer? Will Professor* Ehrlich be any the less a great benefactor of his race if he reserves for himself or for his institute in Frankfort a large royalty on his wonderful salvarsan? *If we have* done nothing for medicine and humanity in this matter of adrenalin, your argument is sound. If we have done much, your position is pitiful and wrong. And, worst of all, *the very men* whom you profess to serve—the medical practitioners of the country—will be the first to suffer. The more you encourage the use of the blanket name "epinephrin," the more *you put the physician* at the mercy of "thirty or forty" different manufacturers whose products range in value from the worthless to the best.
>
> Parke, Davis & Co., Detroit.
> By E. G. Swift, General Manager.

Comment:—We commend the spirit of the *first sentence*. For the rest, we need only restate the *principle* at issue, which Parke, Davis & Co. have seen fit to ignore entirely in their reply: When the same substance is actually marketed and used under several distinctive trade-names, it becomes necessary to use a generic name when speaking of properties of the substance which are common *to all "brands."* This is the intent of most scientific and medical writers on the suprarenal base, and when the word "adrenalin" *is used* by medical writers, it is generally meant in the generic, and not in the distinctive sense. Since the name "adrenalin" is protected, it should not, and properly cannot, be used in this way. The name "epinephrin," since it is not monopolized, is not only the best, but also the sole name which can be rightly applied to the suprarenal base, in the generic sense.

Correspondence

Rheumatism, Specialism and Independent Journalism

To the Editor:—I saw a very timely letter in THE JOURNAL, March 11, 1911, inquiring why reputable physicians and surgeons will contribute articles to medical journals which admit a very undesirable class of nostrums and proprietaries to their advertising. As I frequently contribute to several independent journals, some of whose advertisements I do not approve of at all, I will say that I do it in order to reach the large number of broad, progressive, and liberal and non-sectarian mediical men who read these journals and keep watch for everything new or good that appears in their columns. I do not use nostrums or proprietaries, never have used any and always speak out against them whenever I have an opportunity, but I must have a fair field and a free parliament which no man could have in contributing for journals like THE JOURNAL A. M. A.

I am a specialist in the treatment of rheumatism and diseases of the stomach and liver and diseases of children, and have been grandly successful, more so than I ever dreamed possible when I started in the practice of medicine. I like to spread the light, and tell other doctors what I have done and what they can do by using the same means, but you would not think for a moment of admitting one of my articles to the columns of THE JOURNAL A. M. A., for I often carry a case of rheumatic fever to a very quick and successful termination with such remedies as bryonia, iris, rhus tox., pulsatilla, gelsemium, colchicin, veratrum, aconite, apocynum and guaiacum.

I demand that any journal that I write for shall be broad and liberal and non-sectarian enough to publish articles recommending any ethical remedy that I have proved to be of positive curative value. We need a much higher standard of medical ethics. They are absolutely disregarded by most medical men now. A poor sick doctor in South Carolina writes to me in asking advice for his desperate case of rheumatism, "I have paid out everything but my home to the M.D.'s for treatment and am not cured." What kind of ethics would allow a man to take the last dollar from a suffering brother physician? W. M. GREGORY, Berea, Ohio.

The Niemeyer Pill

To the Editor:—The "Niemeyer Pill," concerning which there has recently been an interesting correspondence in THE JOURNAL [January 21, p. 211 and February 11, p. 443], is commonly known in England as Addison's pill. That it was used long before Niemeyer's time is proved by its inclusion in the first *edition of the Pharmacopeia of Guy's Hospital*, published in 1837, when Bright was one of the full physicians and Addison the only assistant at the hospital. The pill was then called pilula scillæ cum hydrargyro and its composition is as follows:

℞ Hydrargyri oxidi gr. xx.
Pilularum scillæ compositarum dr. iv.
Misce. et divide in pilulas lx.
Dosis, i, ii, vel iii, semel, bis, sæpiusve quotidie.

The following is the formula of the pilula scillæ composita:

E singulis drachmis scillæ formentur pilulæ xii.
Dosis, i, ii, vel iii, bis, ter, quaterve quotidie.
Singulis pilulis interdum adde.
Digitalis foliorum contritorum gr. ss.

ARTHUR F. HERTZ, London, Eng.

Anterior Poliomyelitis: The Proper Method of Diagnosis

To the Editor:—In a letter to the *New York Medical Journal*, published several years ago, I made the suggestion, from analogy, that the first tonsil (Luschka's) was probably the site of infection in poliomyelitis. Dr. Bryant's recent article has confirmed this probability.

In a recent number of THE JOURNAL, Dr. Flexner reports that he and his collaborators have suggested that the nasopharynx acts in human beings as the portal of entry of the virus into the central nervous system, as well as the source of its dissemination to other human beings. He also calls attention to the work of Osgood and Lucas showing that the virus can survive in the nasopharynx of the monkey for nearly six months. . . The importance of securing methods of early and certain diagnosis of anterior poliomyelitis, says Flexner, is self-evident. By taking advantage of the changes which regularly occur in the cerebrospinal fluid it is possible, early in the course of the infection, to arrive at a certain diagnosis.

As it would be comparatively easy both to diagnose and to treat this disease by going at once to the place which is now known to be the site of infection in this and in all air-borne infections, I would suggest the following method: In a patient suspected of harboring the germs, sterilized cotton carriers should be inserted through the nose to the nasopharynx. These infected carriers with their bits of cotton are returned to the tubes and later used to infect either monkeys or guinea-pigs. This procedure of passing the cotton into the nasopharynx suggests the proper method of sterilizing this space, namely by wetting the cotton in hydrogen peroxid.

EDMUND D. SPEAR, M.D., Boston.

The Secret Commission Evil

To the Editor:—I read in THE JOURNAL, March 11, Dr. Lord's article on "The Secret Commission Evil."

I have been making furrows in these muddy country roads for seven winters and have driven through the dust for seven summers. On my rounds I have seen and studied many cases. On one occasion I was sent to consult a big surgeon concerning a case which was causing a great deal of worry to the whole family. I saw the surgeon, and after our consultation, I was asked: "Where do you send your surgical cases?" I proudly answered, "I operate whenever I can get the consent of the patient, doctor." This surgeon did not take me along to dinner, although he had remarked previously that he was on his way, nor did he seem to enjoy my company thereafter.

On another occasion, an old classmate introduced me to some of his specialist friends. They also asked: "Where do you send your patients?" I answered: "My territory is pretty far away, doctor." Our visit was perceptibly less sociable afterward. What would the proposition have been if the answers had been more pleasing to the surgeon and the specialists?

I feel that I missed some good entertaining or perhaps "fee-splitting." Maybe these gentlemen needed finances more than patients. Where does "fee-splitting" start?

AUGUST BECHTOLD, M.D., New Athens, Ill.

Queries and Minor Notes

ANONYMOUS COMMUNICATIONS will not be noticed. Every letter must contain the writer's name and address, but these will be omitted, on request.

REMOVAL OF IMPACTED CERUMEN FROM EAR

To the Editor:—I have been interested in the query of Dr. Blackly, in THE JOURNAL, March 11, regarding removal of impacted cerumen from ear. Filling the ear at night with olive oil and following this by hot irrigation next morning with biborate of soda solution will remove the impaction very easily. The patient is advised to sleep with the affected ear uppermost. If the opposite ear is also in need of attention the same treatment may be used on the following night. ERNEST BOSTON, M.D., Taylor, Texas.

ODOR FROM ASPARAGUS

To the Editor:—What is the peculiar odor noticed in urine after eating asparagus? Have any harmful effects been known as a result of eating this vegetable? I have a faint recollection of hearing a medical instructor caution against its use in kidney disease.

A. I. L.

ANSWER.—The odor in urine after eating asparagus is due to asparagin—a crystalline substance which exists in smaller quantities also in lettuce, potato, marshmallow and other vegetables and is said to have diuretic and sedative properties. The eating of asparagus is not generally thought to have harmful effects.

BACTERIOLOGY OF COLDS

To the Editor:—Please give me the facts known with regard to the bacteriology of "colds." Is the influenza bacillus usually responsible for ordinary colds or are other germs sometimes the cause? Also, does the infection spread along the mucous membrane from the first site or is the blood concerned in its propagation?

B. S. Penn, Humboldt, Tenn.

Answer.—The actually known facts regarding the relations of bacteria to "colds" are somewhat meager. It is believed by many authorities that the essential factor in a "cold" is congestion due to vasomotor changes, not necessarily connected with bacterial action, the association of bacteria with such changes being merely secondary. Other "colds" follow the direct action of irritants, prominent among which may be bacteria-laden dust. In other cases there is proliferation of bacteria already domiciled on the mucous membrane. The ordinarily latent microorganisms spring into renewed activity when the resisting power of the individual is diminished. A number of organisms have been found in the nasal secretions in "colds." Among these may be mentioned *Micrococcus catarrhalis,* streptococci, staphylococci, the pneumococcus, an unnamed diplococcus and the influenza bacillus. Some "colds" are evidently contagious, but their microbic cause has not been discovered. The influenza bacillus does not seem to be usually responsible for ordinary "colds." Even in epidemics, characterized by the symptoms of influenza, the influenza bacillus has not been demonstrated in all cases. So far as clinical observation goes, it would appear that the infection spreads by contiguity along the mucous membrane in most cases. An infection by way of the blood is possible, not probable.

CHINESE DO NOT PAY PHYSICIANS TO KEEP THEM WELL

To the Editor:—Ever since I was a boy I have met with occasional references in books and newspapers to the "Chinese custom of paying their physician when they are well and stopping payment when they are sick." Is there any truth in this statement? Has this been the custom in China, or is it merely a traveler's yarn or a utopian fancy?

C. U. S.

Answer.—Contracting to keep a patient in health is at least extremely rare in China. All authorities acquainted with China agree that the method is so seldom met with as practically not to exist. Were there such a custom the physician (though that is hardly the term to apply to the native malpractitioner) would promptly go out of business, for his clientele would speedily develop real and imaginary cause for reducing his income to zero. The misstatement is often seen in the literature, but must be classified with the fabrication that the Chinese eat rats, or that they did not wear long hair 'till compelled to do so by the Manchu conquerors.

TREATMENT OF ACIDOSIS

To the Editor:—Please give the most satisfactory treatment, both dietetic and medicinal, for acidosis.

I. W. C.

Answer.—Acidosis is due primarily to insufficient oxidation, and secondarily to an insufficient supply of carbohydrates, the organism being obliged in that case to break up proteins or fats to sustain life. The dietetic remedy, therefore, is a supply of carbohydrates sufficient to spare the fats which are regarded as the chief source of the acid. In diabetes this supply of carbohydrates should be sufficient to avoid the dangers of acidosis but not enough to increase to a dangerous extent the amount of sugar in the blood and urine. Medicinally it is theoretically correct to administer remedies which will increase oxidation. Alkalies are believed to have this power and are the chief remedies employed in the treatment of acidosis.

The Public Service

Medical Department, U. S. Army

Changes for the week ended March 18, 1911.

Lowe, Thomas S., M.R.C., ordered to proceed from Whipple Barracks, Ariz., to Fort Apache, Ariz., for temporary duty.

Jones, George B., M.R.C., left Fort Benjamin Harrison, Ind., with the 10th Infantry, en route to Fort Sam Houston, Texas.

Vose, William E., major, left Jackson Barracks, La., with 164th Co. Coast Artillery en route to Galveston, Texas.

Holmes, R. W., lieut., left Plattsburg Barracks, N. Y., with troops en route to Texas.

Whitcomb, C. C., and Crabtree, George H., majors, promoted to major, Medical Corps, to rank from Jan. 1, 1911.

Kelly, John P., M.R.C., ordered to Fort Hamilton, N. Y., for duty.

Marietta, Shelley U., M.R.C., resignation accepted by the President.

Walker, Thomas C.; Koyle, Fred T., and Eliot, Henry W., M.R.C., ordered to proceed to Newport News, Va., for assignment to duty on transports.

Haywalt, George W., M.R.C., is honorably discharged from the service of the United States, his services being no longer required.

Hoff, John Van R., colonel, ordered to proceed to Albany N. Y., to read a paper at the meeting of the Medical Society of the State of New York, on or about April 18 and 19, 1911, on the subject of "Experience of the Army with Vaccination as a Prophylactic Against Small-pox."

Hess, Louis T., major; Weed, Frank W., captain; Burket, John A., and Fisk, Owen C., lieuts., ordered to proceed to Galveston, Texas, and report for duty with the field hospital to be organized at that place.

Reynolds, F. P., major, in addition to his other duties will perform the duties of medical superintendent of the transport service at Newport News, Va.

O'Connor, C. H., major, ordered to proceed to San Antonio, Texas, and assume command of Ambulance Co. 38, to be assembled at that place.

Field, Peter C., major, granted leave of absence for two months, about June 1, 1911.

Johnson, Thomas H., lieut., left Fort Baker, Cal., en route to San Diego, Cal., for duty with 30th Infantry.

Gilchrist, H. L., major, reports for duty at Fort Sam Houston, Texas.

Etter, Harry B., lieut., left Fort Snelling, Minn., with 2d Squadron, 4th Cavalry, en route to El Paso, Texas.

Campbell, George F., M.R.C., left Fort Wingate, N. Mex., en route to Fort Sam Houston, Texas, with Co. A, 18th Infantry.

Hanson, Louis H., captain, left Fort Hamilton, N. Y., with troops en route to Texas.

Knox, Howard A., lieut., left Fort Hancock, N. J., with troops en route to Texas.

Gosman, George H. R., major, left Fort Barrancas, Fla., en route to Galveston, Texas, with 15th and 20th Cos. Coast Artillery.

Hutton, Paul C., major, left Fort Snelling, Minn., with the 28th Infantry, en route to Fort Sam Houston, Texas.

Bowen, A. S., lieut., and Maynard, E. B., M.R.C., left Fort Snelling, Minn., with the 28th Infantry, en route to Fort Sam Houston, Texas.

Patterson, Robert U., major, left Fort Banks, Mass., en route to San Antonio, Texas.

Long, Charles J., D.S., reports for temporary duty at Fort Constitution, N. H.

Phillips, Hiram A., lieut., left Fort Banks, Mass., en route to Fort Monroe, Va.; reported March 10 for duty on the *McClellan.*

Hopwood, L. L., captain, left Fort Monroe, Va., en route to Galveston, Texas.

Mount, James R., lieut., left Fort Sheridan, Ill., en route to St. Louis, Mo., for temporary duty at supply depot.

Rich, Edward W., captain, reported for duty with the 4th Reg. Prov. Coast Artillery, presidio of San Francisco, Cal., for duty in field.

Welles, E. M., Jr., lieut., left presidio of Monterey with troops for duty at San Diego, Cal.

Wales, Philip C., major, left presidio of Monterey with troops en route to San Diego, Cal.

Eckwurzel, George M., major, left Fort Mackenzie, Wyo., with headquarters and two battalions of 18th Infantry en route to Texas.

Van Poole, Gideon M., major, left Fort Sheridan, Ill., en route to Fort Brady, Mich., for temporary duty.

Ragan, Charles A., captain, relieved from treatment at the Walter Reed General Hospital, Takoma Park, D. C., and from further duty in the Philippines division and assigned to temporary duty at the Walter Reed General Hospital.

Cole, Blase, M.R.C., resignation accepted by the President.

Manly, C. J., major, now at San Antonio, Texas, will proceed without delay to Galveston, Texas, and report to the commanding general, 1st Separate Brigade, for assignment to duty.

Davis, William B., col., granted leave of absence for two months and nine days, to take effect on his arrival in San Francisco, Cal.

Purnell, Harry S., captain, ordered to the Army General Hospital, San Francisco, Cal., for duty.

Bartlett, William H., captain, ordered to proceed from San Antonio, Texas, to Fort Oglethorpe, Ga., for temporary duty.

Richardson, William H., captain, reported for duty to commanding officer, 4th Prov. Reg. Art., at presidio of San Francisco, Cal., for field duty.

Tuttle, George B., M.R.C., left San Francisco, Cal., for duty in the field.

Ashburn, James A., M.R.C., left Fort Assiniboin, Mont., accompanying troops to Fort D. A. Russell, Wyo.

Hartsock, F. M., major, reports arrival at San Antonio, Texas.

Baker, David, major, and Darby, Taylor E., lieut., report arrival at camp near Fort Sam Houston, Texas., with the 17th Infantry.

Frick, Euclid B., lieut.-colonel, and Tasker, Arthur N., lieut., left presidio of San Francisco en route with the 30th Infantry to San Diego, Cal., for field service.

Fletcher, John P., lieut., left Fort D. A. Russell, Wyo., with the 9th Cavalry to Fort Sam Houston, Texas.

Dutcher, Basil H., major, reports arrival at San Antonio, Texas, to assume command of the field hospital.

Fauntleroy, P. C., major; Beery, Harry R., lieut., and Jones, George B., M.R.C., report arrival at Camp San Antonio, Texas, with the 10th Infantry.

Mills, Fred H., M.R.C., left Fort Missoula, Mont., en route to Fort Assiniboin, Mont., detached duty.

Reynolds, F. P.; Fauntleroy, P. C.; Clayton, Jere B.; Bispham, William N.; Dean, Elmer A., majors; Bevans, James L., and Thomas, Henry D., captains. Orders directing the above officers to take a course of instruction at the Army Field Service School for Medical Officers, Fort Leavenworth, Kan., is revoked.

Stone, Frank P., D.S., left presidio of Monterey, en route to Fort Rosecrans, Cal., for temporary duty.

Long, Charles J., D.S., reported for temporary duty at Fort Williams, Maine.

Medical Corps, U. S. Navy

Changes during the week ended March 18, 1911.

Morris, L., surgeon, detached from the naval supply depot, navy yard, New York, and ordered to the *Hancock.*

Benton, F. L., surgeon, detached from the *Franklin* and ordered to the *Idaho.*

Plummer, R. W., surgeon, detached from the *Idaho* and ordered to the *Franklin.*

Cook, F. C., surgeon, detached from the *North Carolina* and ordered home to await orders.

Sykes, J. R., P. A. surgeon, detached from the Naval Medical School Hospital, Washington, D. C., and ordered to the navy yard, Portsmouth, N. H., and to additional duty in connection with the *Southery, Topeka*, and naval hospital at that place.

Old, E. H. H., P. A. surgeon, detached from the Naval Medical School Hospital, Washington, D. C., and ordered to the *North Carolina*.

Hoyt, R. E., P. A. surgeon, detached from the Naval Hospital, Mare Island, Cal., and ordered to the *Buffalo*.

McDowell, R. W., asst.-surgeon, detached from the Naval Academy and ordered to the Bureau of Medicine and Surgery, Navy department.

Michels, R. H., A. A. surgeon, appointed acting assistant surgeon from March 10, 1911.

Richardson, R. R., surgeon, detached from the *Prairie* and ordered to the *Virginia*.

Ohnesorg, K., surgeon, detached from the *Virginia* and ordered to the *Prairie*.

Crandall, R. P., surgeon, detached from the *Hancock* and ordered to treatment at the Naval Hospital, New York.

U. S. Public Health and Marine-Hospital Service

Changes for the seven days ended March 15, 1911.

Anderson, J. F., P. A. surgeon, directed to proceed to Trenton, N. J., on special temporary duty.

Collins, G. L., P. A. surgeon, directed to proceed to Boston, and report to the medical officer in command for duty and assignment to quarters.

Salmon, T. W., P. A. surgeon, granted six months' leave of absence from April 18, 1911, without pay.

Frost W. H., P. A. surgeon, directed to proceed to Savannah, Ga., on special temporary duty.

Simpson, Friench, P. A. surgeon, granted fifteen days' leave of absence from March 20, 1911.

DeForest, C. M., A. A. surgeon, granted two weeks' leave of absence from April 25, 1911, without pay.

Duke, B. F., A. A. surgeon, granted fifteen days' leave of absence from Feb. 14, 1911, on account of sickness.

Horning, Henry, A. A. surgeon, granted seven days' leave of absence from March 8, 1911, under paragraph 191, Service Regulations.

Kuhn, C. F., A. A. surgeon, granted thirty days' leave of absence from April 15, 1911, with pay, and two months without pay, from May 15, 1911.

Weeks, A., A. A. surgeon, granted thirty days' leave of absence from March 6, 1911.

Wright, F. W., A. A. surgeon, granted eight days' leave of absence from March 18, 1911.

Board of medical officers convened to meet at the Marine Hospital, Portland, Maine, on call of the chairman, to conduct a medical survey of an officer of the Revenue Cutter Service. Detail for the board: Surgeon C. E. Banks, chairman; Surgeon J. M. Eager, recorder.

Society Proceedings

COMING MEETINGS

American Medical Association, Los Angeles, June 27-30.

Alabama, Medical Society of the State of, Montgomery, April 18.
Am. Assn. of Pathologists and Bacteriologists, Chicago, April 14-15.
American Gastro-Enterological Assn., Philadelphia, April 19-20.
California, Medical Society of State of, Santa Barbara, April 18.

Georgia, Medical Association of, Rome, April 19-21.
Maryland, Med. and Chirurgical Faculty of, Baltimore, April 25-27.
Mississippi State Medical Association, Jackson, April 11.
New York, Medical Society of the State of, Albany, April 18.
South Carolina Medical Association, Charleston, April 19-21.

ASSOCIATION OF AMERICAN MEDICAL COLLEGES

Annual Meeting, held in Chicago, Feb. 27-28, 1911

(Continued from page 844)

The address of the president, Dr. John A. Witherspoon, will appear in full in The Journal.

Entrance Requirements for Admission to the Medical Course

Dr. George Edwin MacLean, President of the University of Iowa: The entrance requirements should be met absolutely without conditions. The work of the medical college is so heavy that the student should not be permitted to drag any entrance conditions after him. The success of the instruction in the first year is imperiled if the student must divide his attention between his current studies and back work. The abolition of conditions removes opportunities for college authorities, overzealous about attendance, or tempted to dishonesty in administration, to evade the published requirements. If the ideal requirement is adhered to, not less than two years of college work, there is little or no sense for one to seek admission to the medical school with a condition.

I would have the *preliminary education* consist of graduation from an accredited high school, *normal school* or academy plus two years taken in an accredited college of liberal arts, with a course of at least one year each devoted to physics, chemistry and biology. The entrance requirements to the collegiate work should be made more flexible, the number of *specifically* required subjects in the secondary education being reduced in view of the fact that the two years in liberal arts round out the four years of the secondary school. In the period of six years there should be *not less than* two years of Latin or Greek, or four years of modern languages with the elements of Latin grammar, two years of mathematics, two years of English, one year of history and one year each of physics, chemistry and biology, preferably done in college. If temporarily, some schools must be allowed the liberty of admitting on a four-year high school basis, and therefore think it necessary to *specify* rather particularly certain entrance requirements, might it *not* be *possible* to permit such colleges as require the two years of collegiate study for admission not to require specific subjects beyond Latin, physics, chemistry and biology? Practically every high school student will offer a reasonable amount in English, history and mathematics. The wider range of time given in which to complete the required subjects would largely do away with the evil of estimating equivalents and the frauds sometimes perpetrated in these estimates. This would also gain time for the extension of the professional courses, including hospital work.

The unit of measurement should be the "unit." Such terms as "count," "point" and "credit" should be discontinued. With reference to examinations, I would suggest that they total not less than fifteen units in required and elective subjects. I would select major topics in the four fields of language and literature, history, mathematics and science, instead of giving detailed examinations in all the subjects enumerated. The examiner should be an expert university or college examiner meeting the few individuals who have prepared by tutoring or in unaccredited schools or through misfortune and age, come up without institutional training. He should size up these personalities in connection with all the records presented and use his discretion in giving a chance for these individuals in the college of medicine. We must preserve opportunities for individuals in this day of emphasis or institutionalism. The examiner can be depended on to conserve standards.

The entrance requirements, then, should be fifteen units of secondary school work in an accredited school, plus thirty hours of college work, the secondary and collegiate work embracing the required subjects of not less than two units of Latin or Greek, or four units of modern languages, provided an examination is passed in the elements of Latin grammar, two units of mathematics, one unit of history, two units of English, one unit or year hour each of physics, chemistry and biology. The candidate for admission should not be permitted to enter the college of medicine with conditions. The administration of these standards is to be by boards empowered by statute to administer them, and by accredited schools and colleges, and by authorized examiners not members of the medical colleges concerned.

DISCUSSION

Dr. Egbert LeFevre, University of Bellevue Hospital Medical College: One of the biggest stumbling blocks in the way of the medical colleges is the attitude of the universities not connected with the state toward this two-year college requirement. In the West the high school and university courses are correlated. In the East there is no such correlation. We have dissociated universities and colleges so that there is a great impediment to students passing from one to the other, and that makes it doubly hard for a high school pupil to get two years of college work and then pass smoothly into college work. We demand an intensive course preparatory to a professional education which cannot be given in the professional or technical school, but in making this demand we place our students at a disadvantage because of this attitude on the part of the universities who do not wish to modify their curriculum to suit these two-year men. Until they accept it as a part of their duty to correlate their entrance requirements with the generally accepted and accredited high schools, there is going to be great difficulty in advancing men from the high school into the college to meet the requirements Dr. MacLean has mentioned.

Dr. Randolph Winslow, University of Maryland: I wish to endorse the suggestion that any man who has been unfortunate enough not to be able to secure the necessary collegiate training should have the right to get a medical education if he is capable.

Dr. H. D. Arnold, Boston: I think we may admit that the strict regulations which we have tried to place about our examinations are due to the fact that we are not living up to our present standards. What we need more than anything else is a minimum that will be lived up to.

Dr. J. S. Ferguson, Cornell University: It seems to me anomalous that the same effort that tends to elevate the degree of M.D. should lower the degree of A.B. If we would endeavor to exercise our influence with the colleges not to do that, we would be able to secure preparatory medical courses in the non-state-supported institutions.

Dr. Arthur Dean Bevan, Rush Medical College: Modern medicine demands a certain preliminary training. It demands that a man have a well-rounded secondary school education and a training in chemistry, physics and biology. The colleges which do not require that are doing poor, inefficient work in the light of the demands of modern medicine. Medical education also demands one year of practical training in a hospital where the student is part of the hospital machinery for the care of patients.

Administration of Entrance Requirements

Dr. B. D. Harison, Michigan State Board of Registration in Medicine: The proper method of administering requirements is by the board itself, covering credentials and credits, and in the event of an applicant not having the required qualification, he should be referred to a board of preliminary examiners, consisting of not less than four high school principals or superintendents for regular examination on the standard set by the board, covering a high school credential and its symmetrical features. This board reports its findings to the medical board. A properly constituted board of this kind will, in my experience, refuse the proper certificate to at least 75 per cent. of the applicants. This is not only an honest administration, but a practical one.

(To be continued)

AMERICAN CONFEDERATION OF RECIPROCATING EXAMINING AND LICENSING MEDICAL BOARDS

Ninth Annual Meeting, held in Chicago, March 3, 1911

The President, Dr. William A. Spurgeon, Muncie, Ind., in the Chair

Officers Elected

Dr. Spurgeon was reelected president and Dr. B. D. Harison, secretary; Dr. A. W. Alvord, Battle Creek, Mich., was elected vice-president.

Report of Secretary

Dr. Harison reported that the following states (fourteen) are now in membership in the confederation: Georgia, Indiana, Iowa, Kansas, Maryland, Michigan, Nebraska, Nevada, North Dakota, Ohio, Oklahoma, Utah, West Virginia and Wisconsin.

The following states (nineteen) reciprocate on the basis of the qualifications adopted by the confederation, but are not in membership: Arkansas, Colorado, Delaware, District of Columbia, Illinois, Kentucky, Louisiana, Maine, Minnesota, Missouri, New Hampshire, New Jersey, New York, South Carolina, Tennessee, Texas, Vermont, Virginia and Wyoming.

From Jan. 1, 1910, to Jan. 1, 1911, 1,000 reciprocal registrations were made by twenty-five states, 894 on the basis of Qualification No. 1 and 106 on the basis of Qualification No. 2.

Report of Committee on College Inspection

Dr. Spurgeon, chairman, reported that the following constituted the committee on college inspection: W. A. Spurgeon, Indiana, chairman; A. W. Alvord, Michigan; H. A. Barbee, West Virginia; H. H. Baxter, Ohio; I. H. Goss, Georgia; E. A. Carr, Nebraska; J. V. Stevens, Wisconsin. It was recommended that any inspection made be in the company of some representative of the state board of the state wherein the inspection was made, since each state board was the court of last resort regarding these matters in its own state. It was resolved also that the examiner should cooperate with the Council on Medical Education of the American Medical Association and with the Association of American Medical Colleges. The standard of rating was to be the standard adopted by the confederation in 1908.

Dr. J. V. Stevens, secretary, reported that it was decided to ask the colleges to pay the expense of the inspection. The work cannot be completed before the next meeting of the confederation, and no information can be given out now.

Report of Committee on Amalgamation with the National Confederation

Dr. Harison, chairman, reported that a conference was held with a committee from the national confederation in June, 1910, but that no definite action was taken at that time. It was considered desirable that the two confederations unite, but the basis for such a merger could not be made mutually agreeable then. The following communication bearing on this subject was then presented:

Chicago, March 2, 1911.

At the call of Dr. W. P. Harlow, dean of the School of Medicine of the University of Colorado, and president of the Association of American Medical Colleges, the following persons met in an informal conference for the purpose of discussing how a union of the two confederations of state examining and licensing boards might be effected:

Dr. Arthur Dean Bevan and Dr. N. P. Colwell, chairman and secretary, respectively, of the Council on Medical Education of the American Medical Association; Dr. Charles A. Tuttle and Dr. George H. Matson, president and secretary, respectively, of the National Confederation of State Medical Examining and Licensing Boards; Dr. William A. Spurgeon and Dr. B. D. Harison, president and secretary, respectively, of the American Confederation of Reciprocating Examining and Licensing Medical Boards; Mr. Abraham Flexner of the Carnegie Foundation for the Advancement of Teaching; Dr. William P. Harlow and Dr. Fred C. Zapffe, president and secretary, respectively, of the Association of American Medical Colleges.

On motion of Dr. Bevan, Dr. Harlow was made chairman and Dr. Zapffe secretary of the conference.

On motion of Dr. Bevan, seconded by Dr. Harison, it was voted that it be the sense of the conference that it is desirable that there be in this country one strong organization of state examining and licensing boards.

On motion of Dr. Matson, seconded by Dr. Colwell, it was voted that the name of such an organization might well be the National Federation of State Medical Boards.

On motion of Dr. Harison, seconded by Dr. Matson, it was voted that the membership of such an organization should consist of members, fellows and associates; that state boards only to be entitled to membership, with power to vote; ex-state board members to be elected to fellowship, without vote, and physicians, not members of an examining or licensing board, who are interested in medical education and state licensure, to be elected to associate membership (without vote) by a two-thirds vote of the members present at any meeting. Only fellows are to be exempt from the payment of dues.

William P. Harlow, Chairman.
Fred C. Zapffe, Secretary.

By a resolution presented by Dr. A. W. Alvord, it was voted that the president and secretary of the confederation with three others selected by the president constitute a committee to meet with a similar committee representing the national confederation for the purpose of effecting an amalgamation of the two organizations. The committee appointed consists of Drs. A. W. Alvord, Michigan; E. A. Carr, Nebraska; H. H. Baxter, Ohio; William A. Spurgeon, Indiana, and B. D. Harison, Michigan.

Cook, F. C., surgeon, detached from the *North Carolina* and ordered home to await orders.

Sykes, J. R., P. A. surgeon, detached from the Naval Medical School Hospital, Washington, D. C., and ordered to the navy yard, Portsmouth, N. H., and to additional duty in connection with the *Southern, Topeka*, and naval hospital at that place.

Old, E. H. H., P. A. surgeon, detached from the Naval Medical School Hospital, Washington, D. C., *and ordered to the North Carolina.*

Hoyt, R. E., P. A. surgeon, detached from the Naval Hospital, Mare Island, Cal., and ordered to the *Buffalo.*

McDowell, R. W., asst.-surgeon, detached from the Naval Academy and ordered to the Bureau of Medicine and Surgery, Navy department.

Michels, R. H., A. A. surgeon, appointed acting assistant surgeon from March 10, 1911.

Richardson, R. R., surgeon, detached from the *Prairie* and ordered to the *Virginia.*

Ohnesorg, K., surgeon, detached from the *Virginia* and ordered to the *Prairie.*

Crandall, R. P., surgeon, detached *from the Hancock* and ordered to treatment at the Naval Hospital, New York.

U. S. Public Health and Marine-Hospital Service

Changes for the seven days ended March 15, 1911.

Anderson, J. F., P. A. surgeon, directed to proceed to Trenton, N. J., on special temporary duty.

Collins, G. L., P. A. surgeon, directed to proceed to Boston, and report to the medical officer in command for duty and assignment to quarters.

Salmon, T. W., P. A. surgeon, granted six months' leave of absence from April 18, 1911, without pay.

Frost W. H., P. A surgeon, directed to proceed to Savannah, Ga., on special temporary duty.

Simpson, Friench, P. A. surgeon, granted fifteen days' leave of absence from March 20, 1911.

DeForest, C. M., A. A. surgeon, granted two weeks' leave of *absence from April 25, 1911, without pay.*

Duke, B. F., A. A. surgeon, granted fifteen days' leave of absence from Feb. 14, 1911, on account of sickness.

Horning, Henry, A. A. surgeon, granted seven days' leave of absence from March 8, 1911, under paragraph 191, Service Regulations.

Kuhn, C. F., A. A. surgeon, granted thirty days' leave of absence from April 15, 1911, with pay, and two months without pay, from May 15, 1911.

Weeks, A., A. A. surgeon, granted thirty days' leave of absence from March 6, 1911.

Wright, F. W., A. A. surgeon, granted eight days' leave of absence from March 18, 1911.

Board of medical officers convened to meet at the Marine Hospital, Portland, Maine, on call of the chairman, to conduct a medical survey of an officer of the Revenue Cutter Service. Detail for the board: Surgeon C. E. Banks, chairman; Surgeon J. M. Eager, recorder.

ASSOCIATION OF AMERICAN MEDICAL COLLEGES

Annual Meeting, held in Chicago, Feb. 27-28, 1911

(Continued from page 8[illegible])

The address of the president, Dr. John A. Witherspoon, will appear in full in The Journal.

Entrance Requirements for Admission to the Medical Course

Dr. George Edwin MacLean, President of the University of Iowa: The entrance requirements should be met absolutely without conditions. The work of the medical college is so heavy that the student should not be permitted to drag any entrance conditions after him. The success of the instruction in the first year is imperiled if the student must divide his attention between his current studies and back work. The abolition of conditions removes opportunities for college authorities, overzealous about attendance, or tempted to dishonesty in administration, to evade the published requirements. *If the ideal requirement is adhered to, not* less than two years of college work, there is little or no sense for one to seek admission to the medical school with a condition.

I would have the preliminary education consist of graduation from an accredited high school, normal school or academy plus two years taken in an accredited college of liberal arts with a course of at least one year each devoted to physics chemistry and biology. The entrance requirements to the collegiate work should be made more flexible, the number o specifically required subjects in the secondary education being reduced in view of the fact that the two years in liberal arts round out the four years of the secondary school. In the period of six years there should be not less than two year of Latin or Greek, or four years of modern languages with th elements of Latin grammar, two years of mathematics, tw years of English, one year of history and one year each o physics, chemistry and biology, preferably done in college. If *temporarily, some schools must* be allowed the liberty o admitting on a four-year high school basis, and therefor think it necessary to specify rather particularly certai entrance requirements, might it not be possible *to permi* such colleges as require the two years of collegiate study fo admission not to require specific subjects beyond Latin, physics, chemistry and biology? Practically every high schoo student will offer a reasonable amount in English, history an mathematics. The wider range of time given in which to complete the required subjects would largely do away with th evil of estimating equivalents and the frauds sometimes perpetrated in these estimates. This would also gain time fo the extension of the professional courses, including hospita work.

The unit of measurement should be the "unit." Such term as "count," "point" and "credit" should be discontinued. Wit reference to examinations, I would suggest that they tota not less than fifteen units in required and elective subject I would select major topics in the four fields of language an literature, history, mathematics and science, instead of givin *detailed examinations in all the subjects enumerated.* Th examiner should be an expert university or college examine meeting the few individuals who have prepared by tutoring o in unaccredited schools or through misfortune and age, come u without institutional training. He should size up these personalities in connection with all the records presented an use his discretion in giving a chance for these individuals i the college of medicine. We must preserve opportunities fo individuals in this day of emphasis or institutionalism. Th examiner can be depended on to conserve standards.

The entrance requirements, then, should be fifteen units o secondary school work in an accredited school, plus thirt hours of college work, the secondary and collegiate wor embracing the required subjects of not less than two units o Latin or Greek, or four units of modern languages, provide an examination is passed in the elements of Latin gramma two units of mathematics, one unit of history, two units o English, one unit or year hour each of physics, chemistry an biology. The candidate for admission should not be permitte to enter the college of medicine with conditions. The administration of these standards is to be by boards empowered b statute to administer them, and by accredited schools an colleges, and by authorized examiners not members of th medical colleges concerned.

DISCUSSION

Dr. Egbert LeFevre, University of Bellevue Hospital Medical College: One of the biggest stumbling blocks in the wa of the medical colleges is the attitude of the universities no connected with the state toward this two-year college requirement. In the West the high school and university course are correlated. In the East there is no such correlation. W have dissociated universities and colleges so that there is great impediment to students passing from one to the other and that makes it doubly hard for a high school pupil to ge two years of college work and then pass smoothly into college work. We demand an intensive course preparatory to a professional education which cannot be given in the professional or technical school, but in making this demand we place our students at a disadvantage because of this attitude on the part of the universities who do not wish to modify their curriculum to suit these two-year men. Until they accept it as a part of their duty to correlate their entrance requirements with the generally accepted and accredited high schools, there is going to be great difficulty in advancing men from the high school into the college to meet the requirements Dr. MacLean has mentioned.

DR. RANDOLPH WINSLOW, University of Maryland: I wish to endorse the suggestion that any man who has been unfortunate enough not to be able to secure the necessary collegiate training should have the right to get a medical education if he is capable.

DR. H. D. ARNOLD, Boston: I think we may admit that the strict regulations which we have tried to place about our examinations are due to the fact that we are not living up to our present standards. What we need more than anything else is a minimum that will be lived up to.

DR. J. S. FERGUSON, Cornell University: It seems to me anomalous that the same effort that tends to elevate the degree of M.D. should lower the degree of A.B. If we would endeavor to exercise our influence with the colleges not to do that, we would be able to secure preparatory medical courses in the non-state-supported institutions.

DR. ARTHUR DEAN BEVAN, Rush Medical College: Modern medicine demands a certain preliminary training. It demands that a man have a well-rounded secondary school education and a training in chemistry, physics and biology. The colleges which do not require that are doing poor, inefficient work in the light of the demands of modern medicine. Medical education also demands one year of practical training in a hospital where the student is part of the hospital machinery for the care of patients.

Administration of Entrance Requirements

DR. B. D. HARISON, Michigan State Board of Registration in Medicine: The proper method of administering requirements is by the board itself, covering credentials and credits, and in the event of an applicant not having the required qualification, he should be referred to a board of preliminary examiners, consisting of not less than four high school principals or superintendents for regular examination on the standard set by the board, covering a high school credential and its symmetrical features. This board reports its findings to the medical board. A properly constituted board of this kind will, in my experience, refuse the proper certificate to at least 75 per cent. of the applicants. This is not only an honest administration, but a practical one.

(*To be continued*)

AMERICAN CONFEDERATION OF RECIPROCATING EXAMINING AND LICENSING MEDICAL BOARDS

Ninth Annual Meeting, held in Chicago, March 3, 1911

The President, DR. WILLIAM A. SPURGEON, Muncie, Ind., in the Chair

Officers Elected

Dr. Spurgeon was reelected president and Dr. B. D. Harison, secretary; Dr. A. W. Alvord, Battle Creek, Mich., was elected vice-president.

Report of Secretary

Dr. Harison reported that the following states (fourteen) are now in membership in the confederation: Georgia, Indiana, Iowa, Kansas, Maryland, Michigan, Nebraska, Nevada, North Dakota, Ohio, Oklahoma, Utah, West Virginia and Wisconsin.

The following states (nineteen) reciprocate on the basis of the qualifications adopted by the confederation, but are not in membership: Arkansas, Colorado, Delaware, District of Columbia, Illinois, Kentucky, Louisiana, Maine, Minnesota, Missouri, New Hampshire, New Jersey, New York, South Carolina, Tennessee, Texas, Vermont, Virginia and Wyoming.

From Jan. 1, 1910, to Jan. 1, 1911, 1,000 reciprocal registrations were made by twenty-five states, 894 on the basis of Qualification No. 1 and 106 on the basis of Qualification No. 2.

Report of Committee on College Inspection

Dr. Spurgeon, chairman, reported that the following constituted the committee on college inspection: W. A. Spurgeon, Indiana, chairman; A. W. Alvord, Michigan; H. A. Barbee, West Virginia; H. H. Baxter, Ohio; I. H. Goss, Georgia; E. A. Carr, Nebraska; J. V. Stevens, Wisconsin. It was recommended that any inspection made be in the company of some representative of the state board of the state wherein the inspection was made, since each state board was the court of last resort regarding these matters in its own state. It was resolved also that the examiner should cooperate with the Council on Medical Education of the American Medical Association and with the Association of American Medical Colleges. The standard of rating was to be the standard adopted by the confederation in 1908.

Dr. J. V. Stevens, secretary, reported that it was decided to ask the colleges to pay the expense of the inspection. The work cannot be completed before the next meeting of the confederation, and no information can be given out now.

Report of Committee on Amalgamation with the National Confederation

Dr. Harison, chairman, reported that a conference was held with a committee from the national confederation in June, 1910, but that no definite action was taken at that time. It was considered desirable that the two confederations unite, but the basis for such a merger could not be made mutually agreeable then. The following communication bearing on this subject was then presented:

CHICAGO, March 2, 1911.

At the call of Dr. W. P. Harlow, dean of the School of Medicine of the University of Colorado, and president of the Association of American Medical Colleges, the following persons met in an informal conference for the purpose of discussing how a union of the two confederations of state examining and licensing boards might be effected:

Dr. Arthur Dean Bevan and Dr. N. P. Colwell, chairman and secretary, respectively, of the Council on Medical Education of the American Medical Association; Dr. Charles A. Tuttle and Dr. George H. Matson, president and secretary, respectively, of the National Confederation of State Medical Examining and Licensing Boards; Dr. William A. Spurgeon and Dr. B. D. Harison, president and secretary, respectively, of the American Confederation of Reciprocating Examining and Licensing Medical Boards; Mr. Abraham Flexner of the Carnegie Foundation for the Advancement of Teaching; Dr. William P. Harlow and Dr. Fred C. Zapffe, president and secretary, respectively, of the Association of American Medical Colleges.

On motion of Dr. Bevan, Dr. Harlow was made chairman and Dr. Zapffe secretary of the conference.

On motion of Dr. Bevan, seconded by Dr. Harison, it was voted that it be the sense of the conference that it is desirable that there be in this country one strong organization of state examining and licensing boards.

On motion of Dr. Matson, seconded by Dr. Colwell, it was voted that the name of such an organization might well be the National Federation of State Medical Boards.

On motion of Dr. Harison, seconded by Dr. Matson, it was voted that the membership of such an organization should consist of members, fellows and associates; that state boards only to be entitled to membership, with power to vote; ex-state board members to be elected to fellowship, without vote, and physicians, not members of an examining or licensing board, who are interested in medical education and state licensure, to be elected to associate membership (without vote) by a two-thirds vote of the members present at any meeting. Only fellows are to be exempt from the payment of dues.

WILLIAM P. HARLOW, Chairman.
FRED C. ZAPFFE, Secretary.

By a resolution presented by Dr. A. W. Alvord, it was voted that the president and secretary of the confederation with three others selected by the president constitute a committee to meet with a similar committee representing the national confederation for the purpose of effecting an amalgamation of the two organizations. The committee appointed consists of Drs. A. W. Alvord, Michigan; E. A. Carr, Nebraska; H. H. Baxter, Ohio; William A. Spurgeon, Indiana, and B. D. Harison, Michigan.

By another resolution presented by Dr. Spurgeon, it was voted that specific education provisions in a medical practice act tend to weaken the law and to limit the educational standards in the state; that the confederation recommends the conferring of discretionary powers on the board of registration in the matter of educational control, and that the law should provide that the board make, establish and require such rules and regulations for the control of medical colleges as shall keep the educational standard of the state at least on a par with the average standard of surrounding states.

Entrance Requirements

DR. B. D. MYERS, University of Indiana, discussed the present requirements for admission to medical colleges demanded by fifteen medical colleges beyond the high school graduation, and presented some data compiled by the secretary of the Council on Medical Education of the American Medical Association, showing the lack of uniformity in these requirements. Six schools demand sixty hours of work, or two years of college work, in addition to the four years of high school work; eight demand from sixty-one to sixty-nine hours, and one school demands as high as eighty-two hours. Among the required subjects are physics (twelve colleges); botany and zoology or either (thirteen colleges); vertebrate anatomy (four); embryology (two); osteology (one); English (eleven); modern language (twelve); chemistry (fourteen); psychology (seven); Latin (one); economics, sociology, history and political science (eight); mathematics (five); hygiene (one); military drill (one); electives offered (seven). Four colleges offer electives to the extent of twenty-one, twenty-four, thirty-two and thirty-three hours, respectively, out of a total of sixty hours.

POSTGRADUATE COURSE FOR COUNTY SOCIETIES

DR. JOHN H. BLACKBURN, DIRECTOR
BOWLING GREEN, KENTUCKY

[The Director will be glad to furnish further information and literature to any county society desiring to take up the course.]

Eighth Month—Fourth Weekly Meeting

PUERPERAL INJURIES

INJURIES OF THE PELVIC FLOOR: Varieties: 1. Superficial median tears. 2. Deep median tears, involving sphincter. 3. Lateral tears involving sulci. Pathology and diagnosis of each.

TREATMENT OF PERINEAL LACERATIONS: Indications and contra-indications for primary and for secondary operations.

Technic of repair (a) of deep (complete) laceration, (b) of laceration involving sulci.

After-treatment of operations for repair of perineal lacerations.

INJURIES OF CERVIX UTERI

VARIETIES: Bilateral, unilateral, stellate.

SYMPTOMS: Backache, bearing-down feeling, headache, leukorrhea, menstrual disorders, sterility, abortion.

Indications and contra-indications for repair of laceration of cervix.

Preliminary and preparatory treatment.

Technic of trachelorrhaphy, of amputation of cervix.

Monthly Meeting

The Differential Diagnosis of Ovarian Cysts.

The Non-Surgical Treatment of Retrodisplacements of the Uterus.

The Symptoms and Diagnosis of Fibromyomata of the Uterus.

The Prophylaxis and Treatment of Puerperal Injuries of Cervix and Perineum.

Book Notices

AN INTRODUCTION TO VERTEBRATE EMBRYOLOGY. Based on the Study of the Frog, Chick and Mammal. By Albert Moore Reese, Ph.D. (Johns Hopkins), Professor of Zoology in West Virginia University. Second Edition. Cloth. Price, $1.50 net. Pp. 340, with 118 illustrations. New York: G. P. Putnam's Sons, 1909.

Since the development of man and other mammals is, in most particulars, strikingly like that of the chick, a study of the latter is helpful. In this book the author presents an outline of the main facts of the embryology of the chick—also of the frog—keeping in mind particularly the needs of the medical student. The description considers periods of development: all the changes that take place during a certain period are described in one section; instead of describing at one time the complete development of any one organ. This method is not only pedagogically correct but enables the student to grasp facts better and more quickly. Theoretical discussions are carefully avoided. The author has added a chapter of forty pages on "The Development of the Mammal," in which are pointed out the main differences between the embryologic processes of the chick and those of man

WE YOUNG MEN. The Sexual Problem of an Educated Young Man Before Marriage: Purity, Strength and Love. By Hans Wegener. Introduction by Sylvanus Stall. Paper. Price, 70 cents. Pp. 204. Philadelphia: Vir Publishing Co., 1911.

It was a most commendable piece of work to translate this German book, thereby making it available for young men who read English. As the advertisements state, it is a square talk face to face. It is a delicate but vigorous presentation of clean living. Some will object to the frank way in which the author takes for granted that some young men seriously consider the breaking of various moral laws concerning sexual indulgence. For this very reason, however, the book will have greater weight with this class of men than the numerous books already on the market which preach to young men. We do not mean to suggest that this book is not on a high plane, for it is full of noble and lofty appeal to the best that is in a man; but it meets young men on their own level, and it has the valuable quality of convincing the reader that the author has been in pretty close touch with these problems. The book is a good one to succeed "The Boy's Venereal Peril," being intended for youths who are a little more mature.

RADIUM: ITS PHYSICS AND THERAPEUTICS. By Dawson Turner, B.A., M.D., F.R.C.P., Edin., Lecturer on Medical Physics, Surgeons' Hall, Edinburgh. Cloth. Price, $1.75 net. Pp. 86, with 27 illustrations. New York: William Wood & Co., 1911.

This is a little octavo book of only 86 pages, hardly larger than some of the elaborate papers on radium therapy, but it satisfactorily covers the subject. The essential facts in the physics and the principles of the therapeutic application of radium are clearly and simply given, without any of the complexity usually found in articles on the subject, which indicates more than anything else a hazy knowledge on the part of the writer. It may be specially noted that Turner considers carefully the histologic changes produced by radium in both healthy and diseased tissues—a topic which would seem to be of obvious importance in any consideration of radium therapy, but one, so far as we know, which no other book on the subject has given in detail. The book is a fine example of how simply and briefly a rather muddled subject can be stated by one who understands it and who has the ability to think clearly and distinguish essentials from trivialities.

PRACTICAL PHYSIOLOGY. Edited by M. S. Pembrey. By Various Contributors. Third Edition. Coth. Price, $4 net. Pp. 480, with 253 illustrations. New York: Longmans, Green & Co., 1910.

In this book not only are the facts of the physiology of the human organism taught according to the latest deductions and conclusions, but each is demonstrated by an abundance of experiments, both elementary and more advanced, and the practical application made with reference both to normal and pathologic function in the practice of medicine. Physiologic chemistry, in both its elementary and its more advanced aspects, is clearly treated, Part IV being devoted to the latter. The impression conveyed in an examination is that this book constitutes, not a mere enumeration of the facts of physiology, but a helpful, practical work on physiology, from the standpoint of the student or the practitioner.

Medicolegal

Expert Evidence Without Statement of Facts and Right to Show Latter

The Court of Appeals of New York holds, in the homicide case of People vs. Faber (92 N. E. R. 674), that there was no error in allowing physicians to express their opinions in regard to the sanity of the defendant without previously stating in detail the observations on which the opinions were based.

The court says that in the early history of the courts of England mere opinion evidence was wholly rejected. The admission of opinions as evidence by persons specially qualified by skill and experience to speak as experts has been a matter of development both in England and in this country. The history of the admission of such evidence with illustrations from decisions of the courts is given by Wigmore in his exhaustive work on Evidence, and in connection therewith he refers to the practice of admitting opinion evidence by experts based on observation, and concludes that evidence by experts of conceded skill and experience may be received when based on the observation of the witness without in the first instance necessarily requiring that the facts observed be stated to the court and jury. There is a great difference in the decisions of the courts of the states on this subject, but this court is in accord with the conclusions reached by Mr. Wigmore.

In common practice in the courts a physician who has examined a patient is allowed to testify directly as to the disease from which the patient is suffering. There seems to be no good reason for requiring a physician to specify in detail his observations before expressing an opinion as to the sanity or insanity of a person examined by him any more than he should be required to recount such observations in advance of expressing an opinion as to whether a person had typhoid fever or was suffering from an epileptic fit. It is competent, however, for a person offering an expert as a witness, for the purpose of showing the strength of the opinion which he is about to express, to specify in detail the observations on which the opinion is based. It is also, of course, competent for the opposite party on cross-examination to call for the observations, and probe the underlying facts to the fullest extent for the purpose of thus affecting, so far as possible, the strength of the opinion expressed or to form a basis on which other experts may be asked to contradict or explain the opinion first expressed.

Weight to be Given Expert Testimony

The Supreme Court of Georgia holds, in Rouse vs. State (69 S. E. R. 180) that, there being no statute prescribing the weight which shall be given to the testimony of an expert, what consideration such evidence is entitled to is a question solely for the jury. Under this principle, it was error to charge the jury that, "When the experience, honesty, and impartiality of the expert is undoubted by the jury, his testimony is entitled to great weight. It is not, however, so authoritative that the jury is bound to be governed by it. It is advisory merely, and such testimony is intended to assist you in coming to a correct conclusion." Moreover, such charge was error despite the fact that witnesses both for the state and for the accused testified on the trial of the case.

Crime Not Affected by Lack of Skill in Treatment of Wounds

The Supreme Court of Georgia holds, on the appeal of Perdue vs. State (69 S. E. R. 184), a homicide case, that, where one inflicts on another a wound with a weapon likely to produce death, and the person wounded actually dies in consequence of the wound, the quality of the act of the slayer cannot be affected by a lack of skill and care on the part of those who treat or attempt to treat the wounds and administer remedies therefor.

Current Medical Literature

[In the abstract of the case report of "Heroin Poisoning," made from the *Kentucky Medical Journal*, February 15, in THE JOURNAL, March 11, 1911, p. 777, the dose should have been 1/12 of a grain of heroin, instead of ½.]

·AMERICAN

Titles marked with an asterisk (*) are abstracted below.

Boston Medical and Surgical Journal

March 9

1 *Dependence of Intestinal Indigestion on Gastric Disturbances. A. E. Austin, New York.
2 *The Possible Effect of Salvarsan on the Auditory Labyrinth. G. Alexander, Vienna.
3 Treatment of Fistula in Ano. T. C. Hill, Boston.

1. **Dependence of Intestinal Indigestion on Gastric Disturbances.**—Austin concludes that diarrhea does not always accompany an achylia nor a hypochlorhydria, nor can one, from the presence of connective tissue in the stool, always deduce the state of the gastric juice. Furthermore, while hyperchlorhydria is usually accompanied by constipation, there may be diarrhea, or the bowels may be regular, while with gastric myasthenia constipation is the rule, as it is in hypersecretion. A functional chronic catarrh of the small intestine may exist associated with any of these gastric conditions, with excessive or no free hydrochloric acid, and with increased or impaired motility, so that one can only say that improperly prepared food is poured into the small intestine which, either on account of this extra burden or on account of some antecedent inflammatory disturbance, undergoes a functional impairment that usually manifests itself by the increased motility.

2. **Effect of Salvarsan on the Auditory Labyrinth.**—Personal observations lead Alexander to recommend caution in the use of salvarsan in cases of acute syphilis of the auditory nerve. Especially is caution in the use of the remedy recommended in the presence of acute or chronic disease of the auditory nerve in cases of recent syphilis, as here it is to be feared that the ear symptoms will be made worse. It appears to make no difference whether the disease of the auditory nerve is of itself of syphilitic origin or not. An unfavorable influence is also to be feared in cases of acute syphilitic affection of the auditory nerve in old cases of syphilis or latent chronic syphilis. In cases of hereditary syphilis, in the presence of acute manifestations of trouble with the auditory nerve, it is advisable to wait before giving the injection. On the other hand, there are a large number of cases of ear disease in which the dangers from the injection cannot be considered as dependent on it. Here belong the cases of chronic syphilitic affection of the auditory nerve with slight diminution of hearing power and considerable tinnitus, as well as the cases of chronic labyrinth dizziness. Alexander found that the injection has a good effect in cases of chronic labyrinth disease in chronic syphilis.

An Introduction to Vertebrate Embryology. Based on the Study of the Frog, Chick and Mammal. By Albert Moore Reese, Ph.D. (Johns Hopkins), Professor of Zoology in West Virginia University. Second Edition. Cloth. Price, $1.50 net. Pp. 340, with 118 illustrations. New York: G. P. Putnam's Sons, 1909.

Since the development of man and other mammals is, in most particulars, strikingly like that of the chick, a study of the latter is helpful. In this book the author presents an outline of the main facts of the embryology of the chick—also of the frog—keeping in mind particularly the needs of the medical student. The description considers periods of development: all the changes that take place during a certain period are described in one section; instead of describing at one time the complete development of any one organ. This method is not only pedagogically correct but enables the student to grasp facts better and more quickly. Theoretical discussions are carefully avoided. The author has added a chapter of forty pages on "The Development of the Mammal," in which are pointed out the main differences between the embryologic processes of the chick and those of man

We Young Men. The Sexual Problem of an Educated Young Man Before Marriage: Purity, Strength and Love. By Hans Wegener. Introduction by Sylvanus Stall. Paper. Price, 70 cents. Pp. 204. Philadelphia: Vir Publishing Co., 1911.

It was a most commendable piece of work to translate this German book, thereby making it available for young men who read English. As the advertisements state, it is a square talk face to face. It is a delicate but vigorous presentation of clean living. Some will object to the frank way in which the author takes for granted that some young men seriously consider the breaking of various moral laws concerning sexual indulgence. For this very reason, however, the book will have greater weight with this class of men than the numerous books already on the market which preach to young men. We do not mean to suggest that this book is not on a high plane, for it is full of noble and lofty appeal to the best that is in a man; but it meets young men on their own level, and it has the valuable quality of convincing the reader that the author has been in pretty close touch with these problems. The book is a good one to succeed "The Boy's Venereal Peril," being intended for youths who are a little more mature.

Radium: Its Physics and Therapeutics. By Dawson Turner, B.A., M.D., F.R.C.P., Edin., Lecturer on Medical Physics, Surgeons' Hall, Edinburgh. Cloth. Price, $1.75 net. Pp. 86, with 27 illustrations. New York: William Wood & Co., 1911.

This is a little octavo book of only 86 pages, hardly larger than some of the elaborate papers on radium therapy, but it satisfactorily covers the subject. The essential facts in the physics and the principles of the therapeutic application of radium are clearly and simply given, without any of the complexity usually found in articles on the subject, which indicates more than anything else a hazy knowledge on the part of the writer. It may be specially noted that Turner considers carefully the histologic changes produced by radium in both healthy and diseased tissues—a topic which would seem to be of obvious importance in any consideration of radium therapy, but one, so far as we know, which no other book on the subject has given in detail. The book is a fine example of how simply and briefly a rather muddled subject can be stated by one who understands it and who has the ability to think clearly and distinguish essentials from trivialities.

Practical Physiology. Edited by M. S. Pembrey. By Various Contributors. Third Edition. Coth. Price, $4 net. Pp. 480, with 255 illustrations. New York: Longmans, Green & Co., 1910.

In this book not only are the facts of the physiology of the human organism taught according to the latest deductions and conclusions, but each is demonstrated by an abundance of experiments, both elementary and more advanced, and the practical application made with reference both to normal and pathologic function in the practice of medicine. Physiologic chemistry, in both its elementary and its more advanced aspects, is clearly treated, Part IV being devoted to the latter. The impression conveyed in an examination is that this book constitutes, not a mere enumeration of the facts of physiology, but a helpful, practical work on physiology, from the standpoint of the student or the practitioner.

Medicolegal

Expert Evidence Without Statement of Facts and Right to Show Latter

The Court of Appeals of New York holds, in the homicide case of People vs. Faber (92 N. E. R. 674), that there was no error in allowing physicians to express their opinions in regard to the sanity of the defendant without previously stating in detail the observations on which the opinions were based.

The court says that in the early history of the courts of England mere opinion evidence was wholly rejected. The admission of opinions as evidence by persons specially qualified by skill and experience to speak as experts has been a matter of development both in England and in this country. The history of the admission of such evidence with illustrations from decisions of the courts is given by Wigmore in his exhaustive work on Evidence, and in connection therewith he refers to the practice of admitting opinion evidence by experts based on observation, and concludes that evidence by experts of conceded skill and experience may be received when based on the observation of the witness without in the first instance necessarily requiring that the facts observed be stated to the court and jury. There is a great difference in the decisions of the courts of the states on this subject, but this court is in accord with the conclusions reached by Mr. Wigmore.

In common practice in the courts a physician who has examined a patient is allowed to testify directly as to the disease from which the patient is suffering. There seems to be no good reason for requiring a physician to specify in detail his observations before expressing an opinion as to the sanity or insanity of a person examined by him any more than he should be required to recount such observations in advance of expressing an opinion as to whether a person had typhoid fever or was suffering from an epileptic fit. It is competent, however, for a person offering an expert as a witness, for the purpose of showing the strength of the opinion which he is about to express, to specify in detail the observations on which the opinion is based. It is also, of course, competent for the opposite party on cross-examination to call for the observations, and probe the underlying facts to the fullest extent for the purpose of thus affecting, so far as possible, the strength of the opinion expressed or to form a basis on which other experts may be asked to contradict or explain the opinion first expressed.

Weight to be Given Expert Testimony

The Supreme Court of Georgia holds, in Rouse vs. State (69 S. E. R. 180) that, there being no statute prescribing the weight which shall be given to the testimony of an expert, what consideration such evidence is entitled to is a question solely for the jury. Under this principle, it was error to charge the jury that, "When the experience, honesty, and impartiality of the expert is undoubted by the jury, his testimony is entitled to great weight. It is not, however, so authoritative that the jury is bound to be governed by it. It is advisory merely, and such testimony is *intended* to assist you in coming to a correct conclusion." Moreover, such charge was error despite the fact that witnesses both for the state and for the accused testified on the trial of the case.

Crime Not Affected by Lack of Skill in Treatment of Wounds

The Supreme Court of Georgia holds, on the appeal of Perdue vs. State (69 S. E. R. 181), a homicide case, that, where one inflicts on another a wound with a *weapon likely* to produce death, and the person wounded actually dies in consequence of the wound, the quality of the act of the slayer cannot be affected by a lack of skill and care on the part of those who treat or attempt to treat the wounds and administer remedies therefor.

Current Medical Literature

[In the abstract of the case report of "Heroin Poisoning," made from the *Kentucky Medical Journal*, February 15, in THE JOURNAL, March 11, 1911, p. 777, the dose should have been 1/12 of a grain of heroin, instead of ½.]

Boston Medical and Surgical Journal

March 9

1 *Dependence of Intestinal Indigestion on Gastric Disturbances. A. E. Austin, New York.
2 *The Possible Effect of Salvarsan on the Auditory Labyrinth. G. Alexander, Vienna.
3 Treatment of Fistula in Ano. T. C. Hill, Boston.

1. **Dependence of Intestinal Indigestion on Gastric Disturbances.**—Austin concludes that diarrhea does not always accompany an achylia nor a hypochlorhydria, nor can one, from the presence of connective tissue in the stool, always deduce the state of the gastric juice. Furthermore, while hyperchlorhydria is usually accompanied by constipation, there may be diarrhea, or the bowels may be regular, while with gastric myasthenia constipation is the rule, as it is in hypersecretion. A functional chronic catarrh of the small intestine may exist associated with any of these gastric conditions, with excessive or no free hydrochloric acid, and with increased or impaired motility, so that one can only say that improperly prepared food is poured into the small intestine which, either on account of this extra burden or on account of some antecedent inflammatory disturbance, undergoes a functional impairment that usually manifests itself by the increased motility.

2. **Effect of Salvarsan on the Auditory Labyrinth.**—Personal observations lead Alexander to recommend caution in the use of salvarsan in cases of acute syphilis of the auditory nerve. Especially is caution in the use of the remedy recommended in the presence of acute or chronic disease of the auditory nerve in cases of recent syphilis, as here it is to be feared that the ear symptoms will be made worse. It appears to make no difference whether the disease of the auditory nerve is of itself of syphilitic origin or not. An unfavorable influence is also to be feared in cases of acute syphilitic affection of the auditory nerve in old cases of syphilis or latent chronic syphilis. In cases of hereditary syphilis, in the presence of acute manifestations of trouble with the auditory nerve, it is advisable to wait before giving the injection. On the other hand, there are a large number of cases of ear disease in which the dangers from the injection cannot be considered as dependent on it. Here belong the cases of chronic syphilitic affection of the auditory nerve with slight diminution of hearing power and considerable tinnitus, as well as the cases of chronic labyrinth dizziness. Alexander found that the injection has a good effect in cases of chronic labyrinth disease in chronic syphilis.

4. **Pellagra.**—While holding that we should follow with attention the new theories and the result of the researches on the *etiology* of pellagra conducted through new lines far apart from the theory well established by Lombroso, based on the use of Indian corn, and to its late modifications, Caccini urges caution in casting aside the result of careful inves-

tigations (based on well-established data) to embrace in our enthusiasm mere suggestions of young observers. Sambon's and Alessandrini's theories, that would tend to make of pellagra a disease of protozoal or parasitic nature, respectively, he would consider as mere suggestions, rather than theories or even intuitions of a new theory. As to the development in the United States, pellagra has been present in the United States in sporadic cases for a long time, but it has lately been diffused everywhere in the different states, assuming an epidemic character. The disease assumes a more acute course in contrast to its characteristics in Europe, and particularly in Italy, where, although very common, it has always the character of chronicity and the erythema never assumes the severe character which it does in the United States.

5. **New Variant for Hernioplasty.**—The procedure employed by Gerster in a case of large ventral hernia, without adhesions, is described as follows: An oval portion of the central area was excised as far as it was found to be thin and anemic, then the hernial aperture in the parietes was dissected out until the aponeuroses of the rectus and the oblique came into view under the laterally detached skin-flaps. After this, seven sutures of quadruple stout chromic catgut were used to approximate and keep in contact the edge of the rectus and the musculo-aponeurotic line of the oblique muscles, the sutures passing through the sheath of the rectus. Above this, a second row of single catgut sutures was superimposed, widening the surfaces of contact. Thus there were formed two redundant, cockscomb-shaped flaps of aponeurosis and stout cicatricial material, that met with their peritoneal faces above the stout sutures. Of these the external one was twice scored, thus scalloped into three digits, the inner one receiving three corresponding stabs, which would form three slits comfortably admitting the three fingerlike processes. Each process having been passed through its corresponding fenestrum was sutured at its extreme end to the underlying fascia of the rectus; the inner square edge of the fenestrated flap being likwise sutured to the aponeurosis of the underlying external oblique muscle by six or seven stitches. Over all this the skin was brought together and sewed with interrupted fine silk sutures.

6. **Salicylates in Rheumatism.**—That a salicylate solution could be injected hypodermically without discomfort to the patient, and that a sufficiently large injection of salicylic acid or sodium salicylate would destroy the vitality and inhibit the pathogenic action of rheumatic organisms in the human body in a few hours without causing symptoms of salicylic poisoning, is the belief Seibert holds as the result of observation. In acute rheumatic infection of joints, heart, pericardium, pleura and central nervous system (chorea), he injected 10 c.c. of a 20 per cent. sterilized solution of fresh sodium salicylate to 100 pounds of body weight, fifteen minutes after an appropriate cocain solution had been injected under the same spot. If the injections are made earlier than this, he found that the solution caused pain. This dose is repeated every twelve hours. In severe cases, with many localizations of the rheumatic process, he says that the dose *may* be increased to 15 c.c. of the solution to 100 pounds of body weight. He considers it essential to the success of this treatment that the above doses be used. Smaller doses will be without effect. The effect may be noticed within three hours after the first injection. Joint stiffness, pain, fever and pulse-rate diminish and the general feeling of the patient improves. If the injections are continued regularly, every twelve hours, the improvement also continues; if they are omitted for twenty-four hours in severe cases, the symptoms will grow worse; but in milder cases the improvement may continue, proving that a sufficient amount of the salicylate had already been injected to destroy all rheumatic organisms in that case.

In chronic cases 10 c.c. to 100 pounds of body weight of the following oily solution are injected every twenty-four hours: Acid salicylici, 10 grams (2½ drams); olei sesami, 80 grams (20 drams); alcohol, pure, and gum camphor, 5 grams (1¼ drams) each. This mixture is sterilized before the alcohol is added, but must not be exposed to the air, as the alcohol will evaporate and the salicylic-acid crystals will precipitate. The effect of the injection in chronic cases is noticed sooner when multiple localizations of the rheumatic process are present than when but one joint is affected. In the former, pain and stiffness usually improve after the first, in the latter, after the third injection. The addition of camphor (from 5 to 20 per cent.) has been found beneficial in stimulating the heart, especially in pericarditic and endocarditic cases. The weaker the heart, the more camphor may be given in the oil. The entire absence of all the toxic symptoms which are sometimes seen when salicylates are given by mouth, is said to be one of the pleasantest features of this method of treatment. The technic of injection is described fully.

9. **Artificial Muscles in Infantile Paralysis.**—Artificial rubber muscles are made to take the place of paralyzed or weak muscles by Meisenbach. For the construction of artificial muscles an ordinary rubber dam is used. The method is chiefly applicable to the ankle, the knee, the wrist and shoulder joints. By the use of artificial muscles the lost power may be supplied temporarily until the paralyzed muscles have recovered, and contractures of opposing groups may be prevented. The rubber over the affected muscles causes a local stimulation which is noted by active hyperemia and perspiration of the skin beneath the artificial muscle. Its use does not immobilize the joint, nor does it interfere with other prescribed treatment, namely, passive motion, massage, or electrical contractions. Its efficiency is continuous and its simplicity does not interfere with the clothing or the bathing. It is not intended to be used in advanced cases after the contractions have taken place.

18. **Cirrhosis of the Liver.**—According to Mallory, at least five different types of lesions may terminate in cirrhosis (sclerosis) of the liver; one is acute, the other four more or less chronic in character. Toxic cirrhosis (following extensive central necrosis) demonstrates clearly the following three facts: 1. When all the liver cells of a lobule are destroyed the bile ducts grow out a certain distance toward the hepatic vein, but do not produce liver cells. 2. Liver cells regenerate only from liver cells, never from bile duct epithelium. 3. Fibroblasts (connective tissue cells) do not proliferate when liver cells alone are destroyed. The other four types of lesions terminating in cirrhosis show that fibroblasts multiply (regenerate) only when fibroblasts themselves have been injured or destroyed and thus lead to increase of the connective tissue. The so-called alcoholic type of cirrhosis is characterized by a peculiar hyaline degeneration of the cytoplasm of the liver cells preceding necrosis. In this same type of cirrhosis the contraction of the connective tissue frequently compresses groups of liver cells so that they may resemble bile ducts; in these compressed liver cells it is often possible to demonstrate large fat vacuoles or hyaline material due to degeneration in the cytoplasm, neither of which occurs in true bile duct epithelium. In toxic cirrhosis the connective tissue

thickens from contraction, but does not increase in amount because the fibroblasts have not been injured. In infectious cirrhosis the fibroblasts are destroyed along with the liver-cells; hence there is active regeneration and much production of connective tissue. In syphilitic infection of the liver the primary injury is done to fibroblasts; in consequence they proliferate (regenerate), often in excess; the contraction later of the collagen fibrils produced by them results in compression and more or less atrophy of the included liver cells. In pigment and alcoholic cirrhosis the proliferation of the fibroblasts is apparently due to injury caused mechanically by cells of exudate origin stretching the connective tissue; the reaction is similar to that produced in the lungs and peribronchial lymph nodes by endothelial leukocytes filled with carbon packing themselves in the finer lymph spaces.

19. **Typhoid Spine.**—These two cases are reported fully by McCrae. In the first case symptoms of typhoid spine were present in March, 1909, four months after the recovery from typhoid, and again in April. One point of interest is the occurrence of a relapse or second attack between five and six months after the original attack. Whether this should be termed a relapse or a second attack, McCrae found it difficult to decide, for there is no period which can be set as a dividing line between a relapse and a second attack. The case here reported is much like one previously described by McCrae, in which the original attack began on June 2, the patient being convalescent in March when the symptoms of typhoid spine appeared. He was admitted to the hospital on July 4 of the same year for the spinal symptoms, and a week later the second attack (or relapse) of typhoid began. In both of these cases there was an interval of months between the attacks, in which the symptoms of spondylitis appeared. One explanation of the cause of typhoid spondylitis is that there are local lesions in the bone in which typhoid bacilli are present. McCrae was tempted to suggest that this focus may have been the source of the second infection in these cases. However, our knowledge of what determines relapses is not very satisfactory and it would be easier to regard the second febrile attack in these two cases as a second attack rather than as a relapse. Besides, the retention of typhoid bacilli in the body after recovery from an attack of typhoid is so common (e. g. in the gall-bladder) that we should not attach too much importance to such a source of reinfection.

The second case is unusual in several particulars. In the first place it shows that typhoid spondylitis may occur without any severe pain. The symptom of pain has been regarded as the most essential one in "typhoid spine" and it is very evident in this case that but for the radiogram the diagnosis of spondylitis could not have been made. In this event the condition in the popliteal nerve would have been regarded as a posttyphoid neuritis and the causal influence of the local process in the spine would not have been recognized. The involvement of the nerve root on the opposite side to that on which the deposit of bone occurred is seen not infrequently in cases of spondylitis. McCrae thinks it may be regarded as an established fact that "typhoid spine" is a spondylitis or a perispondylitis with definite local changes which may lead to the formation of new bone and so result in more or less fixation of the spine. Judging from spondylitis generally, this permanent change is less likely to occur if the proper treatment is instituted early. Many cases of spondylitis clear without permanent changes.

20. **Erythema Multiforme Iris.**—The authors regard it as certain that the patient had typhoid on two occasions, the second attack occurring within a week after recovery from the first. During the height of the first attack he had the following symptoms characteristic of the erythemas: annular and macular skin lesions, and swelling and redness of the carpophalangeal joints. During the height of his relapse he suffered from edema of the upper lip (giant urticaria), erythema at points of pressure and hemoptysis. The fact that these lesions occurred only when the infection was young and active, the authors think would seem to indicate that the typhoid toxemia was responsible for them.

21. **Acute Tuberculous Endaortitis.**—The case reported by Woolley is the eleventh of acute tuberculous endaortitis. The aortic tubercles were the result not of extension, but of mestastasis from chronic lesions in the kidney. The general miliary tuberculosis that co-existed with the chronic tuberculosis, was not the result of dissemination of organisms from the aortic lesions. The bacilli in the aortic lesions showed bizarre forms with a tendency to branching.

22. **Extensive Thiersch Skin Graft.**—The case reported by Gatch has two points of chief interest: the large size of the area grafted, and the demonstration, by repeated trials, that only homografts would take in this patient. He was admitted to hospital on Nov. 21, 1909, for flame burns of the back and of the left forearm and hand which he had received fourteen hours before admission. The burn of the back was of the second degree, the others of the first. The area of this burn was 430 square inches. As the total area of the patient's body is about 2,800 square inches, the burn occupied between a sixth and a seventh of his entire cutaneous area. The patient recovered from the immediate effects of the injury rapidly and with little general systemic disturbance. While the sloughs were separating, the wounds were dressed with a single layer of dry gauze, which was left in place for periods of a week or more, and then changed after giving the patient a prolonged warm bath. Absorbent dressings, changed as often as necessary, were placed over the gauze. This dressing proved very clean and comfortable. In less than two weeks the burned surface was covered with healthy granulations. Now followed a long series of attempts to cover the large raw area with skin. None of the isografts applied to this patient lived, though applied under the same conditions as the homografts—practically all of which did take.

35. **Estimation of Creatinin.**—The greatest defect of this method, in Taylor's opinion, lies in the absence of a standard light. If the Folin method is to attain to that general usefulness and reliability to which its intrinsic qualities entitle it, he says that a light must be found, standard in quality and intensity. Under ideal conditions, the method will enable one to estimate 10 milligrams of creatinin with an accuracy of plus or minus 0.1 milligram. Under desirable conditions of concentration, urinary pigmentation and light, the plus or minus error in the estimation may be at least a milligram. Accurate estimations that can close agreements in the deter-

minations of creatinin are greatly to be desired because in this case we deal with a fundamental metabolism, the full understanding of which we are just beginning to appreciate.

36. **Cutaneous Elimination.**—Taylor presents the results of two metabolic experiments, in which, for the purpose of securing normal data, the attempt was made to secure quantitative determinations of the magnitudes of the cutaneous eliminations of nitrogen, sulphur and phosphorus. He found that in all probability the cutaneous elimination of nitrogen and sulphur is, under constant conditions of work, clothing and temperature, a constant for each individual, and in no wise dependent on the total metabolism of nitrogen and sulphur in the individual. The cutaneous elimination of phosphorus may be said to be *nil.*

69. **What Constitutes a Useful Drug?**—According to Ander a valuable drug is: (1) One that has a definite physiologi action, which is applicable to the relief of a disordered physic logic process; (2) one that by repeated careful clinical obse vations has been found to be followed in the majority o instances by a definite clinical result, care being taken t exclude the influence of accessory circumstances; and (3) on that is used for the purpose of diluting a substance of to great concentration or making palatable an otherwise dis greeable remedy. In accordance with this definition, it ha seemed to Anders that the following, among other agent should be omitted from the official remedies to be found i the U. S. Pharmacopeia: Anthemis, berberis, calamus, cale dula, cassia fistula, chimaphila, chirata, chondrus, cypripediun eriodictyon, eugenol, eupatorium, fluidextractum berberidi fluidextractum calami, fluidextractum chimaphilæ, fluide tractum chiratæ, fluidextractum cypripedii, fluidextractu eriodictyi, fluidextractum eupatorii, fluidextractum frangul fluidextractum geranii, fluidextractum grindeliæ, fluidextractu lappæ, fluidextractum matico, fluidextractum mezerei, fluid extractum rubi, fluidextractum sabinæ, fluidextractum staph sagriæ, fluidextractum tritici, fluidextractum vibur opuli, frangula, geranium, gossypii cortex, gossypium pur ficatum, granatum, grindelia, hedeoma, lappa, manna, ma rubium, mastiche, matico, matricaria, mezereum, myristic oleum betulæ, oleum coriandri, oleum hedeomæ, oleum myris ticæ, pilulæ aloes et mastiches, pimenta, prunum, rubu sabina, safrolum, staphisafria, styrax, tinctura calendula triticum, ulmus, viburnum opulus, xanthoxylum and zea. O the other hand, among unofficial substances that he think might be advantageously added to the U. S. Pharmacopeia ar diacetylmorphin and silver vitellin.

74. **The Galactagogue Action of the Thymus.**—In experi ments on the goat with the glands containing internal secre tions, Ott and Scott found that the thymus and corpus luteu increased the quantity of milk fourfold in five minutes. Th ovary minus corpus luteum had no effect. Infundibulin i still the most powerful galactagogue, increasing the secretio of the milk one hundredfold. The amount of butter fat wa about the same in the augmented secretion by thymus, corpu luteum and infundibulin, though occasionally it was increase Intravenous injection of this body increases the secretion o milk eightfold. The pineal gland, as in previous experiment was rubbed with distilled water and filtered. Normal salin solution, according to Biedl, has been shown to increase th secretion of milk.

81. **Keeping Track of Sponges.**—The plan outlined by Lockwood, briefly, is as follows: In making gauze sponges, have a numeral sewed in colored silk or stamped with indelible ink, of a harmless character, in one corner of each sponge. This renders the figures indestructible in sterilizing the sponge. Have three packages of sponges arranged as follows: first package must contain small sponges, fifteen in all, numerals running from 1 to 15. This completes the first series and the package is to be labeled A 15. The letter A designates the size of sponges contained in the package and the numeral the number it contains. The second series must be a size larger than the first, running from 1 to 10, labeled thus: B 10. Third series is still larger than B, running from 1 to 5, labeled C 5. This package should contain five large sponges or napkins used both for absorbing sponges and viscera towels in abdominal sections. Have sponges made uniformly, each package maintaining a regulation size. The letter on the package indicates the size of sponges contained therein.

When the operation is finished, whether minor or major, count out the sponges by actual notation and if any number be lacking to complete the restored series, never cease searching until the missing number is found. If one or more packages of sponges are used in an operation it is as easy to complete the count in several series as it is in a single series, except that it takes more time. If all the sponges are not used in any one package in a given operation, count out the unused sponges along with the rest to complete the full number in that particular series. While this may seem strenuous and an undue precaution imposed on the surgeon, yet Lockwood believes that such methods would completely avert the possibility of leaving sponges and other materials in the abdominal cavity. A similar numbering plan is suggested for instruments.

94. **The Orthodiagram in Heart Disease.**—After having examined sixty patients, Van Zwaluwenberg and Warren believe that they are justified in the conclusion that an abnormal index is an early evidence of the increase in size of one or more chambers of the heart and may occur before such increase can be demonstrated by other means; that a decrease in the index results from left ventricular hypertrophy and dilatation, and an increase indicates a dilatation of the auricles with or without hypertrophy of the right ventricle. In combinations of these two antagonistic factors the index will depend on the predominance of the one or the other. The wide variation shown in valvular diseases should make the index valuable in the diagnosis of doubtful or combined lesions and they hope that the smaller fluctuations found associated with renal conditions may sometime be of diagnostic and prognostic value.

95. This paper was referred to in an editorial on blackwater fever in THE JOURNAL, Feb. 18, 1911, p. 514.

96. **Meralgia Paresthetica.**—In Miller's case, a circumscribed area of tenderness was located below and slightly outward from the anterior superior spine of the ilium; surrounding this was an ill-defined area of hyperesthesia; no analgesia, anesthesia or thermalgesia. In examining to determine if pressure of the clothing could be responsible for the trouble, it was noted that the lower edge of the corset hooked over the anterior superior spine, pressing into the thigh so that when standing erect it was with difficulty that the finger could be introduced between the corset and the thigh. Following instructions, the patient cut out a portion of the corset over this region. Within a few days relief was marked, and after the lapse of ten days the attacks of pain entirely disappeared, only slight numbness remaining. The woman returned to her work and reported three months later that, except for slight numbness, she considered herself cured. It was suggested that she purchase a new corset of the same style as that previously worn. After wearing this a few days, the pain again recurred, and the patient of her own accord cut out a piece of the corset as before, the pain promptly disappeared and now after the lapse of five months she complains only of slight numbness.

97. **Energy Metabolism of Mother and Child.**—In agreement with results previously obtained on the dog, Carpenter and Murlin find that the curve of total energy production of mother and child suffers no deflection at birth. The extra metabolism of the pregnant woman at the culmination of pregnancy, due in part to the accessory structure as well as to the fetus, is just equaled by the extra metabolism set up in the new-born child by exposure of its body to the outside world, and in the mother by activity of the mammary glands, etc. The energy metabolism, expressed per unit of weight, of the pregnant woman is about 7 per cent. less than that of the same woman newly delivered, and about 4 per cent. more than that of women in complete sexual rest. Expressed per unit of surface ($12.3\sqrt[3]{W^2}$) the energy metabolism of the pregnant woman is specifically higher than that of women in complete sexual rest, probably because of a higher metabolism in the uterus and because of more rapid conduction of heat through the abdominal wall. In the newly delivered and nursing mother the metabolism is likewise higher per unit of surface than that of either the pregnant or normal woman. This is probably due in part to the activity of the mammary glands and in part to the dynamic action of protein liberated by the involution processes. The energy metabolism of the new-born child expressed per unit of weight and found by subtracting the metabolism of mother alone from that of mother and child together, is two and a half times that of the mother. Expressed per unit of surface (same formula) the energy metabolism of the new-born child is not greater than that of the nursing mother, but is higher than that of a woman in complete sexual rest.

98. **Ameboid Activity of Megaloblasts.**—In the study of the blood in a case of Addisonian anemia of a chronic course, Thayer observed characteristic ameboid movements in a megaloblast. This observation is apparently the first of this nature. This megaloblast showed typical ameboid movements. Small round pseudopodia were projected into which the colored protoplasm flowed in the same manner seen with the ordinary intestinal amebas. Slight changes in shape occurred at times in the nucleus. The movements of the cell were marked, strikingly like those in leukocytes, and entirely unlike the gradual changes of shape sometimes seen in red blood-corpuscles in the fresh specimen. The pseudopodia that projected were exactly like those seen in the movements of a polymorphonuclear leukocyte; that is, on the edge of the

2. Digitalis in Heart Disease.—Dropsy in cases of heart disease, in which the auricles are in a state of "fibrillation" and functionally inactive, Windle says, is present in a large proportion of cases of severe heart failure, whatever the nature of the underlying lesion may be. He has found the benefit derived from the administration of digitalis in cases of severe heart failure variable, even when classical indications for its use are present. In some patients improvement is rapid and maintained—the heart decreases in size, the edema quickly disappears; its power for good is limited—improvement occurs to a certain extent, and then comes to a standstill; again, particularly in cases of mitral stenosis with regular pulse, and those resulting from arterial disease, digitalis is often impotent or even harmful—the heart continues to dilate, and dropsy increases under its use. The mode of action of digitalis in fibrillation is as yet imperfectly understood. There are good reasons for the supposition that the drug acts by depressing the conductivity of the *a-v* bundle; its full effect is to block the passage of stimuli from auricle to ventricle; cut off from the influence of the auricle, the ventricle beats an independent rhythm. However this may be, the fact remains that the character of the heart's action under the full influence of digitalis in this condition is comparable in every way to that occurring in complete heart-block. The rhythm of the heart at times becomes regular, with a rate of 40 or thereabouts; further, a frequent effect of continued full doses is the occurrence of "coupled heart beats." The weaker beat of this coupled rhythm, which occurs with notable regularity, arises in response to a ventricular stimulus, and it is supposed that a condition of complete heart-block is present.

While the majority of cases of fibrillation respond in a marked manner to digitalis, it is found, as a matter of experience, that reaction varies under different circumstance of etiology and rate of pulse. Cases which respond most certainly and rapidly are those resulting from old rheumatic lesions, in which the rate of pulse is not greatly above normal, and symptoms of failure arise gradually. There is another type of case, also of rheumatic origin, in which fibrillation occurs suddenly, and heart failure soon becomes extreme; in these cases the pulse is usually rapid and reaction is uncertain. Fibrillation not uncommonly ensues in the course of arteriocardiosclerosis; generally the reaction is slight or absent, occasionally the heart slows to some extent, but improvement in the general symptoms is not proportionate. Exceptionally typical reaction occurs. Generally speaking, Windle says, improvement in cases of this kind is proportionate to the degree of slowing of the heart; and digitalis must be given in sufficient doses to reduce the rate at least to the normal, and in most cases considerably lower, to get the best results. On commencing treatment, 15 minims of the tincture should be given four times a day until the pulse slows to from fifty to sixty a minute, which it will do, as a rule, within a week. In most patients the improvement with this rate of pulse is maintained, when the same dose should be given three times a day and its effect watched. In others the case hangs fire; the drug should then be pushed until its full physiologic effect on the pulse is produced. The evidence of this is either a regular slowing of the heart to about forty beats a minute, or the occurrence of coupled heart beats. A pulse of fifty or over is always characteristically irregular; when the rate falls below fifty, it exceptionally becomes regular, the number of heart beats being the same as the pulse. More frequently, the full effect is shown by the occurrence of coupled beats; these are readily recognized on auscultation—two heart beats follow quickly on each other, succeeded by a long pause, the first beat is strong, the second short and feeble.

From a large number of observations, Windle has found that the total amount of tincture of digitalis required to produce runs of coupled beats or regular slowing is, on the average, 450 minims—that is, in about ten days with doses of 15 minims. Digitalis should be stopped when long runs of coupled heart beats or regular slowing occur; no further good can follow its continued use; the full effect is transient; within two or three days the pulse quickens and is again cell there appeared sometimes very small round buds, several at a time, which coalesce and form larger processes. The absolute homogeneity of the protoplasm did not allow Thayer to observe the rolling motion so clearly as in the case of *Amœba coli* or a leukocyte containing granules. At times, however, the movement was really rather active. Thayer concludes that in the early stage of development represented by the megaloblast, the red blood-corpuscle is, probably, a cell with powers of active progression.

99. **Function of the Sino-Auricular Node.**—The experiments reported by Cohn and Kessel were done on the excised hearts of small dogs, which had been perfused with Locke's solution. The plan differed from the other series of experiments, in that, first, an attempt was made to excise only the known node-bearing area, and, second, to show that even multiple incisions did not influence the rate (except to accelerate it), while a final incision which cut away the window that had been made on three sides, in ten of sixteen experiments did successfully cause the stoppage of the entire heart. In two the stoppage is not noted in the protocol, though the rates fell from 114 to 81.9 in one, and from 121.5 to 63 in another. In three others the node is probably not excised, and in a fourth final incision was not made. The experiments gave a fairly uniform result. The authors conclude that normal impulse formation takes place and normal rate is produced in the sino-auricular node.

100. **Bacillus of Leprosy.**—Pure cultures of *B. lepræ* have been obtained by Duval and Gurd directly from the infested leprous tissue on a variety of special media including tryptophan and glycerinated blood-agar without first growing them in the presence of amebas and their symbiotics. From two cases of leprosy they have cultivated in pure growth the specific organism directly from the tissues on Novy-McNeal rabbit blood-agar to which 1 per cent. glycerin had been added. As a rule, multiplication of *B. lepræ* on artificial medium takes place slowly, but once the growth has started it can be readily accelerated by frequent transplantation. They have succeeded in cultivating *B. lepræ* from the cutaneous nodules in eight cases of leprosy, two cases of nasal discharge, and from the experimental lesion in a number of monkeys and white and Japanese dancing mice. That the cultures are leprosy bacilli, and not some other acid-fast species, has been definitely proved by cultural and animal tests. Their experimental study on the virulence and viability of leprosy bacilli shows the necessity of early diagnosis and the need of strict segregation of certain types of the disease. The length of time *B. lepræ* will live and retain its infectiousness outside the body indicates plainly the risk to a community in allowing leper patients at large, in particular those who have open lesions. Especially dangerous from the standpoint of source of infection are the patients discharging the bacilli in the secretions from the nasal mucous membrane. These patients are a constant menace to those with whom they associate because of the possibility of indirect transmission of the bacilli that are unconsciously deposited on articles about the household where the leper resides. The mere fact that the organism lives for so long a time outside of the animal body may, the authors believe, explain why the disease continually reappears in households that have harbored a leper. The bacilli escaping from the infected individual, who for months may not be aware of his malady, are a constant menace to others of the household or to subsequent tenants, even though it be years after the direct source of infection has been removed.

The animal experiments do not tend to support the view that leprosy may reside for years in the human body before manifesting any outward signs of the disease. Direct inoculation from man to man may occur, but it is the exception. On the other hand, in the light of present knowledge the indirect evidence of transmission is by far the more significant. Their investigations also confirm the belief that the mucous membrane of the nasal pharynx is the port through which the bacilli gain entrance to the body, as well as the chief source from which infection spreads. The results of animal experimentations demonstrate the fact that direct communication of the disease may take place from individual to individual without the presence of the bed-bug or other parasites as intermediate hosts. In the examination of blood from patients suffering from leprosy the serum has been shown to contain specific antibodies of different kinds against certain constituents of the *B. lepræ*. In addition to the presence of specific bodies, they have demonstrated that complement is present in normal quantities. Agglutinins are present, though not in very large amounts. The opsonic content is probably affected at different stages of the disease, but with reference to the activity of this body their researches have so far not proved conclusive.

On commencing treatment, 15 minims of the tincture should be given four times a day until the pulse slows to from fifty to sixty a minute, which it will do, as a rule, within a week. In most patients the improvement with this rate of pulse is maintained, when the same dose should be given three times a day and its effect watched. In others the case hangs fire; the drug should then be pushed until its full physiologic effect on the pulse is produced. The evidence of this is either a regular slowing of the heart to about forty beats a minute, or the occurrence of coupled heart beats. A pulse of fifty or over is always characteristically irregular; when the rate falls below fifty, it exceptionally becomes regular, the number of heart beats being the same as the pulse. More frequently, the full effect is shown by the occurrence of coupled beats; these are readily recognized on auscultation—two heart beats follow quickly on each other, succeeded by a long pause, the first beat is strong, the second short and feeble.

From a large number of observations, Windle has found that the total amount of tincture of digitalis required to produce runs of coupled beats or regular slowing is, on the average, 450 minims—that is, in about ten days with doses of 15 minims. Digitalis should be stopped when long runs of coupled heart beats or regular slowing occur; *no further good* can follow its continued use; the full effect *is transient;* within two or three days the pulse quickens and is again characteristically irregular. The drug should now be given again in increasing doses of from 10 to 15 minims, three times a day, until the pulse slows to a rate approximating that at which the double beats previously occurred; it is with this rate of pulse that the patient will generally be at his best. The guide for dosage during treatment is the effect on the heart, and this can be determined by auscultation, the rate and rhythm of the beats furnishing the necessary indications.

3. **Death from Postanesthetic Acid Intoxication.**—Since the occurrence of these cases reported by Brown, the urine of every child in the *Liverpool Royal Infirmary* is tested for acetone, on admission; if this be present the operation is delayed, if possible, till the acetone has been eliminated, and treatment is continued after the operation. Inasmuch as an individual deprived of carbohydrates excretes acetone and diacetic acid, but the exhibition of carbohydrates rapidly causes the disappearance of these substances, glucose is employed as a prophylactic. All patients admitted to surgical wards for operation (usually admitted 2:30 p. m.) receive (1) glucose 1 dram, at 4, 6 and 8 o'clock on the day of admission and at 4, 6 and 8 o'clock on the following morning. If the child is 8 years or older, 2 drams are given. (2) Sodium bicarbonate, in the strength of 1 dram to 4 ounces of water, is given instead of plain "wash-out" before operation. If acetone is present in the urine on admission: (1) glucose is continued at two-hourly intervals during the day-time; (2) the sodium bicarbonate is given every two hours during the day and every four hours at night. Liquid glucose is more satisfactory than solid, and children take it as well as a sweet. Sodium bicarbonate solution is frequently taken by children only after a struggle. Since the initiation of this measure no serious symptoms have developed in any patient; but the treatment has not been in force long enough to give a reliable comparison, though the post-anesthetic vomiting has been less.

5. **Roentgen Rays in Malaria.**—The effect of heat applied over the splenic area in relieving the pain attendant on an attack of malarial fever gave Skinner and Carson the idea that the Roentgen rays also might have a therapeutic action as the immediate effect of their similar application. That these conjectures were not without base is evidenced by the eleven cases reported. The application of Roentgen rays in cases of malarial fever relieves splenic pain and reduces recent engorgement; the temperature falls and does not usually rise again, and recovery is not attended by the anemia usually present in patients treated with quinin. The authors have not had to fall back on quinin in patients treated by the Roentgen rays, while they have had patients who resisted quinin and yielded promptly to the rays (quinin being discontinued).

9. **Immunity Reaction in Diagnosis.**—Quantitative estimations of the strength of a serum in antibodies, as estimated by the Bordet-Gengou reaction, are not, in Emery's opinion, applicable in all cases, at least so far as tuberculosis is concerned. What it may be expected to give is a measure of the amount of tuberculous substances in the serum, which in association with the clinical facts, may have great value in diagnosis, and perhaps also in prognosis and treatment. He examined thirty-four individuals with diseases other than tuberculosis and healthy persons. The average complement absorption time was 18.1 minutes, the maximum 35 minutes, and the minimum 2½; this shortened time was present in but three persons who were not thought to be tuberculous. In tuberculous individuals the most usual thing is to find the absorption time greatly reduced. In Emery's cases the average time was 7.4 minutes, and times of less than 2½ minutes were found in 25 out of 56 serums examined, or 44.6 per cent. Thus, he says, if we regard an absorption period of 2½ minutes as affording the criterion for the presence or absence of the test, we find it in 44.6 per cent. of the tuberculous and 8.8 per cent. of non-tuberculous individuals. If we take 5 minutes, we find it in 66 and 11.7 per cent., respectively. Further, tuberculous persons do not always give a shortened absorption period. Very short absorption times are usually encountered in chronic cases in which the patients are doing well, and in quite general terms are, in definite tuberculosis, longer in cases in which the patients are progressing rapidly. The process, therefore, has some value in giving a clue to the prognosis. But it is very far from being absolute. Thus it appears that a prolonged absorption time may be due (1) to the presence of antibodies in minute amounts only (this occurs in health or in tuberculosis, and as a rough general rule indicates a progressive disease); and (2) to the presence of this inhibiting substance (this does not necessarily indicate a bad prognosis). Judging from the few cases in which Emery has been able to put the matter to the test, he concludes that a prolonged absorption time in a case of undoubted tuberculosis indicates a high degree of susceptibility to tuberculin, whether applied to the skin or injected; but a patient with a shortened time will also react.

10. Also published in the *British Medical Journal*, Feb. 25, 1911.

11. **Treatment of Pneumonia.**—Lees presents a review of well-known facts and does not offer anything new.

16. **So-Called Insusceptibility to Vaccination.**—The "one-mark vaccination" is strongly condemned by *Staple. It is* perfectly obvious, he says, that if a child is vaccinated in only one place there is less likelihood of the operation being successful than if it were performed in the orthodox number of places. Staple regrets that when a certificate of insusceptibility is filled up the practitioner is not required to certify that the child has been unsuccessfully vaccinated in three or four marks on three separate occasions.

18. **Placental Anaphylaxis.**—The idea underlying Johnstone's theory of placental anaphylaxis was that some alien protein might pass from the fetus or placenta into the maternal circulation, and supersensitize the mother; and that a *subsequent transference of the same substance after a suitable* interval might account for the onset of convulsions and other symptoms. His experiments were confined to the use of the placenta only. They fall into five groups. In the first group he used an extract of placenta from an eclamptic patient. In the second group he carried out similar experiments in twelve female rabbits with the juice of normal healthy placenta. In the third group, the conditions were made as realistic as possible, pregnant animals being injected with the juice of placenta from another of the same species. In the next two groups Johnstone used powdered placenta suspended in normal saline solution. Anaphylactic symptoms were obtained by the use of normal placenta juice in eight out of twelve rabbits. This indicates that human placenta juice contains

some complex protein body which is capable of acting as a toxin for other animals. No results followed the use of eclamptic placenta juice. So far as it goes, this may be taken to lend support to the view that the toxic element had passed out of the placenta into the patient's body. No result followed the use of extracts of animals of the same species. Finally, no results followed the use of powder of placenta, either human or of animals of the same species.

The question remains: Were such anaphylactic symptoms as were obtained, due to a placental toxin, or to the small quantity of blood-serum inevitably present? It is impossible to wash all the blood out of a placenta by any method yet devised—either the simple one employed in Johnstone's experiments, viz., washing the minced placenta in a muslin bag under running water, or the more elaborate, but not more effectual one, of injecting water into the umbilical vein immediately after birth. The results of these experiments, particularly the failure to confirm Anderson and Rosenau's results with homologous placental extract, in Johnstone's opinion appears to support the view that there is no evidence of anything of the nature of anaphylaxis, so far as we at present understand that subject, in the commoner manifestations of the toxemia of pregnancy.

27 *Absence of Abdominal Respiratory Movement as an Indication of Pericarditis. W. E. Wynter.

27. **Absence of Abdominal Respiratory Movement an Indication of Pericarditis.**—The sign suggested by Wynter is inhibition of the action of the diaphragm, indicated by suppression of normal abdominal respiratory movement. In acute pericarditis, on the other hand, the cessation of phrenic action is bilateral and, consequently, absence of abdominal respiratory movement is as obvious as in abdominal disorders, though other abdominal manifestations, such as muscular rigidity and general tenderness, are lacking. The author says that when the front of the body is fully exposed, the stillness of the abdomen is very striking, suggesting peritonitis, unless, as sometimes happens, there is inspiratory recession, which might mislead unless the want of correspondence with the movement of the upper chest is noticed. The inertness of the diaphragm is not merely inferred, but by Roentgen-ray screen examination can be actually observed, the midriff mounting high into the thorax and exhibiting no contraction; in some instances there is an actual rising of a quarter of an inch with each inspiration. In one case the contents of the upper abdomen, such as the kidneys and opaque masses in the intestines, could be seen to participate in this upward respiratory movement. Concomitant and consequent phenomena are: a tendency to dilatation of the hollow abdominal organs, especially the stomach; collapse and loss of function in the lower lobes of the lung; slight upward displacement of the heart, and of the organs beneath and in contact with the diaphragm. Loss of abdominal movement, as a sign of pericarditis, is the more valuable in that it may precede and outlast the other indications and so afford grounds for anticipatory or retrospective diagnosis. The condition affords a reasonable explanation of the cyanosis and dyspnea so usual in the complaint, and of the upright position so commonly assumed by the patient, the former expressing the effect of respiration restricted to the function of the upper lobes of the lungs, and the latter pointing to an unconscious effort on the part of the patient to utilize the weight of the abdominal viscera to depress the passive diaphragm and enlarge the thoracic area. Restriction of abdominal movement is apparently more marked in fibrinous than in effusive pericarditis, movements being more productive of local irritation in the former than in the latter condition, as is the case in other serous sacs, such as the pleura and peritoneum.

31 *Treatment of Heroinomania and Morphinomania. P. Duhem.
32 Two Cases of Abscess of the Liver Complicating Appendicitis. J. J. Clarke.

30. **Surgical Aspect of Glycosuria.**—Amputation for diabetic gangrene is favored by Morton, but he says that we ought to consider carefully in what cases of diabetic gangrene amputation is called for. If the area is small, and the gangrene is not spreading, he sees no reason why amputation should be done, unless the process of separation of the dead tissue is so tedious that the patient desires to have an operation which may hasten matters. If so, a thorough removal of sloughs may suffice; but if the gangrene is spreading, or is associated with great pain in the living margin of tissue, or there is pyrexia due to septic absorption from the gangrenous area, then the question of amputation must be considered seriously. If the most scrupulous care is taken as to antiseptic details, and spinal anesthesia is used, the risk of amputation should not be great. Morton reports three cases:

CASE 1.—Dry gangrene of the great toe, due to atheroma of the arteries associated with diabetes. S. C., aged 66, was admitted to the General Hospital in October, 1907, with dry gangrene of the great toe. The necrotic area in part separated, and was in part removed, but the gangrene spread to the next toes, and the neighboring part of the foot. No pulsation could be felt in either the posterior tibial or the dorsalis pedis artery in either foot, and the radials were thickened. The popliteal arteries could be felt pulsating on both sides. Glycosuria persisted during the six months the man was in the hospital, but considerably decreased on antidiabetic diet. Amputation was performed through the knee joint under spinal anesthesia which acted well. The popliteal artery was very rigid and thick, and the arteries of the amputated leg were found to be extensively affected by atheroma. The lumen of the posterior tibial was almost completely blocked, and that of the anterior was very small. Primary union occurred except at one minute point and the patient was in no way the worse for the operation.

CASE 2.—Moist gangrene of all the toes, of an inch of the foot close to them, and a large patch of gangrene extended down the sole almost to the heel. Amputation was performed successfully through the knee-joint under spinal anesthesia.

CASE 3.—Spreading moist gangrene of foot associated with perforating ulcers. Amputation through knee-joint was successful.

31. **Heroinomania and Morphinomania.**—Instead of attempting to wean the patient in five or six days, Duhem devotes two or three weeks or more to the suppression of injections. He encourages the elimination of toxic products, the disengorgement of the glandular canals, and the renovation of the epithelial tissues by all possible means. He makes use of any symptomatic treatment for which there may be an indication.

34. **Fibromas Complicating Pregnancy.**—Recent discussions of this subject in French medical societies have shown that the pregnancy generally runs a normal course to term, notwithstanding the presence of the fibroma. Only when serious disturbances are threatening is it necessary to interfere. At the same time it is conceded that the disturbances must not be allowed to reach such a stage that operative measures are liable to come too late. Mouchotte's patient was pregnant for the first time at the age of 38. The uterus was found studded with fibromas. A large one was attached to the uterus only by a pedicle, seeming to belong to some other

organ, especially as a loop of intestine had become interposed between the uterus and the body of the big fibroma. The serious symptoms seemed to be characteristic of intermittent hydronephrosis, owing to the compression of the left ureter, sigmoid flexure and the iliac blood-vessels which complicated the picture. When the abdomen was opened, the general fibromyomatous degeneration of the uterus and the slight possibility of effectual hemostasis, induced Mouchotte to remove the entire uterus as the only safe procedure. He emphasizes in conclusion that the outcome with fibroma of the pregnant uterus depends less on the size of the tumor than on its location, the accidents being more or less serious according to the organs compressed by it.

40 *Supernumerary Kidney. (Rein surnuméraire constaté pendant la vie.) A. Isaya.

37. **Calculus in Ureter.**—Fabricannte advocates, as giving the best access, a transverse incision around the iliac crest, parallel to Poupart's ligament. In very favorable cases in women, the stone might be removed through the vagina.

40. **Supernumerary Kidney.**—Isaya's patient was a woman of 27 with recurring attacks of pain since childhood. A tumor was discovered which proved to be a third kidney. But all three kidneys were apparently normal, and the pains were remedied by fixation of the transverse colon which was found sagging. All symptoms ceased after the operation. Isaya reviews the few similar cases of supernumerary kidneys on record.

45 *Inversion of the Vagina Following Hysterectomy. P. Guibal.
46 Bone and Joint Complications of Malta Fever. D. Zezas.
47 *Drainage of Ascites into Subcutaneous Cellular Tissues. P. Mauclaire.

41. **Ambulatory Treatment of Fractured Leg.**—Worms and Hamand have applied Delbet's walking splints in a number of cases of oblique fracture of the leg or Dupuytren's fracture, and describe here the good results in eight typical cases. They illustrate the technic; the principle is to support the leg by plaster splints from a point above the fracture close to the condyle above, and below just above the bulge of the malleoli. These points sustain the two rigid splints which support the leg in the place of the fractured bones, the weight of the body thus being transmitted from the upper end to the lower end of the leg, leaving the focus of the fracture in repose. All that is necessary is a splint of plaster on each side of the leg, with a horizontal plaster bandage wound around just below the knee and another at the ankle including the heel. The simplicity of the technic and the excellent outcome are extolled. They apply the apparatus immediately after the accident, especially with simple fracture permitting easy and rapid reduction. If the limb is already much swollen, it is better to wait and use other means for immobilization until the effusion has been absorbed. Even compound fractures can be treated by the ambulatory dressing, they assert, if asepsis can be assured and the patient is not allowed to walk on the limb except with great caution until after the soft parts have healed.

43. **Treatment of Chloroform Accidents.**—Vidal concludes from study of the literature and his own experience that the main point in treating chloroform accidents is to supply the heart with a non-toxic fluid. He thinks that artificial respiration will generally answer the purpose when the trouble is merely arrest of breathing. Oxygen is required only exceptionally, but if the heart has stopped beating he advises (1) exposing at once a vein close to the heart and removing 300 gm. of blood by pressure on the chest; the vessel is then ligated; (2) keeping up artificial respiration constantly; (3) then injecting slowly, toward the heart, through a needle inserted in an artery on the right side, from 80 to 100 gm. of tepid Locke's solution; (4) then waiting two minutes before doing anything else; (5) then squeezing the heart through the diaphragm, superficially and slowly, not over thirty times a minute, keeping this up for one minute then (6) waiting for two minutes; (7) giving another injection of Locke's solution (only 60 gm.) and resuming massage after the fluid has been in the heart for two minutes. This outline of treatment is the only logical method, he thinks, and the success that has been obtained with other methods, he is convinced, was due to the fact that unconsciously some of these principles were followed. His formula for Locke's solution is sodium chlorid, 9 gm.; calcium chlorid, 0.2 gm.; potassium chlorid, 0.2 gm.; sodium carbonate, 0.2 gm.; glucose, 1 gm., and distilled water, 1,000 c.c. The benefit from this intracardiac lavage has been instructively shown in some recent communications, he states, that of Depage reporting the instantaneous revival of the heart, which forty-five minutes of massage had been unable to accomplish. He warns against too hasty massage, as that would force the non-toxic fluid out of the heart. The aim is to save for the heart the whole *benefit of its first effort.*

45. **Prolapse of the Vagina.**—Guibal discusses means to prevent and remedy inversion of the vagina, especially after hysterectomy, giving the details of six cases on record with one from his own experience. In his case he was obliged to excise part of the vagina and restore the perineum which had been lacerated at the last childbirth, twenty-five years before. Three months after vaginal hysterectomy, the vagina became completely inverted. He gives the details of the complicated operation which restored approximately normal conditions.

47. **Dangers of Drainage of Ascites into the Subcutaneous Cellular Tissue.**—Mauclaire has treated six patients by inserting a T drain, the vertical branch projecting into the pelvis while the horizontal branches extended in the subcutaneous tissue. This provided a means for the ascitic fluid to escape into the cellular tissue, but the outcome was not good. Four of the patients rapidly grew weaker and soon succumbed. Another seemed to bear the drainage without disturbances but succumbed to progressive cachexia. The sixth patient recovered; the ascites in this case was tuberculous and the laparotomy alone might have sufficed for the cure. He wore the drain for three months without inconvenience and the ascites did not recur. It is possible that in the four fatal cases the ascitic fluid accompanying the cirrhosis or cancer was so toxic that it injured the patient when reabsorbed. Possibly the outcome might have been better if a smaller drain had been used instead of the No. 15 or 16 Charrière that had been selected. Mauclaire thinks that the possible toxicity of the ascitic fluid and the danger of grafting tuberculosis or cancer should compel caution in these efforts for autodrainage of ascites.

48. **Dulness Over the Heart in Cardiac Disease in Children.**—Nobécourt and Voisin compare the percussion findings in thirty-six children with various cardiac defects; in two the trouble was congenital, in two others of tuberculous origin. In the latter cases the heart area was little if any increased, and soon subsided to less than the normal area. Necropsy disclosed the heart much atrophied. In twelve cases the trouble was an acute cardiopathy, and in the others a chronic condition. If the apex is found at the same point on repeated examinations, while the general area has diminished, adherence to the chest wall may be assumed. In the course of an acute heart affection, an increase in the size of the precordial dulness may indicate restriction of fluids, venesection,

digitalis or epinephrin. Strict repose should be enforced during convalescence as long as the heart area is unduly large. Reduction in the area of the dulness is one of the last signs of improvement under heart tonics. It is not necessary, they add, to percuss the entire heart; determination of the apex and of the point of intersection of the upper margin of the liver with the right margin of the cardiac dulness is all that is generally necessary. These points can be readily percussed and the variations in the horizontal diameter instructively determined.

54 *Value of Tincture of Iodin for Antisepsis. P. Reclus.

54. **Tincture of Iodin and Antisepsis.**—Reclus congratulates the profession on the present vogue of tincture of iodin which he regards as the most easily managed of all antiseptics, the least dangerous and the most powerful. He cites a number of instances from his own experience to sustain this, calling attention in particular to the ideal functional outcome in injuries of the hands treated with the tincture of iodin. The skin heals supple, the joints are not at all stiff and the skin grows out to cover the bare bone when conditions permit it in the slightest. The outcome is almost equally good when the iodin is not applied until after signs of local inflammation and even of septicemia have developed. In one case the hand had been crushed by a keg holding 500 liters and two days had elapsed, the tissues putrefying, and signs of general infection were already installed before the tincture of iodin was applied, and yet functioning was restored, except for disarticulation of the forefinger, in a manner little short of miraculous. In another case, he says, he operated only by a sort of professional reflex action as the patient seemed moribund from fulminating gangrene from a scrotal tumor resulting from puncture of a hematocele by unskilled hands. Reclus made the incision with the actual cautery which lighted the gas in the focus; it burned with a blue light. He then cleared out the clots and gangrenous tissues and painted the walls of the enormous cavity with tincture of iodin. It was a surprise to find the man alive the next day; by the end of forty days the immense cavity had nearly healed and the man is now completely restored to health.

56 Treatment of Skull Wounds on the Battle Field. (Du traitement des blessures du crâne dans les formations de l'avant.) Weitzel.
57 *Ultimate Outcome of Dislocation of the Shoulder. (Pronostic éloigné des luxations de l'épaule.) L. Imbert and G. Dugas.
58 Treatment of Arterial and Arteriovenous Hematomas. C. Monod and J. Vanverts. Commenced in No. 1.

55. **Operative Treatment of Typhoid Gall-Bladder Disease.**—Quénu published two years ago a work on this subject, reviewing forty-five operations that had been done on the gall-bladder during typhoid fever or convalescence therefrom. He here completes the list to date and tabulates the details of the sixty-seven operations. Only one of the patients recovered of the twelve treated by an incomplete operation, while thirty-three recovered of the forty treated by cholecystostomy and all but two of the ten with cholecystectomy. [The only cases cited from The Journal are those of Lavinder and Prince.] The general conclusion from this material is that cholecystostomy alone answers in nearly every case. Only when the gall-bladder tissue is too friable, or when there is perforation or ulceration, is its removal indicated.

57. **End-Results of Dislocation of the Shoulder.**—Imbert and Dugas have been investigating the present condition of fifteen patients, the only ones they have been able to trace to date out of eighty patients treated for dislocation of the shoulder in the last few years. Only four of the fifteen were found in a satisfactory condition—all the others complained of more or less disturbance in the use of the arm. The patients were between 30 and 70, but the four with a satisfactory outcome were between 34 and 58. Delay in reduction of the dislocation does not seem to be the decisive factor for the outcome; in six of the cases with the poorest ultimate outcome reduction had been done in one hour, the same day or the second day. The reduced dislocation had been given careful treatment in all cases, in one for five months, in others for four months, etc., by experts in electric and mechanical therapeutic measures. In all the severer cases there had been periarthritis and the persisting pain and atrophy of the muscles indicate participation of the nerve terminals in the trouble. From the standpoint of industrial insurance it is important to bear in mind that even under the best conditions functional disturbance and pain may persist for several months or may become permanent so that it is impossible to judge definitely of the case under several months. Persisting incapacity is generally due to the periarthritis, and only exceptionally to traumatic paralysis of the brachial plexus.

61. **Beriberi.**—Barbézieux writes from Indo-China to present arguments in favor of the assumption that beriberi is not a distinct morbid entity but a syndrome for which disturbances in the general nutrition are responsible. It develops only in the predisposed, that is, in those in whom the nervous system has been modified by some inherited diathesis. Acute rheumatism, malaria and dysentery may prove the occasional cause, equally with poverty, neurasthenia, overwork, grief, insufficient food or puerperal or alimentary intoxication. The sodium salts and especially sodium salicylate have not only a symptomatic efficacy but seem to arrest the degeneracy of the central or peripheral nerve tissue and to favor the regeneration of the nerve cells. The sodium salts, he says, seem to facilitate the exchanges and the interaction of the intracellular metallic ions. His experience has confirmed the preponderant rôle of sodium salicylate in the treatment and cure of beriberi. In a typical case reported, the beriberi followed acute rheumatism and sodium salicylate was given by subcutaneous injection for the rheumatism and the beriberi subsided with it. Since then he has been applying the method systematically in the clinic. The neuro-arthritic diathesis seems to be the most frequent and important factor, and this he has found extremely common in tropical countries.

63. **The Test Diet in Estimating Digestion.**—Cecikas has studied on a number of volunteers and patients the findings with Schmidt's test diet. His experience shows the value of the method in organic affections of the digestive tract, but his conclusions differ from Schmidt's in regard to the interpretation of the findings with functional disturbances.

Semaine Médicale, Paris

64 *Auscultation Sign of Glandular Disease in the Chest. (Le signe de D'Espine dans le diagnostic de l'adénopathie trachéobronchique de l'adulte.) M. Roch.

64. **Vertebral Auscultation in Diagnosis of Bronchial Adenopathy.**—The Journal, March 9, 1907, page 909, described D'Espine's sign of disease of the glands in the chest in children, namely, the peculiar resonance found in auscultation along the spine as the child speaks, or, preferably, whispers. He makes the test by having the child say the French words for 333, *trois cent trente- trois.* Roch has been studying this sign in adults, and states that it is proving equally instructive at all ages. He found it pronounced in thirty patients, mostly those with pulmonary tuberculosis. The peculiar resonance is the result of the transmission of the sound waves from the bronchial tree to the chest wall by intermediation of the diseased glands. Bending the head forward brings the trachea closer to the spine and this magnifies the characteristic findings. In two cases the findings gradually became negative as enlarged glands in the neck subsided to normal size; he accepts this as evidence that the bronchial glands share in a process affecting the submaxillary glands. With differential vertebral auscultation it must be borne in mind that the bifurcation is higher proportionately in the child than in the adult. Roch discusses the possible sources of error, but concludes from his experience that the sign is destined to prove of great clinical value. It is possible, he adds, that it may not only reveal incipient tuberculous lesions, but may disclose cancerous involvement of the glands in question in certain cases. [Gray's article on vertebral auscultation, to which Roch refers in the course of his article, was reviewed in these columns Aug. 22, 1908, page 709.]

72 Torsion of Hour-Glass Stomach. (Achsendrehung der Pylorushälfte eines angeborenen Sanduhrmagens.) A. Schüle and P. Walther.

66. **Movable Cecum.**—Straschesko reports from Kiev the case of a man of 34 subject to sudden transient attacks of abdominal pain without rise in temperature, but accompanied by distention of the abdomen, nausea and obstinate constipation, the attacks of colic sometimes terminating in transient diarrhea. Palpation gave different findings at different times, and the operation revealed an abnormally movable cecum with defective development of the ascending colon and a single mesentery for both ileum and cecum. The colic is the result of torsion or kinking and the following local peritonitis; the latter may entail adhesions which further complicate the picture and there may be incarceration. The syndrome is often mistaken for chronic appendicitis, but appendicectomy does not cure it. In Straschesko's case the patient was permanently freed from all trouble from this source by cecopexy, the cecum being fastened in the right iliac fossa with six catgut sutures to the parietal peritoneum. Palpation of the intestines is the best means to detect the trouble. Roentgen-ray examination confirming the findings. The kinked bowel became incarcerated in a fatal case recently reported by Heiler. Movable cecum does not cause symptoms in the majority of cases; it is comparatively common, Hausmann having collected 143 cases in six years.

71. **Volvulus of the Stomach.**—Mühlfelder gives the details of twenty-three cases on record and of a case in his own experience. All ages are represented in the list; most of the patients had had gastric disturbances for some time before, some even relating that they had had transient subjective sensations previously, like those of the definite volvulus. It is inevitably fatal in a few hours or days unless it retrogresses or is surgically corrected. In some cases the abd men was opened, but the true condition was not recognize even then, and the patients succumbed. There is no patl ognomonic symptom; the main point is to bear in mind tl possibility of volvulus and weigh carefully all the minor ph nomena observed. In one case a man of 41 suddenly deve oped vomiting, with signs of obstruction of the bowel, di tention of the abdomen, retching and regurgitation of foo and drinks and a slowly increasing tumor in the left hyp chondrium. The operation revealed that the large tumo studded with patches of fresh fat necrosis and bound dov by fresh adhesions, was the stomach; the transverse colc lay above it, and in replacing the colon in its normal positic the stomach twisted around, showing that what had bee supposed to be the front aspect was in reality the posterio The patient recovered. In the personal case reported, a gi of 20 had had recurring appendicitis. The pains in the sic and stomach, cough and vomiting after eating persistir after appendicectomy were ascribed to incipient tuberculosi and tuberculin treatment was commenced. The epigastriu was tender, and on suspicion of complicating gastric ulce feeding was restricted to nutrient injections for a time, du ing which the pains in the stomach were arrested. On resun ing fluid food, the vomiting returned with weak heart actic and small pulse. The heart was entirely on the left sic and the area of dulness differed on different examinations i a puzzling manner. There was no protrusion or patholog resistance in the stomach region, and the patient could c fluid food, and stool followed an enema. Suddenly an acu attack of tetany was observed. This referred the disturl ances to the stomach, but the knowledge came too late, tl patient dying in a second attack a few hours later; necrop revealed the volvulus of the stomach. Mühlfelder seeks t explain the mechanism of volvulus and of the vomiting ac especially vomiting with gastroptosis as a factor in the vo vulus.

73. **Treatment of Fractured Malleolus.**—Bergemann thinl that all the advantages are on the side of an adhesive plast splint for a fractured malleolus. This permits proper fun tional treatment, obviates healing in a defective position, a the ultimate outcome is as good, he declares, as with Barde heuer's extension treatment without its drawbacks, heali being complete much sooner and with less trouble for tl patient. The correction by the adhesive plaster dressing supplemented by traction from a broad piece of elastic we bing drawn around the sole and hooked to one of a row hooks set in the anterior crossed broad strip of adhesi plaster. This permits graduation of the elastic traction, a the final results are good, as he shows by the tabulat details of twenty cases. Three illustrations show the exa technic advocated.

74. **Diverticulum in the Esophagus.**—Jurasz reports a typic case of a pharyngo-esophageal diverticulum resulting fro pressure from within on a defect in the muscular coat. Anal sis of the similar cases on record and the experiences wi this case confirm the advantages of gastrostomy as a prelim nary to the radical operation on the diverticulum whic especially with Lexer's technic for care of the stump, ensur a primary and permanent cure.

75. **Operative Treatment of Pancreatic Disease.**—Bo analyzes sixteen operative cases; the operation was done account of cysts in the pancreas in two cases, for cancer

one, for acute suppuration in the pancreas in three, for chronic pancreatitis in five, and for hemorrhage in the pancreas in five cases. This material is reviewed in detail, especially from the standpoints of etiology, diagnosis and technic. His observation has convinced him that necrosis of the pancreas is not a special affection, but merely one symptom that may be encountered with various affections of the pancreas, the result of inflammation or hemorrhage. Fat necrosis is found most constantly in connection with hemorrhage, probably on account of the fact that the accumulating blood destroys the epithelium and membrane, allowing the pancreatic secretion to get into the tissues between the acini. He warns against puncture for an assumed pancreatic cyst, with the abdomen unopened, as too dangerous to be attempted. Trauma was responsible for the hemorrhage in the pancreas in only one of the cases, but straining at stool may have been the causal factor in another case. Alcoholism was probably a cooperating factor in the others, and a tendency to obesity in some. Most writers describe the syndrome of hemorrhage in the pancreas and of acute suppurative pancreatitis as practically identical. In the cases reported by Bode the symptoms of hemorrhage came on suddenly after from two to six weeks of symptoms suggesting peritonitis or appendicitis. When the appendix was exposed, however, it was found intact in some of the cases, but signs of fat tissue necrosis pointed to the pancreas as the source of trouble. Only one patient recovered in this group of pancreas hemorrhage cases.

77. **Slanting Gall-Bladder Incision.**—Kausch makes the incision between and parallel to the course of the nerves in the abdominal wall, as he shows in two illustrations. If the umbilicus is in the way he excises it. All the soft parts are incised along the same line. The ultimate outcome seems to be good, as he has found on later examination of forty-eight patients.

78. **Dovetail Incision to Obtain Access to the Knee Joint.**—Kirschner describes his method of cutting into the extensor apparatus of the knee so as to open up the joint wide, while afterward restoring approximately normal strength to the extensor apparatus. Instead of a horizontal or median incision, he cuts out a trapezoidal indenture like the ordinary dovetailing method of fitting joists and boards together. A number of illustrations show the exact technic with which he is able to saw the extensor apparatus, the patella or upper part of the tibia to cut out the miter-shaped piece. The flap turned back permits ample access to the joint, while when the flap is replaced the broader trapezoidal top fits into its bed, conferring unusual strength and resistance on the severed parts. This dovetailing method may prove useful for other operations elsewhere, as for temporary resections, transplantation of muscles and tendons, etc., but he advises careful following of the directions he has formulated after extensive research on the cadaver. He adds that a little practice on the cadaver will much facilitate the cutting of the miter in bone. The method is scarcely adapted for children on account of possible injury to the epiphysis.

79. **Hour-Glass Stomach.**—Finsterer reports the details of five cases from the Graz clinic and summarizes sixty-six cases from the literature. The mortality has dropped from 100 to 13 per cent. since operative measures were introduced in its management, and this mortality is still declining as surgical treatment is instituted earlier. The indications for the operations are reviewed. He warns against general anesthesia on account of its injuring the stomach still further and possibly entailing acute dilatation.

80. **Two Thousand Goiter Operations.**—Oberst's communication issues from the Freiburg clinic; the patients were mostly from southern Germany and Switzerland, and the interval embraced in the statistics is from 1883 to date. Postoperative tetany developed in seven of the patients, and he emphasizes that every effort should be made to spare the parathyroids the slightest injury. This is easier said than done, he adds; perhaps the best plan is to refrain systematically from any interference with the region in which lies the recurrent nerve, as the parathyroids are generally in this part.

83. **Morphin Addiction.**—Schroeder has not found the results of sudden and complete deprivation of morphin any more serious than when the drug is tapered off. He gives the details of five typical cases to sustain his advocacy of sudden suppression under constant supervision.

86. Abstracted in THE JOURNAL, March 4, page 702.

90. **Left-Handed Children.**—Schaefer found that 692 of the 17,074 school children examined at Berlin were left-handed. This is a proportion of 4.06 per cent., but the boys nearly twice outnumbered the girls. Inheritance of the tendency was evident in 60.2 per cent. He discusses the anatomic causes for left-handedness, and denounces the present system in vogue which takes no account of the natural instinct to use the left hand as the main instrument, and compels all the children to use the right hand. Instead of training the left hand to expert skill, the training is wasted, he says, on the hand which Nature did not intend to have serve as the main instrument, and which will never attain the skill which the other might have attained.

91. **Reaction in Infant's Urine.**—Boschan's communication was summarized in Abstract 67 in THE JOURNAL, March 11, page 782.

100 Iodism and Thyroidism. Berg.

93. **Herpes Zoster and Renal Colic.**—Bittorf describes a case in which intermittent hydronephrosis in a wandering kidney induced occasional attacks of colic and during a recent severe attack herpes zoster developed, its location then corresponding exactly to the eleventh dorsal segment. The condition of irritation in the spinal ganglion evidently afforded a predisposition for the herpes zoster. In other cases on record, herpes zoster developed in Head's zone corresponding to the internal organ suffering from a painful affection. With an affection of the aorta, pain and hyperalgesia in the ulnar side of the left forearm may be the most important subjective symptom of the cardiovascular trouble. He has encountered this a number of times with pronounced sclerosis of the aorta.

95. **"Tuberculin Titer" Test.**—Möller has been applying the graduated technic introduced by Ellermann and Erlandsen [mentioned in THE JOURNAL, March 18, 1911, page 856]. His findings in 250 patients confirm those reported by others, but he does not think that any of the tuberculin superficial tests are able to determine positively whether the tuberculosis is active or latent. At the same time, when the tuberculosis is in the first or second stage a reaction to the cutaneous and intradermal tuberculin tests occurs with minute doses, too

small to induce any reaction in the non-tuberculous. Of nineteen patients in this group ten reacted positively to 0.0000002 gm. tuberculin, but 11.2 per cent. of 125 clinically free from tuberculosis gave likewise a positive reaction to this dose. There was a family history of tuberculosis in nearly all these positive cases. He thinks that the reaction in these cases indicates a tendency for the latent tuberculous focus to become active. Every patient giving a positive reaction should be given the benefit of special measures as if already clinically tuberculous, and should be frequently reexamined.

97. **Treatment of Syphilis.**—Traube states that the changes in the physical properties of drugs and in the blood under the influence of the drugs deserve greater attention. He has been studying them with his stalagmometer; this records the number of drops in a given volume of the fluid, comparing them with the standard number of drops of water. His research seems to show that the action of salvarsan is due essentially to its basic and precipitating properties, and he thinks that it may be possible to find other elements possessing the same physical properties and which thus may prove equally effectual in therapeutics while free from the drawbacks of the arsenic compounds. He is convinced that the physical properties of drugs rank in importance over their chemical properties, while chemotherapeutic research seems to have overlooked this fact mostly to date.

112 *Venesection in Treatment of Polycythemia. (Ueber Polyzythämie mit besonderer Berücksichtigung grösserer Aderlässe.) A. Hörder.
113 The Sympathetic Nervous System. (Das vegetative Nervensystem.) A. Frölich.

101. **Chronic Catarrh of the Large Intestine.**—Kolisch concludes his summary of the progress in late years in treatment of catarrh of the large intestine with the assertion that the only progress has been in the dietetic treatment, and this only by the better differentiation of the individual conditions by the functional tests, permitting regulation of the diet to conform to existing conditions. The possibility that the stomach may be primarily responsible for the intestinal trouble should never be forgotten.

104. **Fresh-Air Reclining in Severe Climates.**—Nöhring has the windows of the halls used for fresh-air reclining closed at night and the heat turned on in the morning, so that the floor and walls never get thoroughly chilled through although the big windows are all open to the floor during the day while the patients are reclining there. If the day is dry, he has a temperature as low as 32 F. in the halls but if the weather is damp he does not let the halls get colder than 50 or 52 F. Five years' experience has convinced him that this modification of the rigorous northern climate gives far better ultimate results than attempts to enforce the actual climatic conditions.

107. **Senile Chorea.**—Eichhorst describes two cases of typical chorea in a man of 80, and a woman of 73. In both the chorea developed after emotional stress; in both the chorea was on one side only and the necropsy findings were negative. The man died the fourth week after the onset of the right-sided chorea, and the woman during the fifth year of chronic left-sided chorea. In fifty-three cases of senile chorea on record, emotional stress was cited as a causal factor in 17 per cent.; 25 per cent. of the total fifty-five patients died soon after the onset of the chorea, and it became chronic in 49 per cent. In Bourneville's case, the chorea developing in a woman of 64 continued for twenty-four years. There was more or less mental disturbance in 43.5 per cent. of the cases; in 23.6 per cent. the chorea was unilateral.

112. **Polycythemia.**—Hörder adds another to the seventy or eighty cases on record of primary polycythemia. His patient was a man of 51, healthy until five years ago when enlargement of the spleen began to cause discomfort and a year later the signs of polycythemia became pronounced. Hörder regards the disease as a morbid entity involving the composition and distribution of the blood. Venesection, large amounts of blood being withdrawn, gave constant although transient relief in this case, the number of red corpuscles dropping by three or four millions and the other disturbances becoming attenuated after each blood-letting. It was repeated six times in the course of two months, from 150 to 700 c.c. of blood being withdrawn. The first count showed 10,700,000, with hemoglobin 130 per cent.; the last count, nine days after the fifth venesection, showed 9,500,000 reds.

114. **Reciprocal Relations Between Uterus and Ovaries.**—Henkel has had opportunity to examine these relations in 150 operative cases during the last few years. The findings can generally be classified in two groups: those in which there is an unusual number of follicles and those in which they are unusually scanty. In the first group the irritation from ripening of an unusually large number of follicles induces changes in the uterine mucosa which are liable to entail uterine hem[illegible]rhage. The hemorrhage in such cases must be regarde[illegible] a menstrual phenomenon, as it is the expression of the [illegible]ticipation of the uterine mucosa in the abnormally freq[illegible] ovarian processes. In such cases partial resection of the ovaries has proved an effectual means of removing the cause for this atypical menstruation. He found that it generally cured also any existing tendency to dysmenorrhea. In the other group, in which the organ is abnormally small and defectively developed, ovarian treatment seems to promote the further development of the ovaries and to cure the tendency to uterine hemorrhage. Palpation usually enables the two forms of ovaries to be distinguished. He makes it a principle to remove the ovaries with the uterus in case of myoma requiring laparotomy; the after-effects were no worse than when the ovaries were left, while the operative results were much better. His idea is that the uterus forms an integral part with the ovaries of the genital apparatus, and that the loss of one or the other destroys the functioning of the one left.

115. **Albumin Milk.**—Finkelstein and Meyer relate their further experiences with the albumin milk and emphasize the fact that it is not a food for healthy infants, and should not be given in conjunction with other food or milk. [The method of its preparation was described in The Journal, July 2, 1910, page 93.] They summarize here the special indications for this casein food.

116. **Influence of Appetite on Test Gastric Functioning.**—Fischer declares that the ordinary test meal pays too little attention to the appetite; a meal that is more palatable gives a much better oversight of gastric functioning. He has found extremely useful a breakfast in which the patient is allowed to select his beverage from the list: milk, coffee, tea, bouillon and weak lemonade, each 300 c.c. With this is allowed a roll or slice of bread (75 gm. bread), butter 20 gm. and 70 gm. of scraped raw meat, ham or sausage or two eggs or a herring. Comparative tests with this and the ordinary test breakfast showed that the "appetite breakfast" supplied much better information in regard to the secretory and motor functioning than the ordinary test breakfast.

117. **Conditions in Which Germs Pass Into the Blood.**—Sachs points out that the prognosis is very different when the germs are forced into the blood by some mechanical influence or primary absorption. The organism is generally able to conquer the germs invading the circulation in these cases. Conditions are different when there is chronic absorption of the germs and they are found to be proliferating in the blood; this indicates extra virulence.

118. **By-Effects of Salvarsan.**—Gilbert injected 0.2 gm. of salvarsan into the left gluteal muscle of a 9-year-old girl with parenchymatous keratitis; there was slight spastic paresis in the right leg and the Wassermann reaction was positive, although the parents denied syphilis. At the age of 6 there had been an obscure nervous attack and the paresis was possibly the sequel of a syphilitic meningitis at that time. Eighty-one hours after the injection the child was found unconscious in collapse, and epileptiform seizures developed, increasing in number and severity, with pulse 160, extreme cyanosis and foam at the mouth, so that a fatal outcome seemed inevitable, but the child gradually recovered in four or five days. If the collapse had occurred in the night, it is scarcely probable that the child would have been saved. Gilbert adds that slight paresis suggesting a possibility of meningitis in the past should contra-indicate salvarsan unless the patient can be kept under constant clinical supervision.—Sellei reports three cases of recent syphilis in which injection of salvarsan was soon followed by disturbances in hearing; in another case a syphilitic injury of the auditory nerve subsided under an injection of salvarsan.

119. See The Journal, April 23, 1910, page 1365.

122. **Typhoid Meningitis.**—Stühmer reports a case in which typhoid infection seemed to have localized exclusively in the meninges, typhoid bacilli being found in the cerebrospinal fluid obtained by lumbar puncture. The latter, he asserts, had an unmistakably curative effect on the meningitic symptoms. He has found eight cases of typhoid meningitis in the literature, in all but three of which the patients recovered.

123. **Inhalation of Nascent Mercury in Syphilis.**—Hubbes heats cinnabar (red mercuric sulphid) and has the patient inhale the fumes of the nascent mercury. In order to get rid of the sulphur he adds pure iron to the cinnabar; this binds the sulphur in the form of ferrous sulphid. Without the iron the sulphur forms the dangerous sulphur dioxid, but this is obviated by adding a corresponding amount of chemically pure iron. This nascent mercury seems to have an intensely toxic action on the spirochetes and combining with the hemoglobin follows them to the remotest parts in the body. He has seen the severest syphilis subside without recurrence to date under eight or ten sittings in the course of four or five days. He has had two and one-half years' experience with this method and has never had a failure, and affirms that with this method of using mercury there is no need to go farther afield for any other remedy.

135 *Dangers of Diverting Urine into Intestine. (Zur Operation der Blasenektopie bzw. zur Versorgung des Harnleiters nach Blasenexstirpation.) K. Spannaus.
136 *Treatment of Ankylosis of the Patella. A. Schanz.

135. **Dangers of Implantation of Ureter in Intestine.**—Spannaus reports two cases in which he successfully implanted the ureters in a stretch of bowel according to the technics recently advocated by Fink and by Goldenberg. Theoretically, the operation seems promising but in both of his cases the diversion of the urine into the intestine proved disastrous, the intestine evidently having absorbed noxious elements of the urine with resulting uremia, while the urine had a distinctly injurious action on the bowel mucosa. His first patient, a man of 43, had the bladder removed on account of hemorrhagic papilloma; a receptacle for the urine was formed out of an excluded stretch of ileum fastened outside the peritoneum. The wound healed smoothly but diarrhea developed two weeks later to which the man succumbed. The second patient was a woman of 40 with cancer developing on exstrophy of the bladder. The ureter was implanted in the excluded stretch of ileum and the wound was healing when symptoms of uremia became manifest and the woman died the seventh day.

136. **Ankylosis of the Patella.**—Schanz comments on the unsatisfactory results of the present methods of treating adhesion of the patella to the femur. When the adhesion is broken up, it has been only a question of time before the parts grew together again. This is avoided by the simple device of transferring the bursa between the patella and the skin to the space between the patella and the femur—thus merely changing the position of the bursa from the front to the back of the patella. He has done this in two cases and the procedure was so simple and easy and the result so ideal that he commends it for general adoption in treatment of ankylosis of the knee. The nutrition of the skin over the patella did not seem to suffer in the least in his two cases after removal of the bursa between.

139 *Progress or Going Backward? (Vermeintlicher Fortschritt und Rückzug.) E. Roth.

139. **Progress Forward or Backward?**—Roth thinks that the time has come to take stock of the boasted progress of the last fifteen years in medicine and see whether all of it can be regarded as an actual onward advance. Science has not escaped the blight of restlessness and haste characteristic of the age. New conceptions and methods are constantly being promulgated in the medical press and they are hailed as progress on account of the modern longing for change, but whether they really represent progress is another question. He strives to answer this in regard to allowing parturients to leave the bed early, Cesarean section for placenta prævia, extraperitoneal Cesarean section, vaginal methods for operations on the uterus, and the transverse incision (*Fascienquerschnitt*)—all popular in certain quarters in Germany. His conclusions are to the effect that the drawbacks of allowing women to get up before the seventh or eighth day outweigh

the benefits, and a retreat should be sounded. The advantages of a little early exercise can be obtained without leaving the bed. Cesarean section as a systematic method of managing placenta prævia is another evil which should be abandoned, he argues, as also the tendency to too exclusive use of the vaginal route. The by-injuries with vaginal operations are increasing in number, as, for example, the case of the woman whose sterility it was sought to cure by a salpingostomy; during this there was so much hemorrhage that the uterus had to be removed to arrest it. Dührssen's mortality in 441 vaginal operations was 13, while Krönig's was only 2 in 485 abdominal operations. The transverse incision is also proving unsatisfactory on account of the difficulty of restoring anatomic conditions afterward, as he shows by statistics from various clinics. Here, too, he declares, a retreat should be sounded. The enthusiasm for extraperitoneal Cesarean section has also subsided as it has been shown that it is not suited any better than the classic technic for suspicious cases. So of all this boasted progress nothing, he declares, has stood the test of time.

144 *Formation of Specific Antibodies and Fixation of Complement in Malaria. L. Ferrannini.
145 *Possible Cause of Error in Hydrostatic Test of Infant's Lung. A. Cevidalli.

144. **Fixation of Complement in Malaria.**—Ferrannini has been applying the complement-fixation test in malaria with extracts of malarial spleens for the antigen. The findings were constantly negative, and the negative findings of other investigators with different technics all apparently confirm the fact that malarial infection does not induce the production of antibodies. This confirms the clinical experience that an attack of malaria does not confer immunity; there is no production of agglutinins or precipitins. This explains the difficulty in radically curing the disease and the susceptibility to subsequent attacks although it is possible that a racial immunity may be gradually developing. He is inclined to suspect possibly latent syphilis in the positive findings with the Wassermann test reported by DeBlasi in 52 per cent. of his malarial patients examined and by Boehm in about 30 per cent.

145. **Hydrostatic Test of Infant's Lung.**—Cevidalli reports actual experiences which demonstrate that if the fetus gets any of the amniotic fluid in its lungs, the sebaceous smegma in the fluid is liable to make the lung float whether the child has breathed or not.

146 *Toothache in the Toothless. (Tandsmerter hos Tandlose.) M. Melchior.

146. **Toothache in the Toothless.**—Melchior warns against ascribing to the teeth what may be neuralgia from pressure on the nerve by some minute focus in the jaw. Or the trouble may be a reflex neuralgia from constipation, uterine disease, etc. In one patient, the "toothache" had persisted for a long time involving the upper jaw on both sides and persisting after all the upper teeth had been extracted. On suspicion of syphilis, potassium iodid was then given when the pain soon entirely subsided. Careful study of the case, especially noting the definite point where the pain begins, may point to the exact site of the hidden causal lesion.

CHRONIC URETHRITIS AND CHRONIC URETERITIS CAUSED BY TONSILLITIS *

GUY L. HUNNER, M.D.
Associate in Gynecology, Johns Hopkins University
BALTIMORE

The tonsils have been made the scapegoat for so many human ills that one hesitates to bring another charge against them. For eighteen months past, since having my attention directed to the possible relationship between tonsillitis and certain cases of chronic urethritis and chronic ureteritis, the evidence has been accumulating with such force that I feel justified in drawing up the indictment and ask that the problem be taken under advisement and judgment passed on it after experience may have justified or negatived my claims.

In a comparatively recent paper, Rosenheim[1] has reviewed the literature and found the following list of *ailments ascribed in certain cases to tonsillar infection*: aneurysm, appendicitis, erysipelas, and a number of other skin manifestations, meningitis, iritis, pleuritis, pericarditis, pneumonia, paraplegia and strabismus, parotitis, nephritis, osteomyelitis, phlegmon of the lower extremities, oophoritis and orchitis, septicemia, typhoid beginning with an angina, and tuberculosis.

It is only natural that we should look on such a list with some mental reservations, but no intelligent physician of to-day will deny that the infections and toxins of tonsillitis have an important causal relationship to many forms of rheumatism.

Those who have worked with the diseases of the urinary organs in women have for a number of years been familiar with the so-called rheumatic urethritis. In using this term I wish to exclude the old text-book application, for undoubtedly most cases of chronic granular urethritis are due to old gonorrheal infection, and our text-books have included these under the term "rheumatic." But we have seen many cases in which gonorrhea could be ruled out to a practical certainty and for which we have been at a loss for the etiologic factor. This is particularly true in the cases of respectable unmarried women who have a persistent urethritis and have intact hymen and very little probability of ever having contracted gonorrhea. Some of these chronic urethritides are associated with vulvitis and I have been inclined to class some of them as traumatic infections due to onanism. We see rare cases of cystitis and urethritis following immediately after marriage in which gonorrhea can be ruled out, and we find the infecting agent to be the colon bacillus or some other microorganism. These are undoubtedly traumatic infections. Theoretically a few of our chronic urethritis cases might be classed as auto-infections, because of the very short urethra and the myriads of bacilli and cocci normally inhabiting the region of the external urethral orifice.

If we rule out these possible auto-infections, gonorrhea, and trauma and infection from childbirth, coitus and onanism, we still have left a not inconsiderable proportion of our chronic urethritis cases for which we have heretofore been at a loss to explain the origin, and we have generally classed them as rheumatic urethritis. As a matter of fact most of these patients have suffered from some form of rheumatism and the local urethral treatment is more effective if the patient is given simultaneous internal antirheumatic treatment.

My experience with these cases is that they generally respond to local treatment more quickly than the chronic gonorrheal cases (although there are numerous exceptions to this rule), and as a rule they relapse within a *few weeks or possibly months after the patients think* themselves well.

I am not certain that there is any speculum picture to differentiate the rheumatic from the gonorrheal cases, but I am under the impression that we will find, in many of the rheumatic cases, most inflammation about the inner third of the urethra, while we all know that in the gonorrheal cases the inflammation persists longest about the outer third of the urethra, where are located most of the urethral crypts and glands.

ILLUSTRATIVE CASES

Case 1.—My attention was first called to the possible relationship between the tonsils and the urethra by a patient whom I had been treating for chronic urethritis from December, 1908, to May, 1909. During this five months I had been treating the urethra once or twice a week by dilating with Hegar dilators and mopping the urethra with either 3 or 10 per cent. silver solution. During this time I had on one occasion prescribed a gargle for a sore throat. May 20 the patient asked me why her throat should always be irritated immediately after I made the silver application. This sore throat lasted as long as the urethral reaction was active, about twenty-four hours if I used the 3 per cent. silver, and as long as three days after the 10 per cent. silver. She said that she had noticed this phenomenon for some time and she had also noticed that her throat and urethral irritation always seemed to be aggravated in damp weather. I examined her throat and found that the tonsils were large and presented numerous crypts over the surface. I referred her to Dr. T. Chew Worthington who reported as follows: "The tonsils, while very deep and buried between the pillars, are much larger than they appear, and show evidence of frequent inflammation, and I believe that they are largely responsible for the patient's rheumatic trouble; but I do not know to what extent they may cause the urethritis." They were so riddled by necrotic foci that it was impossible to remove them except by morcellement. I saw the patient three times within the next two months and her symptoms had rapidly disappeared, although she was having some discomfort at times and the urethra showed some granulations over its inner half.

---

* Read before the meeting of the Southern Surgical and Gynecological Association at Nashville, Tenn., Dec. 13, 1910.

[1] Rosenheim: The Tonsillar Ring and the Paranasal Sinuses as Portals of Entry of Infectious Diseases, Bull. Johns Hopkins Hosp., November, 1908, xix, 338.

One can scarcely appreciate the marvelous change in this patient without knowing the details of her history and having treated her as I did for five months without appreciable permanent relief. She was a single woman, a seamstress, 42 years of age and had entered the menopause two years previously. She remembers one attack of inflammatory rheumatism when 25. She had had bladder irritation at times for eight years, this occurring only once or twice a year up to within two years ago, since which time she had had no relief. She complained of great frequency and of sharp stinging pain in the neck of the bladder while voiding. She was often afraid to leave the house because of her inability to control the bladder. In addition to the local symptoms she had pain in the right groin and great discomfort and soreness across the entire lower abdomen. She often had a sinking feeling, nausea, and a desire to void if she made a misstep while walking, or if she rocked in a chair, or drove over a rough road, or rode in the street car. Bimanual examination of the pelvis and lower abdomen elicited considerable muscle spasm, and because of this and her very indefinite symptoms I was led on several occasions to think of the possibility of chronic appendicitis. Pelvic examination and high rectal examination were negative. Palpation over the urethra caused reflex pain in the bladder region. The most striking feature of her examination was the fact that on distention of the urethra when injecting the 10 per cent. cocain solution preparatory to the urethral treatment the patient always complained that I caused her typical abdominal pains reaching as high as the umbilicus, and a feeling of nausea. It was this one persistent and consistent complaint of the patient that soon led me to cease thinking of a chronic appendicitis. It well illustrates also a dictum that I have given my students for a number of years, viz., when dealing with any obscure abdominal complaint located below the level of the umbilicus, never to overlook an examination of the urethra.

Within two months after the tonsils were removed, the preliminary distention of the urethra with cocain did not cause abdominal discomfort. The spontaneous abdominal discomfort had disappeared and the only symptom was a slight local irritation in the urethra.

At my request the patient came to my office on Dec. 1, 1910. She had been practically well for the intervening fourteen months. On some days she is conscious of a slight uneasiness in the bladder, but she often holds the urine all day. She has never had the soreness across the hypogastrium nor the nausea and sinking attacks. Riding over a rough road or jarring from any cause does not affect her. While formerly she never dared sit in a draft, she now does not consider such matters. The anxious, harassed expression of the face has disappeared and she claims to be in perfect health. Cystoscopic examination shows the urethral mucous membrane to be normal.

Case 2.—In February, 1909, Dr. A. I. Miller, of Brattleboro, Vt., sent me a Miss B., aged 35, who had been complaining of bladder trouble since an operation for uterine displacement in October, 1907. The patient was in an extremely nervous condition and examination showed the urethra to be contracted throughout its length and to have a very granular, red mucosa. She remained at the Johns Hopkins Hospital for six weeks, being treated for her nervousness and having the urethra treated about once a week. Within six weeks the urethra easily took a number 12 Hegar (12 mm.) dilator and its mucosa was normal-looking. Fearing a return of her trouble, the patient did not go home on dismissal from the hospital and her fears were well founded, for her urethral irritation returned in a few days. In May the patient was complaining of joint trouble for the first time and was placed on aspirin treatment which helped her joints and seemed to help the urethra. After my experience with the first case and in view of her rheumatic manifestations I examined the patient's throat and found that she had large tonsils. She refused to have these operated on until Dec. 23, 1909, when Dr. H. C. Davis removed her tonsils, finding them in much the same condition as those found in the first patient. The patient's urethra answered more readily to the treatment after the removal of the tonsils, but for about seven months there was a small area at the base of the right tonsil which became much irritated at times, and the patient was then very likely to complain of rheumatism in her knees and of the urethral irritation. After the spot in the right fauces was repeatedly touched with 10 per cent. silver solution and the urethra dilated and touched with solution of the same strength the patient has finally made an apparent complete recovery For four months past the irritation has been almost completely absent and the urethral mucosa, examined on a number of occasions, has remained normal.

Case 3.—Miss W., aged 48, admitted to the Johns Hopkins Hospital Oct. 10, 1901, complained of bladder trouble, indigestion, and nervousness. The menopause occurred four months previously. As a child the patient had measles and diphtheria She had pneumonia when 18 and suffered with neuralgia and headaches. Six years previously she had an infection of the middle ear from her throat and the ear drum ruptured and drained freely. Hearing had been impaired since and she had occasional attacks of earache. She had hay fever every summer for years.

Four years ago, or in July, 1897, she first had bladder trouble as a frequency of voiding with intense pain, and the urine contained blood and mucus for several days. The pain and frequency lasted three months.

In the following four years she had had about two attacks a year usually lasting about two weeks. In January, 1901 she was confined to her room for one week with an attack and since then had constantly felt that an attack was impending. Her present attack came on five weeks prior to admission It began with intense pain which prevented sleep. The pain was more severe on voiding. She passed some blood.

Examination revealed a normal bladder and a severe urethritis located in the inner third of the urethra.

A few treatments resulted in an apparently perfect cure.

She was again admitted to the Johns Hopkins Hospita March 14, 1910. After leaving the hospital in 1901 the patient was free from urinary symptoms for two years. Her symptoms of frequency and pain then began and for two years she had occasional loss of control of the urine. In 1905 she had a severe attack of typhoid fever with a long, slow convalescence, and now for five years she has had almost constant bladder trouble. For the past year her symptoms have been worse and she generally wears a napkin because of complete incontinence.

I examined the patient March 16, 1910, and found a specimen of urine drawn by the catheter clear. After applying 10 per cent. cocain solution and placing the patient in the knee breast posture the urethra was first sounded with a 5 mm Hegar dilator. This broke down what felt like a soft scar tissue obstruction at or near the internal urethral orifice. No further obstruction was felt in dilating up to a 10 mm. Hegar dilator.

The bladder was normal, but the urine settled in the vertex was bloody. This blood was found to be flowing from the anterior aspect of the internal sphincter region, probably from the obstruction felt to give way under the No. 5 Hegar.

The patient improved rapidly under the treatment by dilatation and applications of 3 per cent. silver solution.

After three weeks she complained of an attack of sore throat and examination showed enlarged and inflamed tonsils. These were partially removed with the tonsillotome April 22, and the patient was soon discharged. In answer to a letter in November she wrote in part as follows: "I am stronger than when I went to the hospital last March, but the bladder trouble is no better; in fact, it is so bad I very seldom leave home. I cannot see that the removal of the tonsils has helped me at all. I have just as much rheumatism and sneeze very much each day; in fact, more than I ever did."

If my theory is tenable this is just the result one would expect from partial removal of the tonsils by the tonsillotome The patient's reference to the persistent sneezing and her "nasal" method of talking make me think that she has paranasal sinus infection as well and she has been advised to return for more complete attention to the tonsils and air passages.

Case 4.—Miss H., aged 26, consulted me July 14, 1910. For about three years the patient had had bladder symptoms more or less constant, but exaggerated with overexertion, and particularly on damp days. When at its worst there was almost a constant desire to void. She did not consider the distress a pain nor a severe burning, but said it was more of a nagging. For the previous five or six months there had been a peculiar tired feeling in the right pelvis and the patient worried for fear that some serious condition was developing.

The patient had quinsy twice as a child and she was bothered a great deal with her throat. She had a severe attack of quinsy last winter and after four days the abscess ruptured. She has not had rheumatism. Examination of the heart revealed a soft systolic murmur over the mitral region and an accentuated second sound at the base. Both tonsils were enlarged. The bladder urine was normal. The urethra was very tender on introduction of the catheter and on examination it was found to be granular and reddened throughout its length.

The urethra was dilated and swabbed with 3 per cent. silver solution July 14 and July 21. The patient was sent to Dr. Sanger, who removed the tonsils early in August. He reported the right tonsil as badly diseased. Two weeks after the tonsillectomy I found the urethral mucosa less tender and less inflamed. I gave the third treatment and the patient left the city to take a position as school teacher. I have heard indirectly that she is greatly improved in health, and as the urethra seemed to be the only point of complaint I conclude that this must be improved.

SUMMARY OF CASES

To review the evidence briefly in these four cases:

In Case 1, the patient, as long as she could remember, had a tendency to "catch cold" easily and had to avoid drafts. She had an attack of acute inflammatory rheumatism involving the joints of the left side seventeen years previously. For eight years she had had attacks of bladder trouble and abdominal discomfort which for the previous two years had kept her in almost constant agony and had often kept her housed because of the inability to control the urine. Five months of regular treatment about once a week had made but little impression on her urethral and reflex abdominal symptoms. After the tonsils were removed three treatments in the next two months resulted in a cessation of practically all her symptoms and she often retained the urine an entire day. This cure has lasted for fourteen months.

In Case 2 the patient had had constant bladder symptoms for over two years, the disturbed nights and diurnal irritation making of her almost a nervous wreck. Bladder and urethral treatments had been without permanent effect. Treatment of the urethra for six weeks while she was in bed resulted in an apparent cure, but one week after leaving the hospital the symptoms returned and the urethra looked as inflamed as ever. Months of treatment, with the patient boarding in the city and having almost complete rest, gave occasional periods of one to two weeks of improvement in the symptoms. After the tonsils were removed there was ~~one~~ inflamed area in the base of the right tonsil region which for seven months gave occasional exacerbations of sore throat accompanied by pain and tenderness in the knee-joints and an exaggeration of the urethral symptoms. For the four months following treatment the patient's throat gave but few symptoms and the urethra was well as regards symptoms and appearance. After the tonsil operation the patient took a position as matron of a woman's dispensary, her duties ranging from bookkeeper to scrub woman, so that her improved health cannot be ascribed in any way to opportunities for rest.

In Case 3, when first admitted to the hospital in 1901 the patient had been suffering for four years with recurring attacks of bladder trouble. A few treatments of the urethra gave complete relief. For two years she had approximate health and then for seven years her bladder trouble had been growing worse until she had to depend permanently on a pad for catching the urine. Again a few urethral treatments seemed to relieve her condition perfectly. Her tonsils were then shaved off with a tonsillotome and within a few weeks her symptoms became as bad as ever.

In Case 4 the patient had complained of bladder trouble for three years and gave a clear history of tonsillar trouble since childhood, with three attacks of quinsy. In her case the tonsils were removed after two urethral treatments, so that we have not the striking demonstration, as in the other three cases, of the futility of urethral treatments while the tonsils remain.

I realize that these four cases of chronic urethritis are too few in number and of too recent occurrence to serve as a basis for reliable conclusions. The evidence here set forth, however, is sufficient to warrant a more careful study of our chronic urethritis cases, for if we can relieve permanently only a small proportion of these chronic sufferers by a comparatively simple operation, we will have made an important advance in therapeutics.

Since I have been on the lookout for these cases I have added seven others to my list which probably belong to this class. Some of the patients have been under my care intermittently for several years and it is only because they have chanced to return during the past few months that they are mentioned in this report.

Two are worthy of an extended report.

Case 5.—Mrs. M., of St. Paul, telephoned me from New York in September of this year asking for an office appointment, stating that she had been my patient three years ago. On looking up her history I made a mental prediction that diseased tonsils would be found on another examination.

The history taken on her first visit in May, 1907, was as follows: About June, 1906, the patient developed rheumatism in the right knee, for which she went to Mount Clemens, and while under treatment there the trouble involved the joints of the right hand and the third finger of the left hand. About this same time she began to have "bladder trouble." This developed gradually as a scalding or burning, which was more likely to come on ten or fifteen minutes after voiding, and which she thought was in the urethra rather than in the bladder. She had no trouble at night; the aggravation had been more persistent for the last four months, occurring every day or every other day and preventing her from walking or taking much exercise. On further inquiry regarding her rheumatism she said that in 1891 she had rheumatism in the right shoulder and arm and in 1903 she was at the French Lick Springs for rheumatism in the right knee. When she first consulted me she had just spent six weeks at the Arkansas Hot Springs for rheumatism in her hands.

The urine on examination at this first visit was normal; the bladder was somewhat reddened about the trigonum, and the urethra was narrowed and showed a granular red mucosa throughout its length. I made a diagnosis of chronic granular urethritis of rheumatic origin. After two treatments consisting in the dilatation of the urethra and the application of 3 per cent. silver solution on the first visit and of the 6 per cent. silver solution on the second visit, the patient was obliged to return home. I sent instructions to her physician in St. Paul concerning further treatment.

On her return in September, 1910, the patient stated that she had been fairly well and had taken no further treatment. She had recently had considerable anxiety, was in bad physical condition and her urethral trouble had returned. I examined the urethra through the Kelly cystoscope without first disturbing it with the Hegar dilators, and found that the granular redness was confined to the urethral sphincter and to the mucosa of the inner third of the urethra. In view of my recent experience I quizzed her more closely and found that she had her first bladder symptoms when 16 years of age; that she often had a sore throat as a child, but did not remember having tonsillitis. This past winter she had considerable "rheumatic sore throat." I examined her throat and found much congestion about the fauces; the tonsils were considerably enlarged and had deep crypts over the surface, these being free from white deposits at the time of my examination.

I sent her to a laryngologist who considered that her tonsils were undoubtedly a causative factor in the rheumatism.

CASE 6.—Mrs. R., aged 32, mother of three children, the youngest 4 years old, was referred by Dr. Gaver of Mount Airy and admitted to the Church Home in June, 1909. She had had bladder trouble for the previous three years with only brief intervals of freedom from pain. At times she had been in bed a week because of agonizing pain. There had also been pain in the right flank region and the patient was then wearing a plaster because of the pain and weakness in this region. I first thought, on taking her history in my office, that she probably had tuberculosis of the right kidney. The urine catheterized from the bladder contained many epithelial cells, leukocytes and red blood-corpuscles. Examination for tubercle bacilli was negative, but the urine contained many cocci, some arranged in pairs, suggestive of gonococci; none could be found, however, in the pus-cells. After a day of rest in the hospital cystoscopy was done and the urethra was dilated with difficulty, there being a stricture about half way in and another at the internal orifice. The trigonum was of a deep red hue and apparently swollen; the bladder mucosa was everywhere traversed by congested vessels. Both ureteral orifices were red but neither showed particular evidence of disease. The right ureter was catheterized with a No. 5 wax-tipped bougie, which returned without scratch-marks. The urine from the right kidney was normal. After a few days' observation I made a diagnosis of appendicitis and a large congested appendix was removed. During four weeks in the hospital the patient received treatment for her cystitis and the urine became normal.

I have given this patient many urethral treatments in the eighteen months previous to this report. The stricture at the inner orifice still persists and she still had occasional attacks of urethral symptoms accompanied by granular reddening of the mucosa.

The patient had her tonsils removed about 1907 but she did not remember the chronologic sequence of her bladder and tonsillar trouble. She still has considerable throat trouble and examination shows a mass of tonsillar tissue on the right side.

The possible relationship between tonsillitis and ureteritis has been brought to my attention only recently, the two patients possibly belonging to this class still being under observation and only one of them having had her tonsils removed.

In September, 1910, Dr. Herman F. Derge of Eau Claire, Wis., sent me a patient 26 years old, who had the following history:

CASE 7.—Six or seven years previously the patient had an attack of pneumonia, which was followed by tonsillitis and rheumatism. At that time her tonsils were treated with the cautery. Soon after this she began to have attacks of pain in the left flank region. At first these attacks occurred every two or three months and the patient would lie down and flex the left leg for an hour or two until the attack disappeared. Her attacks gradually became worse, but she never had any nausea or vomiting with the attacks until the spring of 1910.

In February, 1910, she had an attack of tonsillitis and rheumatism, followed by similar attacks in March and April. After this the attacks of pain in her side became much more severe and were accompanied by nausea and vomiting. Dr. Derge wrote me in August that he had had the patient under observation in the hospital for four weeks, and said: "During this time her temperature has always been normal and the pulse has ranged between 72 and 96. For the first three weeks the urine contained constantly 1 gm. of albumin, pus cells, some red blood-corpuscles and a small rather thick bacillus. On two separate occasions I have examined the urine for tubercle bacilli but have found none. I have also cystoscoped her twice and on each occasion failed to get a catheter into the left ureter. The bladder itself looks perfectly normal and she has had no vesical symptoms. For the past week the urine has looked perfectly normal, there being neither albumin nor pus cells present and she excretes on an average 2 liters a day. Yesterday she had another attack of pain in the left side, was nauseated and vomited."

On her arrival in Baltimore the patient looked exceedingly ill. She had been having an attack the previous night, with much nausea and vomiting. I found a mass in the left kidney region projecting about 4 cm. below the costal margin. This was very tender and on palpation of the pelvic brim in the region of the ureter considerable pain was caused. Urine catheterized from the bladder was acid, showed a specific gravity of 1028 and contained a slight amount, about 0.1 per cent. of albumin. The microscope showed many epithelial cells and an occasional red blood-corpuscle. Three good radiographs of the kidney, ureter, and vesical regions, respectively, were negative.

After a few days' rest in bed, with frequent injections o morphin to control her pain, I made an unsuccessful attempt to catheterize her left ureter. Nine days after her arrival Dr. Sanger removed her tonsils and about ten days later I again failed to catheterize the ureter.

For two weeks after the removal of the tonsils the patien had about the same symptoms in the kidney region, th attacks being more severe if anything. After this the attack seemed to be less frequent and decidedly less severe, the patien was allowed to take walks and drives and go to the theater thus leading about a normal life, and her attacks of pai which occurred every two or three days were aborted wit one injection of ¼ grain of morphin, whereas her forme attacks had required from one to three ¼-grain injections.

Of course one cannot expect a disappearance of the sca tissue involving the ureter after the removal of the tonsils an I should explain the improvement in her condition as due t the removal of the toxins which had caused the repeate inflammatory attacks in the ureteral mucosa.

After waiting two months and being unable to dilate th stricture from the bladder end I operated to dilate the stricture from above. Through a left rectus incision the peritoneum was pushed medianward until the ovarian vessels an ureter were found running parallel in the peritoneum. Thi exposed the iliac vessels on the pelvic brim and the roun ligament covered with peritoneum near its entry to th internal ring. It also gave excellent exposure of the bladde By blunt finger dissection the ureter was easily followed dow to the point where it ran under the uterine vessels. A poin was selected on the ureter low enough down so that in cas the stricture could not be dilated the ureter could be cu across and implanted into the bladder. At this point, abou 5 cm. above the crossing of the uterine vessels, the urete was opened lengthwise and I had no trouble in passing gum elastic filiforms, and finally a large follower 7 mm. in diamete into the bladder. A renal catheter was then passed into th bladder and its distal end was passed almost up to the kidney The ureter was closed with fine catgut and a small finge drain was carried down into the ureter wound. After th closure of the abdominal wound the table was elevated an through a Kelly cystoscope the pointed end of the rena catheter which had been passed into the bladder was located grasped with the alligator forceps and drawn out through th urethra. The pointed end was cut off and the catheter wa fastened to the thigh by adhesive strap and through thi catheter the kidney was irrigated three times a day for fiv days with 1-10,000 silver nitrate solution. The bladder wa given a similar irrigation once a day.

Three weeks after the operation the patient was walking about the hospital. She had no sign or symptom of returning trouble in the left kidney. A suggestive feature in this case, as in case of urethritis, was that she had a sore throat and hoarseness after each attempt to catheterize the ureter, such treatment being followed by my routine swabbing of the urethra with 3 per cent. silver solution.

CASE 8.—The second case of stricture of the ureter was that of a colored woman, aged 48, who had been under my care in the cystoscopic dispensary for several weeks. She began to have bladder trouble in May, 1910. She complained of a frequency and burning and thought she had caught cold in the bladder. For two years she had had mild attacks of pain in the right kidney region. These occurred from one to three weeks apart and she had no discomfort in the side between the attacks. Since the bladder trouble began in May she thought that the attacks of pain in the side had been more frequent and more severe.

About the same time that the pain began in the side she had a bad attack of inflammatory rheumatism in the left knee. This lasted all winter. Off and on for three or four winters she had rheumatism under the left shoulder blade and in the cervical vertebræ, this at times keeping her from work. She noticed for two years previously that she caught cold very easily and had a sore throat even in the summer time.

Examination of the urine catheterized from the bladder showed a moderate number of pus-cells. The right ureteral orifice was slightly inflamed, presenting such a picture as one sometimes observes when a stone lies low in the ureter. On four different weekly visits I attempted to pass a wax-tipped catheter to the right kidney, being successful only on the second visit. The wax tip returned without scratch marks. On injection of the kidney pelvis her pain-phenomena in the right kidney region were imitated. The pelvis was but slightly dilated, holding but 12 c.c. of fluid. The point of obstruction to the renal catheter was located about 3 cm. from the bladder orifice of the ureter. *X*-ray examination of this region was negative.

The patient's tonsils were both considerably enlarged and she has promised to have them removed.

On meeting a stricture in the ureter and looking for the cause one thinks, in the order of their frequency, of stone, tuberculosis, gonorrheal infection, and then of pelvic inflammatory disease, appendicitis, and pelvic or abdominal tumors. We sometimes meet an obstruction to the catheter which is not met on another occasion and we conclude that the obstruction was probably peristaltic in character. Some obstructions are probably caused by unusual kinks in the ureter following inflammatory displacements. Most of the ureteral stricture or obstruction causes, such a stone, tuberculosis, and periureteral tumors, are easily differentiated. There are not a few strictures about the lower end of the ureter for which we have been unable to find an etiologic factor. I have been inclined to think that some of these may represent a healed focus of tuberculosis, some an infiltration of scar tissue about a stone which has later been dislodged and passed, and a more probable supposition to my mind has been that a gonorrheal infection of the bladder may have resulted in infectious material or toxins being carried in the periureteral lymphatics, causing a focus of inflammation in the ureter near the bladder. I have not been able to prove any of these suppositions in the case of ureteral strictures, but I am inclined to believe that this newer theory of tonsillar infections or toxins giving rise to ureteral stricture may be found to apply to some cases for the causation of which we would otherwise be in the dark. The futility of treatment by dilatation in such cases without removal of the tonsils is apparent.

I am not familiar with male genito-urinary work, but am told that many cases of chronic urethritis, trigonitis, inflammation of the verumontanum and other portions of the posterior tract cannot be traced to a gonorrheal infection. Dr. Geraghty of the Johns Hopkins Hospital tells me that he has seen cases of acute prostatitis with abscess formation which followed during or immediately after a tonsillitis. With such facts in hand it seems not improbable that some cases of chronic urethritis associated with chronic prostatitis may have their origin from tonsillar infections or toxins.

2305 St. Paul Street.

TWO CASES OF HUNTINGTON'S CHOREA WITH SPINAL FLUID FINDINGS

W. F. LORENZ, M.D.
MENDOTA, WIS.

Chronic progressive chorea associated with mental enfeeblement occurring during adult life, first fully described by Huntington in 1872, seems far more prevalent in the Middle West than in the East. There were but two cases of this type among the 2,436 admissions to Manhattan State Hospital[1] during 1909 and 1910. If this can be taken as an indication of the prevalency of Huntington's chorea in the East, it will be seen that it is quite low when compared to the number admitted at Kankakee, Illinois, and the Wisconsin State Hospital during the same period. The combined admission rate of these two last-named hospitals approximately equals that of the Manhattan State Hospital. At Kankakee there were two patients admitted[2] and five at the Wisconsin State Hospital. It will also be recalled that Hamilton's[3] twenty-seven cases were all taken from the Middle West.

The following two cases seem especially worthy of report in that the hereditary transmission, mental involvement and well marked chorea offer a picture classical of this disorder.

CASE 1.—J. R., male, farmer, widower, was admitted to the Wisconsin State Hospital Oct. 15, 1910.

Family History.—The family history showed the maternal grandmother to have been choreic, although nothing definite as to mental symptoms could be obtained. Her death occurred at 56 and the cause given was "nervous trouble." The other grandparents died of old age. The patient's mother was admitted to this hospital in 1891, suffering from chorea and was described as being "demented." She was transferred to a county hospital where she died. The father died at 67 of "paralysis." There were eight children, of whom the patient was the oldest of five brothers. Two sisters died in infancy of unknown cause. The sister living is said to have chorea, which developed after childbirth, and is a patient at a state hospital in Washington. The youngest brother is said to be "nervous."

Personal History and Present Illness.—The patient was born June 12, 1869. Nothing of note occurred in his early life. He attended a country school and was thought to be unusually bright. After leaving school, he worked on a farm; married in 1900; wife died of typhoid fever in 1907; one child, a girl, at present 9 years old, is normal.

In 1904, twitchings were first noticed, although neither the brother nor the patient know what part first became involved. They described the twitchings as being general. These twitchings gradually became more pronounced, yet the patient continued at his work as a farmer, and was said to have been industrious and thoroughly capable. No mental symptoms were noticed until about one week previous to admission, when on returning from the field where he had been working, the patient complained bitterly that some one had strewn blood all about the field. He was very excitable and soon complained that he was covered with blood; that some one was dragging bloody ropes about the room. He became very much frightened, tried to lock himself in a room and began crying out at the top of his voice. He was sent to a jail where he remained two days, and then transferred to the state hospital at Mendota.

---

[3] Hamilton, A. S.: Am. Jour. Insanity, lxv, 3

On admission the patient was in a very apprehensive state, shouting almost continually, "Take them away. They are trying to kill me," etc. He pressed himself against the wall of the room, and when approached would strike out blindly. This apprehensive excitement, with very evident hallucinosis, subsided after forty-eight hours and the patient gradually became accessible. The auditory hallucinations were now readily spoken of by the patient, and continued another four days, gradually becoming less and less marked. During this time he complained that the "voices" threatened to kill him and several times he asked the examiner when he was to be executed. Within ten days after admission, the hallucinosis had entirely disappeared and the patient became readily accessible for both mental and physical examination.

Mental Symptom-Complex.—A vivid auditory and visual hallucinosis, accompanied by marked apprehension lasted for five days, and auditory hallucinations persisted for another four days (threatening voices). On return to a quiet state there was a definite amnesia for the delirious episode, with a mild intellectual deterioration, poor memory for dates and poor retention, but good insight for the hallucinosis.

Physical Symptoms.—The most striking features were the gait, the choreic movements and the very peculiar facial expression. The patient was of swarthy type, height 5 feet 6 inches, weight 150 pounds, hair slightly tinged with gray, no physical stigmata of degeneration. The chorea was general; the movements were rather slow and deliberate, though quite extensive, as if the muscles involved had acted to their full extent. All the muscles of expression showed this condition—the occipito-frontalis especially: the lips were alternately drawn back and then puckered, drawn to one side and then the other. There was a constant clicking of the tongue; the mouth opened and closed; the eyes could not be held steadily in one position, but moved slowly from one side to the other. The subptosis lent a very peculiar expression to them, as if the individual were intoxicated. There was present a persistent, irregular, spasmodic cough, with almost constant moaning and groaning. The arms and shoulders swayed about, the hands opening, closing and twisting; the trunk swayed forward, backward and to the side. In station, one leg would suddenly shuffle forward, to the side or backward; the gait was a peculiar skipping, swaying, dance-like activity. The toes were seen to flex, extend and spread themselves. The patient could hold a pencil and would attempt to write, although the specimen was hardly legible. While making this effort, the movements of the other parts seemed exaggerated. The muscles were well developed, powerful and firm, with a very noticeable increase of tone. The superficial reflexes were all active; the deep, very decidedly exaggerated. The pupils were equal and active to both light and accommodation. The speech was at all times very harsh, thick and interrupted by spasmodic cough; at times completely aphonic. No sensory disturbances could be made out. The pulse was irregular; at times seemed to pause, followed by a number of slighter pulsations in rapid order, until again assuming its regular rhythm. This would occur four or five times in a minute. The patient sometimes experienced difficulty in starting the act of urination. Deglutition was interfered with. During sleep the movements ceased, although they recurred immediately on awakening.

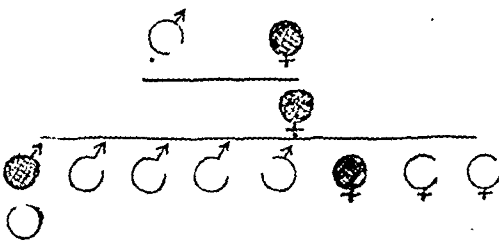
Case 2.—W. P., male, single, farmer, admitted to the Wisconsin State Hospital Oct. 28, 1910.

Family History.—The paternal grandfather suffered from chorea, and was said to have been mentally afflicted, though never committed. Of four boys and two girls in the succeeding generation, the oldest (father of the patient) developed chorea at the age of 55, became very forgetful and simple, and died of a strangulated hernia at 60. The youngest of these brothers developed chorea at about 50, became insane and died in an asylum. The next succeeding generation, that of the patient, comprised four boys, of whom the patient was the oldest, and one girl. Of these the patient was the only one thus far who showed symptoms of chorea, although the youngest brother, aged 32, was said to be decidedly nervous.

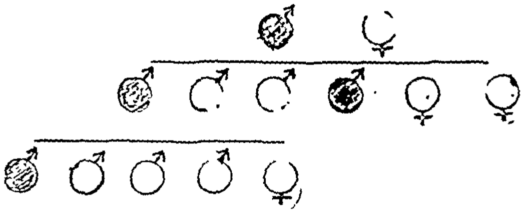
Personal History and Present Illness.—The patient was born in 1855. Nothing abnormal occurred during infancy or childhood and he was said to have been of average intelligence, getting along very well at school. He began farming at about 20 and continued at this until the onset of his mental symptoms. At the age of 7 he developed an abscess of the right leg, which discharged slightly though persistently for fifteen years. He was always very temperate in his habits and never had any venereal infection.

At the age of 38, mental failure was first noticed. This was in the nature of sudden outbursts of anger and a change in the patient's disposition. He was described as having become "preoccupied." This became more noticeable, and his memory was said to have become poor during the succeeding five or six years. The patient also began expressing peculiar ideas concerning his financial status; expressed himself as wishing to get rich quickly, laying great stress on a rather simple and not very serviceable combination garden tool, which he invented. He maintained that, if this could be properly exploited, it would result in great wealth, and he became very angry with his relatives when they interfered with his attempt to sell his property in order to capitalize this venture. He also had very unpractical ideas concerning the development and sale of real estate; would collect and answer every advertisement he could get hold of; finally became so irritable that he could no longer be taken care of at home. About five years previous to admission, at the age of 50, the motor symptoms first became noticeable. These were described as a "jerkiness," at first involving the hands and arms, gradually becoming more marked and general. During the last two years before admission the mental dulness became very pronounced.

Hereditary Transmission in Case 1.



Hereditary Transmission in Case 2.



Mental Symptom-Complex.—A general mental deterioration; gross memory defects; very meager knowledge of the events of the last five or ten years; retention *nil;* mildly euphoric; a few absurdly expansive ideas concerning personal capabilities; no insight.

Physical Symptoms.—The face presented a very peculiar, sleepy appearance without sign of emotion. The chorea was very noticeable, involving the muscles of the neck, shoulders, arms and hands mostly. The head was extended backward, or bowed forward, or either of these combined with rotation or lateral movement. The mouth was drawn to one side or the other, the shoulders hunched frequently and equally, together or alone. The arms moved forward or backward, forearms flexed and the fingers moved about. All of these movements were quite slow and of irregular frequency, although rarely was there any part unaffected. The legs showed relatively little, save when walking, when the gait was a peculiar, straddling, shuffling, swaying locomotion. The muscles were well developed, firm and of a good tone. The eyes were unaffected; pupils equal and active to both light and accommodation. A slight peripheral arteriosclerosis was present; pulse regular; soft systolic murmur at the apex. Superficial reflexes were all active and the deep were markedly increased. Speech was very thick and difficult to understand. Writing was impossible. Movements ceased during sleep.

Lumbar Puncture.—Spinal fluid examinations were made in both cases, and are interesting in that both were negative, cytologically and chemically. The method of examination employed was that used by Dr. Bybee and myself in a series of spinal fluid examinations recently reported.[4]

Results of the Examination of Cerebrospinal Fluid

	Case 1	Case 2
Cells per cu. mm.	4	1
Small leukocytes	78 per cent.	76 per cent.
Plasma cells	16 per cent.	14 per cent.
Large lymphocytes	3 per cent.	2 per cent.
Polymorphonuclear leukocytes	1 per cent.	8 per cent.
Endothelial cells	0 per cent.	0 per cent.
Degenerate cells	2 per cent.	0 per cent.
Nonne and Appelt's, first phase	Faint.	Faint.
Nonne and Appelt's, second phase	Negative.	Negative.
Noguchi's butyric acid test	Negative.	Negative.
Reaction to Fehling's solution	Reduction.	Reduction.

These negative findings are especially interesting in view of the difference of opinion held as to the pathologic condition present in these cases. Certain observers have viewed the condition as an inflammatory lesion of the cortex and meninges, some going so far as to associate it with general paralysis. On the other hand, more recent writers have contended that the condition is one of neuroglia proliferation. In the case with autopsy findings reported by Rusk[5] the author favors the latter contention. It would seem to me that the negative pleocytosis found in the above cases would also tend to rule out the presence of an inflammatory condition of the cortex or meninges. Dunlap's[6] report and that of Raecke[7] agree as to the absences of an inflammatory condition.

A glance at the genealogic charts will show that the hereditary transmission in Case 1 occurred through the female members of the family until the patient's generation, while in Case 2 it was through the male members and the males were alone affected.

It will be observed that these two cases vary considerably in the mental symptoms which were present. Case 1 showed, I believe, the "confusional hallucinatory delirium" spoken of by Brower and Bannister,[8] also agreeing in many respects with the delirium, occurring in these cases, described by Clouston[9] many years ago. Both cases show a marked memory defect, although in Case 2 the mental enfeeblement is more general and more marked. This latter case likewise shows the expansive delusional formation spoken of by Osler[10] and others.

Voluntary effort had no effect on the movements in Case 2, although here so much mental dilapidation is present that very likely this effort was not made, or at least not sustained. In Case 1, the movements were momentarily controlled in that part in which volition was exerted, although at the expense of the other parts. This was observed by Hamilton[3] to occur frequently, and was evident in Case 1, when he attempted to write. The patient exerted himself to the extent that a noticeable perspiration occurred on his forehead and called forth the remark from him: "Gosh, Doc, this makes me sweat."

The hypertonicity of the muscles noticed in Hamilton's[3] cases was present to a considerable degree in Case 1 and appreciably so in the upper extremities of Case 2.

No precipitating cause was obtainable. Alcohol and syphilis were denied in both cases. One rather interesting fact is that the grandparents in both cases were said to have been natives of New York State.

In order of occurrence of mental and motor symptoms, Patient 1 showed a chorea for approximately five years before noticeable mental symptoms occurred, while, on the other hand, Patient 2 showed mental symptoms twelve years before the motor became manifest. In both cases the informants were able to give reliable information.

In conclusion I wish to express my indebtedness to Dr. Charles Gorst, superintendent of the Wisconsin State Hospital, for permitting the report of these two cases.

TRAUMATIC PSYCHOSES AND POST-TRAUMATIC PSYCHOPATHIC STATES

BERNARD GLUECK, M.D.
Junior Physician, Government Hospital for the Insane
WASHINGTON, D. C.

Various authors have attempted to establish a distinct clinical entity which could be termed traumatic psychosis, but a review of the cases reported in the literature shows that as yet we have not succeeded in attributing a distinct symptom-complex to this form of mental disorder. The only justification for grouping these cases under the heading of traumatic psychoses is their common etiologic factor, namely, trauma to the head. The degree and kind of injury are factors of some importance, and, as a general rule, only those injuries which produce an extensive, diffuse shaking up or shattering of the brain tissue, such as occurs in concussions or those which produce extensive pressure on the brain, will be followed by mental disturbances. A well-localized and circumscribed trauma to the brain is rarely followed by psychotic manifestations.

The general symptomatology of these cases varies greatly both in the time of occurrence and in the characteristic manifestations. The course of the disorder is also very variable, and it behooves one to be careful in rendering a prognosis in these cases. The cases which I am about to report in this paper have been selected because they illustrate the various forms and the variety of courses that this disease can take.

Kraepelin[1] in his work on psychiatry recognizes two forms of disturbance following trauma to the head, namely, a traumatic delirium and a traumatic feeblemindedness. His description of traumatic delirium does not vary very much from other delirious states, and simulates more the Korsakow's psychosis than any other mental disorder. This view is also shared by Calberlah,[2] who states that all these patients show the retrospective falsifications of memory and "confabulations"[3] so frequently seen in Korsakow's psychosis. This view, however, is denied by other writers on the subject and, as will be seen later, some of my cases showed nothing of this symptomatology.

---

[1] Kraepelin: Psychiatrie, eighth edition.
[2] Calberlah: Arch. f. Psychiat., xxxviii.
[3] This word is used by W. A. White in his Outlines of Psychiatry, by Paton in his Psychiatry, and by others, in the sense of the narration, without intent to deceive, of fictitious experiences, in the truth of which the narrator fully believes.

According to Kraepelin, the immediate results following concussion are a more or less complete clouding of consciousness. The patients are sleepy, drowsy, forgetful, dull and distracted. After these symptoms pass away, a marked impairment of memory might be noticed. In the more severe cases, complete unconsciousness may take place, which may persist only for a very short time, or for hours or even for days. On awakening, the patients remain thoughtless and clouded, show a marked disturbance of the perception sphere, especially in observing the finer points. Because of this, the patients are unable to obtain a clear conception of the impressions and events of their immediate surroundings; they may be aware of being in a hospital, but do not know its nature or have any idea of how they came there or why they should be there; they fail to recognize the people about them, and suffer from a confusion of identities. They do not notice the individual characteristics of the various people about them. Here and there a patient may develop disturbances of the sensorium, particularly visual hallucinations. Delusions of a depressive nature have also been seen in some cases. The patients have no insight into their condition and cannot understand why they are kept in the hospital, as there is nothing wrong with them. The perception disorders may simulate in many ways those of Korsakow's psychosis, in that the patients "confabulate" and suffer from marked retrospective falsifications of memory.

These patients have no recollection, or only a very faint one, of the accident, sometimes absolutely denying its occurrence, or they describe it differently at different times. The retrospective falsifications of memory which are observed mostly cover only a short period immediately preceding the accident. Here and there, however, these falsifications may cover a longer period, even years preceding the accident. These lapses of memory as a rule correct themselves almost completely, later on. This is perhaps due in part to the assistance of the information derived from friends. While the memory for remote events is, as a rule, retained, recent and immediate events are usually forgotten. The patient is unable to repeat short stories immediately after reading them, does not recall the names of those about him, does not know whether he ever saw them before, has no idea how he came to be in his present situation; in short, cannot recollect events of the most recent occurrence. At the same time, various falsifications of memory begin to make their appearance, either a mixture of truth and fiction, or wholly new fabrications.

These can be stirred up and influenced by persuasion. However, wholly fantastic and adventurous tales can be brought forth by these patients to which they hold very tenaciously. At times one can detect in these tales, which are usually described with the utmost minuteness, fragments of actual occurrences; others remind one of delirious or dream-state experiences.

Concerning time, these patients find themselves mostly in the dark. Above all, they are unable to give, themselves, clear account of the length of time which has elapsed since the occurrence of particular recent events; they do not know how long they have been in the hospital nor how long they have been under treatment, when they had visitors or when they saw the physician last. Heilbronner[4] showed that there exists a special tendency to set recent occurrences further back. Along with these, they are unable to orient themselves temporally, successively, for any length of time.

The mental activities of the patients are, as a rule, rendered considerably defective. They are distractible, can exercise their mental faculties only with the greatest difficulty, solve ordinary arithmetical problems very poorly, are unable to form a correct opinion of their condition or of occurrences in their environment. They apprehend badly, lose the trend of a conversation readily, and cannot apply themselves to any subject for any length of time. Later on, they develop a highly egotistic and very irritable disposition, are fault-finding, easily angered, and have outbursts of violent temper. Their affect tone fluctuates to a great extent; now they are elated, jolly and happy; now depressed and lacrimose. Disturbances of speech and writing also occur. They have difficulty in finding suitable words for expressing their ideas, have a tendency to form neologisms. Asymbolia and parapractic disturbances are also noticed.

The above kaleidoscopic description by Kraepelin is not, however, seen very frequently. Head injuries may be followed by no untoward, immediate symptoms. The patient may not even lose consciousness, but walk to his home and apparently not be the worse for the experience, until later—sometimes weeks and even months later—he begins to show a very noticeable change in his psychic total. His entire mental make-up changes, he becomes easily tired, is incapable of any prolonged mental effort, is forgetful, irritable and distractible. He complains of vertigo, pressure sensations in the head, migraine, noises in the ears; he experiences a sort of general benumbed feeling and shows a marked tendency to outbreaks of violent temper on the least provocation. He acquires great intolerance for alcoholic beverages; the slightest indulgence causes him to become intoxicated; he reacts in an extraordinarily severe manner to alcoholic stimuli. To this may be added epileptiform seizures, fainting attacks, and rarely, dream-states which may follow later.

Ziehen,[5] while in the main agreeing with Kraepelin, has gone a step further, in that he arbitrarily divides the traumatic psychoses into three forms: a primary and a secondary traumatic psychosis and a post-traumatic psychopathic constitution. The primary form follows immediately after the injury or after a short interim. This latent period may be as long as a week. If a prolonged coma follows the injury, the patient may emerge from same in a delirious state. The disease picture is characterized by numerous hallucinations, disorientation, incoherence, coordination disturbances, insane excitements and anxiety affects. At times it corresponds to the picture of a dream-state, then again, to that of an acute paranoia hallucinatoria. The gait simulates that of a drunken person and often feverish movements are present, even when no complication of meningitis or focal lesion exists. Intercurrent somnolence is not rare. Along with the marked association disturbances, severe memory defects are also found. These usually persist even after the acute symptoms pass over. The behavior of the patients is also changed and assumes a more or less characteristic coloring. They may develop catatonic states with severe impulsive outbreaks of violence and an aimless wandering back and forth. Recovery often follows and these acute disturbances may completely pass over. Other cases, however, may develop on top of these acute disturbances, a chronic psychic changed personality, thus merging into the secondary traumatic psychosis.

[5] Ziehen: Psychiatrie, second edition.

These belong in most instances to the defect psychoses and are characterized by gradual deterioration, the gradual development of a defective intelligence. We therefore speak also of a traumatic dementia, or feeblemindedness. Frequently this dementia may be mistaken for paresis, because of the physical disturbances which may accompany it. These patients may have various paralyses and incoordinations of movement and speech. Indeed, even on section, the brain may simulate closely that of paresis. In most instances this dementia remains stationary after reaching a certain point, and aside from a moderate weakness of judgment, a diminished capability for complex and especially for abstract conceptions, and a loss of the more intricate affect tones, the patients remain fairly normal.

In his last group Ziehen places cases of those who develop a so-called psychopathic constitution; that is, a well-defined distinct psychosis is wanting, but a careful comparison of the individual's mentality before and after the accident will reveal definite changes in his psyche. Those who knew the individual before the injury will invariably notice that he is more irritable, oppressed and very cyclothymic. He becomes easily tired mentally, evidences a loss of interest in things in general, lacks in quickness of judgment and foresight and shows a diminished capacity for mental productivity. He also acquires a marked loss of resistance to the effects of heat, emotions, tobacco and especially alcoholic beverages. Physically he is inclined to attacks of headache and dizziness, especially when bending over. There is also developed a suitable soil for the effects of other deleterious agents. An insignificant etiologic factor, which before the injury would have had no harmful effect on the patient, is of sufficient potentiality after the trauma to develop severe psychoses or psychoneuroses. The traumatic psychopathic constitutionality also carries in some instances the ear marks of neurasthenia and hysteria, very frequently also mixed hysteroneurasthenic states.

As will be seen from the preceding, the two authors differ chiefly in that Ziehen recognizes more forcibly the hallucinatory experiences, while Kraepelin lays much stress on the falsifications of memory. The general prognostic view held by these authors is quite an optimistic one, especially concerning the acute primary mental disturbances following head injury. As to the pathology of these cases, very little is known. In most instances there exist diffuse microscopic changes in the brain substance, characterized especially by minute hemorrhages and softenings. The location of the trauma plays no important part, and while as a general rule one would expect a quite severe impact in order to produce a general concussion and disturbance of the brain substance, mental disturbances have been known to follow quite trifling injuries to the head.

Audernach[6] reports a case of head injury in which the only external evidence of trauma was a small hematoma of the scalp over the occipital region. On examining the cerebrospinal fluid, blood was found, the patient later developing a psychosis. Here I think is an opportune moment to mention that in lumbar puncture we have one of the most certain guides in determining the extent of damage which the nervous system has sustained from a particular trauma.

The above authors have been quoted rather fully because their writings embrace the representative views of the German psychiatrists on the subject. I may add here that Kreuser,[7] after an exhaustive study of the subject, comes to the conclusion that it is very difficult to attribute to trauma the endogenous psychoses such as paranoia, mania, melancholia and hebephrenia.

CASE REPORTS

CASE 1.—A. B., white, male, aged 33, was admitted Nov. 3, 1904. Family history was negative; birth and childhood normal; school and occupational careers uneventful. He never suffered from any illness; uses alcoholic drinks moderately. July 27, 1902, he enlisted in the U. S. Navy and throughout his stay there was considered a good sailor. Oct. 5, 1904, at 11:30 p. m., while in a fight with another sailor, he was struck by the latter, fell down, striking his head on the pavement, was picked up by the police, who thought he was intoxicated, and taken to the first precinct station. There he was kept in the cell until 8 a. m. the next morning, when he was transferred to the casualty hospital. The naval authorities were communicated with and the patient was removed to the Naval Hospital on the same afternoon. The records of that hospital show that he was in a semi-comatose condition; pulse was slow and full; there was an odor of alcohol on his breath; there was slight confusion present, and a slight deviation of the left eye outward and upward. There were no paralyses and no vomiting; sensation was normal; temperature 100 F.; urine negative; involuntary urination and defecation; patient was restless. Behind the right ear there was a redness which appeared to indicate a fracture at the base of the skull, posterior fossa. Otherwise, no outward signs of injury to the skull were apparent. October 7, the patient appeared brighter; was taking nourishment; his brain was clearer; he answered questions; both pupils were equal and responded to light. There were no eye symptoms and no paralyses. Urination and defecation were involuntary; temperature between 98 and 100.4 F.; pulse slow and full. October 9, the patient's mind was clearer; he passed urine and feces voluntarily, and asked for nourishment; no localizing symptoms. October 10, mental condition not so good in the evening; involuntary evacuation of bowels and bladder; no localizing symptoms. October 12, the patient seemed stronger physically; polyuria was present; specific gravity of urine 10.06; acid; no sugar; no albumin; the patient had polydipsia. October 16, he talked irrationally; continually asked for water. October 18, he answered questions; could not tell his age correctly; talked disconnectedly. October 20, the patient was stronger; was restless; tried to drink urine; October 23, still wanted water; imagined he had $10,000,000 on the books; talked rapidly and at times disconnectedly.

The patient was admitted to the Government Hospital for the Insane Nov. 3, 1904, with a diagnosis of delusional insanity. On admission the physical examination was negative except for diminished patellar reflexes and absence of the plantar and cremasteric reflexes. Mentally he was dull, suspicious and apprehensive. Auditory hallucinations were prominent and he showed numerous delusions of a persecutory and grandiose type; complained of people cursing and abusing him; they were accusing him of performing certain indecent acts; heard someone say that they were going to spend $35 for poison with which to poison him. This same voice tells him that he is God and that he cannot die. Emotionally he was rather indifferent, seclusive on the ward, had no insight into his condition. As a rule, he behaved well but had frequent impulsive, violent outbreaks of anger, when he attacked other patients. He had no recollection of the accident, denied all knowledge of ever having been hurt or of having been arrested and subsequently taken to a hospital. All he knew was that he had a fever. In 1908 he was noted to still have pronounced auditory hallucinations and delusions of a persecutory type. Orientation, attention and comprehension were good; judgment impaired; no insight; at times the patient was depressed and worried; became easily excited and had a violent, uncontrollable temper, with frequent impulsive outbreaks of violence. At the time of writing this paper he is still confined to a ward for criminal insane on account of his violent, impulsive attacks on other patients. He is well oriented; has persecutory delusions, based on auditory hallucinations; no insight; is somewhat euphoric and egotistical; says that he is a highly educated man, and knows several languages. As a matter of fact, he speaks English very poorly and has great difficulty to find the proper word with which to express himself in his native tongue.

[7] Kreuser: Württemb. Ztschr. f. Rechtspfl. u. Verw., ii, No. 1.

On closer questioning a retrospective amnesia, extending for a period of about two days before the accident occurred, was found to exist. He still denies all knowledge of the accident. There can be no doubt that this man's psychosis followed on the heels of the head injury, and his mental disturbance corresponds to a typical paranoid state. The patient shows now, over six years after the accident, no perceptible deterioration.

Case 2.—F. L., aged 58 on admission June 16, 1910. Nothing is known of his family history; birth and childhood normal; school and occupational careers uneventful. May 25 or 26, 1904, while in Alaska, he was struck over the head with a club during an altercation with three other men, two of whom he shot and killed, for which he is now under sentence for twenty years. The prison authorities state, in the papers which accompanied him on his transfer here, that he was erratic since admission to the prison Oct. 19, 1906. December 14, 1909, he was placed in an isolation ward for observation on account of writing scandalous letters and throwing them on the gallery of the cell-house, in order that other prisoners might pick them up and cause trouble. He has delusions of persecution. Diagnosis, paranoia.

Physically, on admission here, he showed a slight, coarse tremor of extended fingers; pupils were irregular in outline; mentally he was nervous and irritable; was as a rule cheerful and self-satisfied; quite talkative, and his conversation showed a marked degree of circumstantiality. He had a very exaggerated ego and was at times quite witty and quick to catch a joke. He comprehended well and his replies were coherent and relevant as a rule, but at times he would bring in a lot of irrelevant matter. His attention was mobile; consciousness unclouded; no delusions or hallucinations could be elicited; memory apparently unimpaired; emotionally he was cheerful as a rule, but inclined to be very cyclothymic; at times very irritable and fault-finding; made numerous requests daily; was always busy doing something on the ward.

He had numerous suggestions for the improvement of the hospital; read a good deal, and whenever seen, he commenced to elucidate a new scientific subject which he had been studying. He was neat and tidy in his habits but somewhat careless; was friendly towards those about him. He stated that ever since the injury his head had been "on the bum." For a long time after the injury he had frequent attacks of swooning, and on stooping over or turning in bed he often felt as though he would slide or pitch over. He asked to be sent here from prison in order to have his brain examined with an *x*-ray machine, and if it showed up any rotten spots like a specked apple, his skull could be opened and these spots scooped out. At the time of writing this paper the patient is in a state of mild hypomania; he is constantly busy with something or somebody on the ward; has numerous ideas as to improvements which should be instituted in the hospital; continually jumps from one subject to another without any directing goal. He possesses a pathologic degree of euphoria, is very unstable emotionally, somewhat irritable and impatient in a conversation, always wanting to have the upper hand; writes voluminous letters, using very flowery descriptions, and underscoring them in numerous places. He shows no clouding of consciousness and no appreciable memory defect, except that he is not certain about the date of the accident; he thinks it is either the twenty-fifth or the twenty-sixth of May. Here is a part of a conversation held with him Nov. 1, 1910:

"How do you feel, Mr. L.?" "I feel—say, I had a fine walk to-day; say, you see those gutters out there? They are natural sluices; we of course make them out of boards; so they started to inquire about me up there at the post-office. Say, I wish you could read that letter I wrote to the Attorney General." "You haven't told me, yet, how you feel, Mr. L." "All right, but say I had a swoon and my head goes round. Tell me what is epilepsy? I would like to know; you know they beat me unconscious; that letter, though, explains the whole thing; even the others said so," etc., etc.

The symptom-complex in this case resembles very much a typical state of hypomania, and there is very little doubt that its inception dates back to the time of the injury. The prison officials noted him to be erratic on arrival at the prison. His transfer to this institution probably became necessary because of an aggravation of his condition; this may perhaps be due to some arteriosclerotic changes in the brain. The patient is in the arteriosclerotic period.

Case 3.—N. M., a white man, aged 57 on admission June 18, 1910. One brother died of paresis, a sister at the time of his admission suffered from the fourth attack of recurrent mania; patient was always a man of limited mental endowment: he was the oldest boy in his class and was graded the lowest, reaching the third grade at the age of 12. He led an uneventful life, always using alcoholics. May 14, 1910, he was thrown to the ground from the rear platform of a car, sustaining a fracture at the base of the skull, on which a decompression operation was performed May 20. Following the accident the patient was in an almost completely unconscious state until the time of the operation six days later. He states that all he remembers was that he had a pain in his head. Following the operation he was confused, excited and at times violent; was very restless, wandered away from the house, losing his way, and was picked up on the street by the police and taken to the station house. On admission here, about a month after the injury, the patient was still slightly confused, but he cleared up in a very few days and was discharged recovered three weeks after admission. This case is a fair illustration of a simple confusion or delirious state following head trauma, with a complete recovery.

Case 4.—B. McK., a white man, aged 28 on admission Feb. 19, 1908, from the Naval Hospital at Philadelphia. The patient was a primitive individual of very meager attainments; early childhood and youth uneventful; at the age of 14 he fell, striking his forehead, and sustained a scalp wound which bled very profusely. His occupational career following this was of the lowest type; he would do any common labor which he could get, and finally on May 9, 1906, he enlisted in the U. S. Navy. In March, 1907, while on the ship *Connecticut* he fell from his hammock striking his head on an ammunition pack. Following this, he developed severe headaches, loss of memory, was frequently absent from duty for a day or so without any apparent cause, and could give no explanation for such absences; he had violent outbursts of temper, was very suspicious, seclusive and melancholy. Physically he showed a fibrillary tremor of extended fingers, knee-jerks slightly exaggerated, mild ankle-clonus, especially on the left side, speech somewhat thick and ataxic. After a short stay in the hospital he cleared up completely and was discharged July 2, 1908, as recovered. This is another illustration of mild mental disturbance, resembling somewhat a confused or delirious experience, following head injury, and which cleared up after a short time.

Case 5.—R. P., white, male, aged 44, Scotchman; family history negative, birth and childhood normal. He attended school between the ages of 4 and 17, graduating from grammar-school at 15; states that he was one of the first in his class. He launched on his occupational career immediately after leaving school, entering a jute concern as an apprentice and remaining there for three years. There he learned bookkeeping and business methods, and the inspection of jute. He made good progress and left at the expiration of his apprenticeship. While there he attended night school for six months. On arriving in this country at the age of 17, he soon obtained a position with a New York dry-goods firm, leaving that firm after a sojourn of one year because he had obtained a position as bookkeeper at a better salary. Here he remained four years, when he left and went on a three months' visit to Scotland. On returning to this country, he received a position as hier for a metal company. This position he held for two .rs, when he was appointed manager of a real estate concern a better salary. He used alcoholics in moderation up to)6, but was never intoxicated to his knowledge up to that ne. In 1896 (the patient does not remember the exact date), the age of 33, he was thrown from a horse, striking his ad on the pavement. He denies having been intoxicated at : time of the accident. He was picked up in a dazed condin; does not think he was totally unconscious at the time; nembers trying to get up but was unable to do so. He was ken to his boarding-house but has no recollection of this, members faintly being put to bed and having a severe conlsion; thinks the convulsion started with the muscles of the 't side of his face and neck; remembers that his tongue was ing protected by a spoon placed in his mouth; also that s fingers were in a spasm; lower extremities were not volved and he was not unconscious during the attack. He as told afterward that in one day he had thirty-six seizures. hese epileptiform attacks lasted for a period of two weeks. e believes that he struck on the vertex of the skull over the rietal region; also suffered from occasional headache at that me. Vision and audition are unimpaired; there was no eeding from any of the cranial apertures. Immediately folwing the accident he lost the power of speech and it was lly two months before he could articulate. According to is description of the speech defect, it was in all probability purely motor aphasia. He says the words would come to is mind but he could not express them. After a stay of two eeks at his boarding-house, he was removed to a hospital here he remained four months; he says that his memory was ffected during this time; that he was unable to think norally, and is certain that he was confused for some time ollowing the injury. He states that he had no clear recollecion of the accident, and that it was his friends who supplied im with the details. A letter which he wrote home about wo months after the accident was kept by his people as evience of his abnormal mental state. He recollects that he was ble to perform the mechanical part of the writing, but that is ideas were confused. He gradually improved and was nally discharged as recovered. After leaving the hospital e obtained a position with a bicycle firm where he remained or two years; when the Spanish-American War broke out, e volunteered, and after eleven months' service in Georgia, e obtained an excellent discharge. He then joined the regular rmy and after serving his enlistment in the tropics was sent ome with an excellent discharge. During this term of servce he was summarily court-martialed four or five times, mostly for absences without leave, caused by his alcoholic indulgences. On being discharged from the army, he obtained a position as night clerk in a hotel, where he remained until 1906, when he reenlisted and was assigned to recruiting duty at San Francisco. At this he remained for about two months, during which period he had a summary court-martial for absence without leave, caused by drinking.

Shortly afterward, complaining of sore throat, he was sent to the observation ward of the general hospital at the Presidio and later was transferred here. The medical certificate on his admission stated that the patient used alcohol to excess; that on admission to the Presidio Hospital, he was nervous, egotistical, pugnacious, prevaricated, had fixed delusions about religious matters, was obscene, abusive and irresponsible. Physical examination was negative except for dilated facial capillaries and tremor of the extended fingers.

On admission here he showed a hypomanic state, was excited, had flight of ideas and prevaricated much. Later on, a depression set in, from which the patient gradually recovered. "Confabulations" were marked throughout. He was discharged Nov. 23, 1910, to accept a position with the Salvation Army, after a sojourn in this institution of almost twenty-eight months.

The life-history of this patient has been gone into with more detail in order to show how his head injury marked the turning point in his career. A Scotchman of average education, he came to this country and launched on a career which showed a steady ascent, at the age of 33 having reached a well-paying position as manager of a real estate firm. He meets with this head trauma, and we next see him occupying a low-salaried position in a bicycle shop. Then he turns to the army. Here he apparently finds great difficulty in adjusting himself to the prescribed, well-regulated army life. He was court-martialed five times during his first enlistment. He makes another attempt at getting along on the outside, but fails and finally returns to the army. The second attempt here starts out with a court-martial, and he finally breaks down, developing a psychosis. After spending twenty-eight months under the well-regulated and tranquil life of an institution, he lands in the Salvation Army, one of the havens for human derelicts.

Here, indeed, the far-reaching effects of a head injury can well be seen. In his case, it robbed him of the forces which are so essential for the battles of life, the faculties which bring about an adjustment between individual and environment. The importance of this class of mental disturbance to the general practitioner, and especially for the practicing neurologist, can hardly be overestimated, especially when we remember that according to Friedman's statistics, 60 per cent. of all concussions of the brain are followed by psychic disturbances for a year or more after the injury, and that according to Ziehen, the traumatic psychoses form 3 per cent. of all admission to hospitals for the insane. The general practitioner is the first one called on to attend these cases, and while he is prepared to meet the immediate effects of the head injury, he must not forget that next to the question of whether the patient is going to live or not, he is confronted with the problem of giving a prognosis as to what effects the injury will have on the patient's future life.

It is conceded by many that injuries of the brain, if not severe enough to prove fatal, heal very benignly; and the question of paramount importance which then comes up is not one of immediate interest, not one of death and life, but one of a more far-reaching importance, namely, "How will the future life of the patient be modified by this injury?" It must also be borne in mind that liability litigations, and suits for damages often arise in these cases, and the physician is the one called on to give the most important evidence in the case, namely, to what extent the individual has been deprived, by this injury, of his physical and mental earning capacity.

I have refrained from discussing the various neuroses or psychoneuroses which may follow trauma of any kind, and head trauma in particular, because my cases deal exclusively with the psychic part of the question. I will, however, mention in passing, that a score of German neurologists, headed by Mendel, now recognize a definite liability-law-hysteria of neurosis; that is, the existing liability law forms the psychogenic factor in these cases. I mention this because the question of malingering, simulation and exaggeration of symptoms, may also occur in what appears to be the purest kind of traumatic psychosis. Kreuser, however, comes to the conclusion that the above traits are rarely concomitants of the symptom-complex following head injuries. The common picture is one of such a severe disturbance of the individual's affects as to lead the victim to the life of a tramp and criminal.

CONCLUSIONS

The above considerations lead me to the following conclusions:

1. There is no psychotic entity which can be diagnosed as a traumatic psychosis without a history of a

definite relation of the mental disturbances to a preceding trauma of the head.

2. Contrary to Kreuser's views, even what he terms endogenous psychoses can be brought on by head injuries, as our paranoid and hypomanic cases show.

3. The prognosis is favorable in the cases which show acute mental disturbances, such as acute delirious or confusional states, while in those cases which resemble what Kreuser terms the endogenous psychosis, the prognosis is extremely bad. The hypomanic patient is still insane six years after the injury, while the paranoid patient has shown no appreciable improvement since the occurrence of the accident in 1904.

4. The last one of my series of cases shows that head injuries may have a lasting deleterious effect on the individual; that while a cross-section at any particular point may not show any gross pathologic findings, yet a study of the entire individual's life will reveal a decay of his finer functions of intellect, which stamps him as a chronic psychic invalid.

THE PROGNOSIS AND END-RESULTS OF TREATMENT OF GASTRIC ULCER

GEORGE R. LOCKWOOD, M.D.
NEW YORK

The prognosis of gastric and of duodenal ulcer, as regards the percentage both of the mortality and of the curative effect of treatment, is difficult to determine. A mass of statistics is available but in many respects these statistics are insufficient and misleading. This applies to the reports of both medical and surgical cases.

Many of the discrepancies that exist between the statistics of physicians and surgeons are due to the fact that they refer to entirely different types of ulcer. The physician meets varieties that are not apt to come at any time under surgical observation. The physician sees all kinds; the surgeon sees only a limited number and a limited variety.

Let us consider for a moment the varieties of ulcer that come under the care of the physician and compare these with the varieties of ulcer that come under the care of the surgeon.

I. The physician is called on to treat as ulcer, three distinctly different sets of cases:

First, there are acute ulcers, constituting 15 to 20 per cent. of the total number of ulcerations. These are almost regularly amenable to medical treatment and afford a large percentage of the cases of ulcer in which permanent cure is obtained. It may be said that permanent cure is obtained in at least 90 per cent. These acute ulcers, however, by reason of their tendency to hemorrhage and perforation, add materially to the mortality rate. They do not come as a rule under the observation of the surgeon, except in the event of perforation, or more rarely of hemorrhage.

Second, there are cases of chronic ulcer with or without complications, such as recurring hemorrhages, perigastric adhesions and pyloric stenosis. These are the purely border-line cases and are seen alike by the physician and surgeon. The prognosis in these cases depends, (1) on the actual number that are really cases of ulcer; (2) on the thoroughness of the medical treatment, and (3) on the care that the patient takes of himself during his convalescence. These are practically the only ulcers which the surgeon sees and he sees only a part of them.

Third, there are the cases which are diagnosed as ulcer but which are not ulcer. When a surgeon operates on a patient, he sees the ulcer and recognizes it as such. The physician, on the other hand, makes his diagnosis without the benefit of such palpable and visible evidence, and may or may not be correct in his conclusions. It is certain that very many patients are treated for ulcers who are really suffering from chronic appendicitis or gall-bladder disease.

A few years ago, wishing to trace the end-result of ulcers treated by me, I sent circular letters of inquiry to former patients, limiting the inquiries to those alone in whom the diagnosis of ulcer seemed certain.

Twelve per cent. of the replies received were to the effect that after the ulcer treatment, the symptoms had improved but had not entirely ceased, until, after an acute attack of appendicitis, the removal of the appendix had been followed by entire and permanent cessation of the gastric symptoms. This experience has never been forgotten.

In a recent article Cabot gives the results of a series of autopsies at the Massachusetts General Hospital, and finds that peptic ulcer, gastric and duodenal, was correctly diagnosed in but 36 per cent. of cases; ulcer was present, but not diagnosed, in 56 per cent.; ulcer diagnosed, but not found, in 8 per cent.

In my experience, from 12 to 18 per cent. of cases treated as ulcer are treated on a wrong diagnosis. Here comes in the weakness of the medical statistics. No only are we liable to commit diagnostic sins of omission and of commission, but the range of such errors varies according to the different observers. One physician wil not make a diagnosis of ulcer unless confronted by a case that runs a classical course, or one attended by hemorrhage or perforation, while another with equa clinical experience will diagnose ulcer on far less posi tive evidence.

It is evident that if one waits for an ulcer to run an aggressive and unmistakable course before making a diagnosis, one's mortality rate will be higher than i one included the milder and more amenable cases. Th personal equation has a most important influence on statistics.

If, on the other hand, ulcer is too readily diagnosed we shall include a large number of cases of chroni appendicitis and gall-bladder disease, and thus be led t incorrect conclusions.

The inclusion of these cases incorrectly diagnosed will not add to the percentage of mortality, but rathe to the reduction of the death-rate. On the other hand it is obvious that we materially increase the percentage of those who are merely improved, or unimproved, and we reduce the number of those clinically or permanently cured.

II. The surgeon, on the other hand, sees very few o the acute cases except in the event of perforation o hemorrhage; nor does he include among his cases o ulcer, those in which the ailment has been incorrectly diagnosed. He sees only these chronic ulcers with o without complication, in which exploration proves th diagnosis to be correct. Nor does he see all of these cases. He merely sees such a proportion of them as have proved rebellious to medical treatment, either because the ulcer was not one that could be cured by medicine and diet, or because the treatment by the physician had been insufficient, or because the patient had not been intelligent or persevering enough to carry out the treat ment for a sufficient length of time.

It is natural for him, therefore, to take a more gloomy view of the results of medical treatment than would seem warranted by facts. This brings us to the difference in prognosis according to whether the statistics are compiled from private or from hospital sources.

In hospital cases the mortality is naturally greater than in private practice, because of the greater severity of the cases admitted and because of the larger proportion of cases entering the wards with severe hemorrhage or perforation. In 100 consecutive Bellevue Hospital cases, 17 per cent. of patients were admitted because of alarming hemorrhage; 7 per cent. because of perforation.

The results of treatment are very different in the two classes. For medical treatment to produce results in chronic ulcer, it should be continued for a long period of time, even after the cessation of symptoms. Hospital patients remain in the wards just as long as they suffer pain, and leave as soon as they are fairly comfortable, returning to a promiscuous, unsuitable diet and to a disregard of all medical conventions. No wonder, therefore, that so many are unimproved and that so many relapses occur. It is only after alarming hemorrhage that many of the hospital patients will undergo any treatment at all. The comparatively small number of perforations which occur in patients who have had an ulcer treatment because of hemorrhage shows the beneficial effect of medical treatment, even though it be inadequate to effect a permanent cure.

The difference between hospital and private cases has been well shown by Musser in a recent article. According to this writer, the mortality from ulcer treated medically in private practice was 3.1 per cent. In patients treated medically for ulcer in hospitals, the mortality was 12.4 per cent. These are figures compiled from a large number of sources.

Musser concludes that about 8 per cent. of ulcer patients, combined private and hospital, die as the result of the disease.

My own experience coincides remarkably with the figures just given. The mortality of ulcer treated in private practice has amounted to 3.1 per cent., the precise figure given by Musser. If we exclude the patients who are practically moribund when first seen, however, the mortality after treatment was begun was almost negligible. In compiling these reports of hospital cases, however, I have excluded those in which death resulted from intercurrent disease, not associated in any way with the gastric ulceration, comprising three cases of acute lobar pneumonia, one of uremia, one of arteriosclerosis and cerebral hemorrhage, in which chronic ulcer in the stomach was found at the autopsy, which had given no symptoms during life and which had in no way contributed to the death of the patient.

The general mortality of private and hospital patients combined, amounted to a little less than 7 per cent. My figures include about 175 ulcers in private practice, eighty-four in hospital.

PROGNOSIS OF ULCER TREATED SURGICALLY

Operation for gastric ulcer yields far better results when done by experienced operators than when done by the profession at large. The results obtained by such men as the Mayos, Robson, Moynihan and Finney, afford striking proof of their clinical wisdom, their skill in operation and their infinite genius for painstaking work.

In the leading hospitals of this city, gastro-enterostomy is done with a mortality that probably does not exceed 2 per cent. The result has been that gastro-enterostomy is no longer regarded as a formidable operation. One prominent New York surgeon writing to me on this subject says: "The operation in a benign condition is but a little more dangerous than an interval appendix operation."

It would be very unfortunate indeed if the general impression prevailed that gastro-enterostomies could be done as safely as this. These men are specialized surgeons and skilfully trained. The mortality of the operation as done by the profession at large is quite different, and the reports of physicians whose patients are operated on by different surgeons of more or less experience are not so very satisfactory.

In 150 benign cases quoted recently by Bettman and White, the immediate mortality was 10 per cent. Musser's combined statistics show fatalities in 11.4 per cent. of cases in private practice, 20 per cent. in hospital. Hall reports six deaths of his patients operated on by different surgeons. Dunham within two weeks reports that of forty-eight patients with ulcer under his care, on whom operations were performed, twelve died within seventeen days and six of these within three days, making an immediate mortality of 12.5 per cent. He estimates the mortality of operation for gastric ulcer in the past four years to be a trifle over 10 per cent.

Before accepting this figure of 10 per cent. mortality by surgical treatment, two facts must be considered:

1. It is but fair to the surgeon to say that many physicians are often extremely remiss in dallying too long with medical treatment, and turning over to the surgeon as a last resort an exhausted, starved and often bloodless patient. It is but fair to the physician, on the other hand, to say that the recent improvement in surgical statistics is not alone due to improvement in the surgical technic, but in great part to the wisdom of the physician in calling in surgical help earlier and in better-selected cases.

2. The ordinary operation for gastric ulcer is gastro-enterostomy and the low mortality rate of gastro-enterostomy is fixed in a few medical, and in many surgical minds, as the general surgical treatment of ulcer. As a matter of fact many ulcers are excised, some in accessible regions, others in regions more difficult to approach and these more severe operations raise the death-rate materially over that of gastro-enterostomy pure and simple.

It is very likely that many of these complicated operations are included in statistics under the general heading of gastro-enterostomy. In this way we may be unfair to gastro-enterostomy as an operative procedure, but, on the other hand, the operative results thus obtained are the real surgical risks of operative treatment of ulcer.

My own figures are as follows:

Twenty-six private patients operated on for ulcer in the past six or seven years, with six deaths, two after exsection and gastro-enterostomy; four after gastro-enterostomy alone. I believe that all but one (on whom exsection was performed) were good surgical risks and were carefully selected cases. No patient on this list had hemorrhages or perforation. No death was due to faulty technic as far as I can see. There were two vicious circles requiring secondary operation, and one jejunal ulcer that required four ulcer treatments for its cure.

I would conclude, therefore, as to mortality percentages as follows: (1) mortality in uncomplicated gastro-enterostomy by a skilled surgeon, 2 to 3 per cent.; (2) by the average surgeon, 6 to 8 per cent.; (3) general operative mortality including exsections, not far from 10 to 15 per cent., when performed by good men.

It is extremely important for the physician in charge of an ulcer case, that requires surgical interference, to choose as his confrère an operator of known skill and experience in gastric surgery whose death-rate is increasingly low.

END-RESULTS OF MEDICAL TREATMENT

It is difficult to arrive at satisfactory conclusions by a study of the statistics available, because, as a rule, the patients are not followed long enough to determine whether or not the ulcer has actually healed. The relief, or even the total cessation, of symptoms should not bring an erroneous belief that the ulcer is healed, for in many of the patients, even in those who conscientiously carry out the instructions of their physician, symptoms of ulcer sooner or later reappear, and the relapse may be as serious as was the original attack.

The length of time of freedom from symptoms which must elapse after treatment before the patient can be declared cured is an arbitrary one, but it may be said that two years at least must elapse without symptoms before any conclusions can be drawn.

It is obviously more difficult to trace hospital patients than those seen in private practice, but when they can be followed, it will be found that relapses are much more frequent than in those whose mode of life and intelligence guard them from the obvious faults of living which militate against those in the lower walks of life. The longer the patients are followed, the greater is the number of medical failures that become evident. No value can be attached to the reports of cases that are not followed for at least two years. It may be said from a study of statistics that conform to scientific requirements, that, under medical treatment, about 80 per cent. of patients are apparently cured, and that in hospital practice one-half of these, and in private practice one-quarter of these, relapse, making a permanent cure in 40 to 45 per cent. of hospital cases and 60 to 65 per cent. of private cases.

Greenough and Joslin found that in the Massachusetts General Hospital, while 82 per cent. of patients with ulcer were discharged as "cured" or "relieved," only 40 per cent. remained well. Sears estimates the number of medical failures after five years at 50 per cent. Mumford and Howe estimate 80 per cent. of apparent cures, of which one-half relapse. Hewes, in fifty-one cases, found forty-eight patients apparently cured; in two years 63 per cent. of these remained well. Paterson, in seventy-two hospital patients discharged as cured, found that but nineteen remained well, seven were doubtful, forty were still suffering, five had undergone surgical treatment, and one had died.

In the remaining 20 per cent., the immediate result is not brilliant, a certain amount of distress still remaining, although as a rule the patients are benefited to a greater or less extent by their treatment. The number of those who show no improvement whatever is relatively small, probably not over 5 or 6 per cent. It is quite certain that many of these improved or unimproved cases are not ulcers at all.

In 1897 Von Leube, in a communication before the Thirteenth Surgical Congress, announced that, whereas the former mortality of ulcer had been as high as 13 per cent., the enforcement of the rigid treatment inaugurated by him had been promptly followed by a marked reduction in the death-rate. In 556 cases reported by him, 74.1 per cent. of the patients could be considered cured, 21.9 per cent. improved, 1.6 per cent. unimproved, and 2.4 per cent. had died.

In 1909 Von Leube[1] gave the total of his later results to date and they show a surprising improvement over previous records.

Of 627 patients treated in the previous eleven years in his clinic and in his private practice for ulcer, with and without hemorrhage, 566, or 90 per cent. were clinically cured, (76 per cent. within four weeks, 14 per cent. in a period longer than this); fifty-three, or 8.5 per cent., were improved; six, or 1 per cent., remained unimproved, and two patients, or 0.3 per cent., died as the result of hemorrhage.

Tabulating the ulcers that were attended by hemorrhage, he found that seventy-two patients, or 90 per cent., were clinically cured (66 per cent. within five weeks, 24 per cent. in a longer period of time than this). Five, or 6.25 per cent., improved, one, or 1.25 per cent., remained unimproved, while two patients, or 2.5 per cent., died.

These are astounding results. I make use of the term "clinically cured," however, because Von Leube states in his communication that he regards as "cured" those patients in whom the symptoms disappear for a period of three weeks, and in which ordinary hospital diet, not especially prescribed for gastric cases, but given to those patients whose digestion is good, is eaten without discomfort. He notes that occasionally an ulcer is only apparently cured, and, that after a longer or shorter time, pain, dyspepsia and hemorrhage may reappear; but in his experience such a relapse occurs only in very rare exceptions.

It is unfortunate that Von Leube has not followed up his cases for two years or more, and given us the end-results thus obtained, because as they stand at the present time they give us only the temporary result of treatment; further than this they mean nothing. My experience leads me to believe that under a rigid ulcer cure fully 90 per cent. of patients may be considered "cured" in the sense in which that term is used by Von Leube, but I am not so optimistic as to the after-results of treatment.

Of the patients I treated for ulcer by a rigid and thorough ulcer cure, and followed for over three years, 66.6 per cent. were clinically cured, 16.6 per cent. relapsed, leaving 50 per cent. permanently cured; 22.2 per cent. were improved, 5.5 per cent. were unimproved; 5.7 per cent. of the patients died (not, however, as the result of ulcer).

END-RESULTS OF SURGICAL TREATMENT

Owing to the fact that the great advances made in gastric surgery have been so recent, notwithstanding the large number of patients operated on, only a few can give a postoperative history of sufficiently long duration to be authoritative as to ultimate results. It must be conceded, however, that in no other field of operative work have more brilliant results been effected, both as regards degree of improvement and permanency of cure. Since the reports were written, however, under the excitement of their successes, it is possible that too much has been claimed by operators for surgery.

Deaver writes: "Surgery allows 95 to 98 per cent. of patients to recover." At the same time he published the table reproduced here of surgical end-results, in which the average of cure is but 86 per cent.

END-RESULTS OF OPERATIONS FOR BENIGN DISEASES OF THE STOMACH AS SHOWN BY DEAVER

Operator	Patients Traced	Cured	Percentage
Mayo (1908)	234	189	80.7
Moynihan (1908)	247	211	85.42
Czerny (1902)	53	44	83.0
Robson	96	89	92.7
Deaver (1900-1907)	64	49	76.5
Deaver (1905-1907)	31	26	83.87
Paterson (collective statistics)	116	109	93.9
Helferich (1905)	56	41	73.3

In Deaver's[2] own patients who were traced, only 58 per cent. had no gastric symptoms after operation, 14 per cent. were markedly improved, 6 per cent. were unimproved, while 14 per cent. had died, either from the original gastric lesion (two probably from cancer) or from some late complication such as intestinal obstruction, or vicious circle indirectly caused by the stomach condition. If we include in the surgical statistics the results of operative treatment administered by surgeons of less experience and skill, the showing is certainly not so much in favor of surgical intervention as we have been led to suppose.

Bettmann and White found that of 126 patients who survived the operation (10 per cent. having died as an immediate result of the operation), and who were under observation for a year or more, only 64.3 per cent. remained well, 6.3 per cent. were much better, while 24.7 per cent. reported as little or not better.

Paterson, by tracing the history of 116 patients who had been operated on by gastro-enterostomy at periods varying from two to nineteen years, concludes that but 85 per cent. are permanently cured. I believe that the latter figure, or even a little less, will be nearer correct than the high estimates given; that 2 to 10 per cent. will die directly or indirectly from the operation, depending on the individual surgeon who operates, and that probably 15 per cent. will derive but little benefit from their treatment.

The surgeon is too apt to regard the patient with ulcer as cured as soon as the operation is over. Properly speaking, the cure has only just begun. Every patient operated on should have an after-cure more or less strict. The proper healing of the ulcer, the cure of multiple ulcers, the danger of fresh ulcers and a lessened risk of jejunal peptic ulcers, are the reasons why such an after-cure is imperative.

I would be more inclined to employ surgery as a routine were I more fully convinced that malignant degeneration of ulcer occurs as often as it is said to do by certain operators and pathologists.

It has been known for sixty years that in a certain number of ulcers, malignant changes occur, the older writers placing this frequency at 6 to 8 per cent. basing their conclusions on the result of post-mortem examinations. In the advanced cases of malignancy that come to autopsy it is often impossible to decide whether signs of previous ulceration are present, and it is therefore to the surgeon. who has the opportunity of examining the early stages of malignancy, that we must look for accurate data on this subject.

The statements are now made that about 70 per cent. of cancers of the stomach originate from ulcer. If this be so, it must give us pause and compel us to turn to surgery as a preventive of this dread disease in our chronic ulcers.

This pathologic statement as to pathology, however, is at variance with clinical observation. Were 70 per cent. of cancers preceded by a stage of chronic ulceration, a previous history of ulcer would be found in the great majority of the cases. Here physicians and surgeons divide.

In 150 cases of cancer, Osler found an ulcer history in 2.6 per cent, and in not a single instance could it be positively diagnosed. Fenwick obtained an ulcer history in but 3 per cent. of his cancer cases, Haberlin in 2.3 per cent., Eichhorst in but 2 per cent.

In 174 cases of cancer in my care in which the history is complete, 147 patients gave absolutely no previous history of any indigestion whatever; fourteen gave a history either of alcoholic excesses and morning vomiting, or of indefinite dyspepsia that was practically negligible; while only thirteen gave a history that might point toward gastric ulcer; so that in but 7 per cent. could such a surmise be entertained. A positive history of ulcer was obtained in but 3 per cent. of cases.

This immunity from previous history of indigestion in cancer was evidently the older surgical idea.

Robson in 1901 writes in his book on cancer: "It is, however, rare to elicit a history of very old-standing stomach disorder; the first evidences of local disease appear suddenly in persons of perfectly sound health and robust digestion." In 1907, six years later he writes: "In no less than 59.3 per cent. of cancer of the stomach on which I have performed gastro-enterostomy for the relief of symptoms, the disease having advanced too far for gastrectomy, the long history of painful dyspepsia suggests the possibility of ulcer preceding the onset of malignant disease." This is a pretty rapid and radical change of ideas!

If ulcer preexists in 70 per cent. of our cancer cases, how is it that we can obtain a clinical history of ulcer in but 3 to 4 per cent. of these cases? Is it that we do not know an ulcer history when we see one, or recognize one ulcer history to the surgeon's fifteen, or is the surgical estimate based on wrong premises and unsupported by clinical experience?

Furthermore, we all have watched patients with ulcer, many of them for years. How many become cancerous after months or years? In my experience the late development of cancer on an old previous ulcer is exceedingly rare. I cannot say that the statement that 70 per cent. of cancers arise from ulcer is wrong, but regard it as important to consider and to verify. I do not regard it as proved at the present time.

INDICATIONS FOR SURGICAL TREATMENT

During the past few years, the relative indications for medical and surgical treatment of ulcer have been fully and freely discussed, with the result that at the present time physicians and surgeons have come to think and act in perfect harmony with each other. There is no such thing as an exclusive medical treatment, nor can it be affirmed that ulcer is purely a surgical disease; but while some ulcers are to be treated medically, and others call imperatively for surgical treatment, the majority are grouped near the borderline.

Acute, uncomplicated ulcers are best treated medically. This is conceded by all surgeons, who often designate this form as "medical ulcer." Relief by medical treatment is usually prompt and lasting.

Chronic, uncomplicated ulcer should not be regarded as surgical until, after a rigid and systematic course of treatment, the symptoms persist or recur. The main indication for surgery is in the failure of medical treatment to give beneficial or lasting results. It must be emphasized that the treatment should be thorough, and continued for a sufficient length of time, as medical failures are more often due to half-hearted and insufficient treatment than to actual limitations of the medical art. No treatment can be considered efficient that does not include rest in bed for at least three weeks. In general terms, it may be said that ulcers which do not yield to two months' active treatment will probably prove resistant to surgical procedures. Some consideration must, however, be paid to outside conditions, such as the amount of time that can be given to treatment, or the probability of the patient taking sufficient care of himself during the convalescent period, to prevent relapse or recrudescence. In the case of a laboring man whose family is dependent on his daily wage for the necessities of existence, and who is apt, on leaving the hospital, to disregard all dietetic rules and conventions, it may be better to recommend surgical intervention earlier than would be advisable in the case of those whose intelligence and environment allow of a conscientious observance of the details of treatment.

---

[2] Deaver and Ashhurst: Surgery of the Upper Abdomen, i, 108.

If, after a vigorous medical treatment, the symptoms persist, or, if in spite of every precaution, there should be relapses, indicating that the healing of the ulcer has not been complete, surgical treatment is indicated. The mortality rate and the percentage of cures are both on the side of surgery in these cases.

Exploration is demanded without loss of time in all cases in which there is a suspicion of malignancy.

Single large hemorrhages are best treated medically. If the bleeding is stopped by medical means, no harm is done, while the operation of opening the stomach and ligating the bleeding point, when the perforation occurs during a period of acute anemia, is extremely hazardous. Hemoglobin tests under 35 per cent. contra-indicate operation except in emergencies, in which great risks may be taken. On the other hand, hematemesis that ceases spontaneously is often accompanied by anemia even greater than this.

Recurring hemorrhages, if not relieved by a course of medical treatment, may properly be placed on the surgical list, especially if the continued loss of blood occasion a progressive anemia. In these cases operation should not be too long deferred, as there may be complicating malignancy present. Cases in which occult bleeding follows every attempt to place the patient on solid food, after a regular ulcer treatment, should invite surgical intervention.

Perforation, either acute, subacute or chronic, is a purely surgical complication. Acute perforations demand instant operation, as every hour which elapses until the aperture is closed diminishes the patient's chance of recovery. Immediate laparotomy is called for alike in those cases in which there is a slight amount of initial shock, such as are often encountered with duodenal perforations, and in those patients in whom initial shock is profound. It would be a fatal error in judgment to temporize in the one case until the indications for interference become more manifest, or to defer laparotomy on the other, in the hope of bringing the patient into a better physical condition to withstand an operation.

Pyloric obstruction, hour-glass contractions of the stomach or *persistent adhesions,* which interfere with the proper drainage of the stomach into the bowel, are to be treated surgically, although in the majority of instances, preliminary treatment by lavage and diet may so improve the general condition that the operation is performed with a minimum of risk.

Adhesions, whose presence is only to be surmised, and which do not interfere with the proper motility of the stomach, are best left untreated. An exception may be made in those perigastric adhesions, especially those between the lesser curvature of the stomach and the under surface of the liver, which are dragged on by physical exertions, or even during locomotion, and which give rise to such discomfort as to render it impossible for the patient to be up and about doing his work.

VERNAL CONJUNCTIVITIS AND EOSINOPHIL CELLS *

BROWN PUSEY, M.D.
CHICAGO

In 1903 Herbert[1] discovered the fact that the conjunctival secretion in vernal catarrh is rich in eosinophil polymorphonuclear leukocytes, and called attention to the bearing of this fact in diagnosis. Several observers have confirmed this discovery, in that they found tissue affected with this disease rich in these cells; and Peters[2] confirmed it by finding the cells in the secretion. Axenfeld, in his exhaustive study of the pathology of vernal catarrh, emphasized the importance of these cells in diagnosis and reported their presence in eight cases in one year. LaGrange,[3] Gabrielides,[4] Blaauw[5] and Lafon[6] have lately recorded cases of this disease with eosinophil cells in the secretion.

In the spring of 1910, two typical cases of vernal catarrh came under my care in which the secretion was rich in eosinophil cells. These two cases attracted my attention to the possibility of the importance of these cells in diagnosis, and I began examining smears stained with Giemsa taken from all the cases of conjunctivitis seen in my clinic and in private practice. I continued this during the spring and summer, and I venture to publish briefly the results of this work because from it I am convinced that Herbert's discovery has received too little attention, and that we therefore continue to overlook a disease which is much more frequent than is commonly suspected.

My series of cases included all the ordinary forms, etiologically speaking, of conjunctivitis—conjunctivitis from the common bacteria, as pneumococcus, staphylococcus, gonococcus, in adult and new-born, diplobacillus of Morax-Axenfeld; several cases from chemical irritants accidentally applied, as lime and alcohol; numerous cases of acute and chronic trachoma, in two of which trachoma bodies were found; numerous cases of phlyctenular conjunctivitis; six cases of conjunctivitis accompanying measles; and, as is usual in any series of cases of conjunctivitis, there was a number of cases of unknown etiology and no bacterial finding.

In the smears from the cases of conjunctivitis of known cause, including in these the cases of measles, eosinophil cells were very rare, only an occasional one being found. In the cases of unknown etiology and no bacterial finding it developed early in the work that in a number of them the conjunctival secretion was rich in eosinophil cells. This finding led to a more careful clinical observation, when it was discovered that clinically those cases rich in eosinophil cells agreed in every point with descriptions of vernal catarrh found in the standard text-books.

[6] Lafon: Examen cytologique et micro-chémique des sécrétions conjunctivales: Son utilisation en clinique, Ann. d'oculist., 1910, cxliii, 321.

Of the cases in which I was led to the diagnosis by the eosinophil cells in the secretion, there were ten; I also saw during the spring and summer three cases of vernal catarrh in which a proper diagnosis would have been made without attention to the presence of eosinophil cells, making a total of thirteen cases in a small clinic.

When it is realized that vernal catarrh is considered a rare disease, and that I recognized ten cases in a year directly as the result of Herbert's discovery, the importance of his observation in diagnosis of this disease is clear.

The experienced clinician will doubtless be surprised by the statement that thirteen cases of vernal catarrh were found in a small clinic in a year and when I found that I was seeing a case almost every week, and, indeed, one day saw two cases, I was troubled, fearing inaccuracy in my observations. However, in every case in which eosinophil cells were at all common, the objective and subjective symptoms agreed with those given in the standard text-books, and then the question came up as to the cause of the former failure in diagnosis.

I am strongly of the impression that the answer is simple and that we have not known the disease in spite of accurate, although ill-balanced descriptions of it. This is illustrated in that admirable text-book—that of Fuchs—under symptoms and course. The following passage occurs:

> The conjunctiva of the tarsus is covered with papillæ which are broad and flattened so as to make the conjunctiva appear like a pavement of cobblestones. Over the whole lies a delicate bluish-white film as if a thin layer of milk had been poured over the conjunctiva. The changes in the conjunctiva of the eyeball are still more striking. Growths arise from the limbus at the outer and inner side of the cornea under the form of brownish, uneven hard nodules of gelatinous appearance.

The above is found in his principal description of the disease. In a foot-note one finds in small print the following statement:

> The papillæ are often small or altogether absent, so that the bluish-white veil, which covers the conjunctiva of the tarsus, is the only evidence of the disease.

In the above description I believe I have relief from my fear of inaccuracy in observation, and the answer to the question regarding our former failure in diagnosis. We have heretofore made the diagnosis when papillæ existed and overlooked cases without papillæ. The cases with small papillæ or no papillæ at all are, I believe, the more frequent and it is in these cases that Herbert's observations will be of most service.

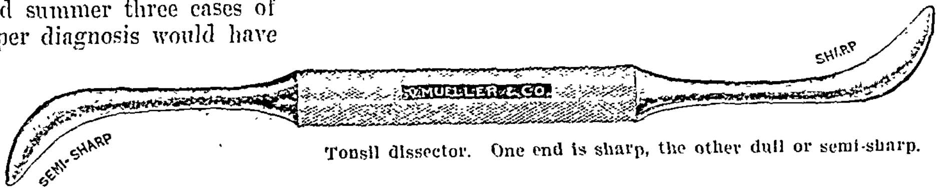
—70 Madison Street.

Overfeeding in Breast-Fed Infants.—A nursing mother admits hunger as the only cause of an infant's tears. The amount of milk which she supplies depends on the demands of the infant. The child's capacity for food is limited, but the instinct to suck prevails each time the breast is offered. Hence *among* nurslings overfeeding is rife and alimentary disorders common.—W. J. Maloney, in the *Practitioner.*

NEW TONSIL DISSECTOR

JOSEPH B. GREENE, M.A., M.D.
ASHEVILLE, N. C.

My excuse for adding a new instrument to an already large list of tonsil instruments is its simplicity, and adaptability to the removal of the submerged tonsils, and likewise the more or less pedunculated gland. As the illustration shows, the instrument has one semi-sharp or dull extremity, while the other end is sharp. The dull, or semi-sharp end is for blunt dissection in cases in which the adhesions to the pillars are not strong and fibrous, and in which the plica triangularis is not present. It is especially suited for the removal of tonsils in young children.



Tonsil dissector. One end is sharp, the other dull or semi-sharp.

It causes a minimum amount of bleeding, thus shortening the time of operation. The sharp end of the same instrument will be found useful in the buried and somewhat fibrous tonsils, or when the plica triangularis is prominent—a condition which requires cutting before the tonsil can be separated from the pillars.

I use this instrument to free the tonsil from its attachment as a preliminary to the use of the wire snare. For those who do not use the wire snare, however, the gland can be entirely removed by this instrument with the aid of a suitable retractor.

REPORT OF THIRTEEN CASES OF HEMIPLEGIA FOLLOWING HEAD INJURY *

EDMUND A. BABLER, M.D.
Junior Surgeon, Deaconess Hospital; Visiting Surgeon, City Hospital
ST. LOUIS

Hemiplegia due to cranial injury is perhaps of more frequent occurrence than we have been led to believe, although this complication was present in only thirteen of the 614 cases of fracture of the skull admitted to the City Hospital during the past five years. In two other cases there was paralysis of one leg, and in one case the side of the patient's face, opposite to the scalp wound, was motionless. A brief report of the cases in point follows the history of my own case.

AUTHOR'S CASE

CASE 1.—*History.*—G. P., colored, a laborer, aged 29, was admitted to the surgical department of the City Hospital, *Oct. 18, 1910.* Dr. Chaddock, visiting neurologist to the City Hospital, saw the patient with me. The patient was conscious and stated that two hours before admission he was struck on the right side of his head with a heavy hoe handle. On regaining consciousness one hour after the injury, he found that the left side of his body—that is, his arm and leg—was paralyzed.

Clinical Findings.—At the time of admission examination revealed a very large hematoma covering the greater portion of the right side of the patient's head. The pupils were equal and reacted to light and accommodation. Facial paralysis was absent; pain and tactile sense were absent in the left arm and leg; knee-jerks were present at time of admission, but fifteen minutes later the knee-jerk in the left leg had disappeared.

---

* From the St. Louis City Hospital.

The left leg and arm were paralyzed; the Babinski, Gordon and Oppenheimer signs were absent on both sides. There was absence of hemorrhage from the ears or nose. The pulse was 60, respirations 18, temperature 98 F. Dr. Kissel incised the hematoma and found an extensive depressed fracture of the right parietal bone, and involving the occipital bone.

Operation.—Under ether anesthesia, the usual incision was made and the depressed fragments elevated. Brain tissue escaped. The opening in the dura was enlarged and a subdural clot removed. The greater portion of the gray matter in the right Rolandic area seemed to have been crushed and destroyed by the injury. The removal of the fragments of bone was followed by a hernia cerebri. Examination of the right middle meningeal artery showed same intact. Dr. Chaddock concurred in the opinion that a basal hemorrhage was present. A piece of rubber dam was placed between the exposed white matter and the scalp and the operation wound closed with interrupted sutures. Two small drains of rubber tissue were placed in the lower angle of the wound.

Convalescence.—On the day following the operation, the patient stated that there was a slight return of sensation in the left side of his body, but he was unable to localize. There was a hypersensitiveness in the left supraclavicular and shoulder regions. The drains were removed on the third day. A grumous substance escaped from the wound for several days after the operation; examination of the substance showed it to be brain-cells and blood-cells. Ten days after operation the rubber dam was removed. Later the wound discharged a grayish liquid which showed destroyed brain-cells and staphylococci. The hernia cerebri became gradually smaller until at the time of the patient's discharge December 8 Dr. Hardaway noted that it was not prominent.

Return of Function.—As early as the first day after operation the patient appreciated a beginning return of function in the involved leg and arm. On the sixth day Dr. Kissel found that there was a slight return of tactile sense in the left leg; on the tenth day the patient could move his left leg, and on the following day he could move the affected arm but could not move the hand or fingers. From this date the improvement was very noticeable at each daily visit. Fifteen days after operation the patient was permitted to sit in a chair. November 15 Dr. Simon made a notation that the patient could walk and that the left leg and arm were functionating. The patient requested his discharge December 8. His condition was very good.

ADDITIONAL CASES

Case 2.—Patient unconscious; pupils unequal; right dilated; both reacted; paralysis of left side of face; also left arm and leg; no marks of violence on body. Patient died within a few hours.

Case 3.—Patient unconscious; pupils equal and reacted; tongue deviated to the left; hemiplegia on left; hematoma over right parietal bone. Operation showed hemorrhage from right and left middle meningeal arteries. Three weeks after operation there was a slight return of function on left side of body; patient had not fully regained function in limbs at time of discharge.

Case 4.—Patient unconscious; laceration of left parietal region; pupils equal and reacted; spasmodic twitchings of chest and face; paralysis of right arm and leg; pulse 60, respiration 28, temperature 102 F. Operation revealed epidural hemorrhage. The patient died.

Case 5.—Patient unconscious; had fallen ten feet; laceration found in left temporal region; paralysis of right side of body; pulse 84, respirations 28, temperature 98.6 F. Operation revealed a depressed fracture of the greater portion of the left parietal bone. There was an epidural clot present. Patient died.

Case 6.—C. C., admitted May 12, 1908, unconscious; hematoma in the mid-occipital region; pupils unequal; right pupil dilated; hemorrhage from right ear; complete paralysis of both arms and legs. A linear fracture of occipital bone, going toward the base, was found. Operation revealed laceration of the cerebellum. The patient recovered.

Case 7.—J. C., unconscious; pupils equal and reacted; pulse 68, respiration 18, temperature not stated. A hematoma was found situated in the region of the right parietal eminence. Incision showed a linear fracture. The Babinski sign was present on the right side. Operation revealed a linear fracture of the right temporal bone with presence of an epidural clot. The patient recovered.

Case 8.—S. C.; unconscious; pulse 100, respiration 24, temperature 99 F.; pupils unequal; right pupil dilated; both pupils reacted; eyes deviated to the left. Hematoma of the vertex was found and incised, revealing a depressed fracture. Operation was performed. The fragments of bone had caused a laceration of the longitudinal sinus. The patient died.

Case 9.—W. W., aged 64, unconscious; pupils were unequal; reacted. Incision of hematoma in left parietal region showed linear fracture in region of left parietal eminence. The patient recovered without operation. The condition of the paralyzed side of the body at time of discharge was not stated.

Case 10.—N. U.; unconscious; hemorrhage from right ear; pupils were unequal; deep reflexes absent on both sides of body; paralysis of left side of body. A depressed fracture of frontal bone was found, associated with a linear fracture of the base. Patient was operated on and recovered. Condition of paralyzed side at time of discharge was not stated.

Case 11.—The patient was conscious. A laceration was found in the right supra-orbital region; pupils were unequal and reacted sluggishly; Babinski's sign was present on the left side; paralysis of left arm and leg. Operation showed a depressed fracture of the frontal bone, with presence of an epidural clot in the parietal region. The patient recovered.

Case 12.—Patient unconscious; pupils contracted and fixed. A hematoma situated in the left parietal region was incised and a depressed fracture found. There was a paralysis of the right side of the body. The patient died shortly after admittance.

Case 13.—M. G., unconscious; pupils equal and reacted; pulse 122, respirations 22, temperature 101; paralysis of right side of body. Patient talked incoherently; died within a few hours after admission.

COMMENT

It is surprising to what extent the brain may be crushed and compressed without producing focal signs or permanent paralysis. Hemiplegia following cranial injury is a very serious complication. Six of the thirteen patients died, although the mortality of the patients operated on was only 33⅓ per cent. Ransohoff's[1] mention that the prognosis of fracture of the skull is more favorable in the conscious patients is corroborated by the findings in six hundred cases studied. Only two of the hemiplegic patients were conscious at time of admission, and both recovered. On the contrary, however, the patient with a fracture may be admitted in a conscious condition and thirty minutes thereafter may become dazed and lapse into unconsciousness and die within ten minutes. This is especially true of the patients who are partially intoxicated.

In two of the thirteen cases the fracture and the paralysis were on the same side of the body. Four of the patients presented equal pupils that reacted to light. In four cases the pupils were unequal but both pupils reacted. It is interesting to note that only two of the patients presented a hemorrhage from the ear and both recovered. The development of paralysis following cerebellar laceration is worthy of mention. The treatment of hemiplegia following fracture of the skull is too well known to require comment. Early surgical intervention saves the most lives.

HYPERPLASTIC TUBERCULOSIS OF THE CECUM AND COLON

REPORT OF CASE

N. P. WALKER, M.D.
MILLEDGEVILLE, GA.

Cases of hyperplastic tuberculosis of the cecum are still rare enough to be of interest; hence the following case is recorded.

Patient.—F. H., colored woman, aged 30, was admitted to the State Sanitarium Aug. 15, 1905; weight 121 pounds; height 5 feet 10 inches; pupils rather small but react normally; patella reflexes increased; pulse temporarily increased; some suppression of breath sounds over left apex; abdomen soft and lax; external genitals congested; laceration of the cervix and perineum. Mental diagnosis, dementia præcox. The patient was inclined to be seclusive and did not enter into voluntary conversation as a rule. She took no interest in her surroundings and was untidy, but not filthy. The family and personal history as obtained from the patient was not reliable. The following notes were made on physical condition from time to time.

Course of Disease.—Feb. 12, 1906: Chain of enlarged glands on left side of neck extending down behind the clavicle; expansion lags on left; no râles; no known cough or night sweats. Temperature 98.6 to 100.4 F. in axilla. Tuberculous adenitis and suspected pulmonary involvement.

Feb. 17, 1906: Diminished expansion; slight elevation of percussion note and harsh breath sounds over left apex; no râles; some enlargement of glands on both sides of neck and under chin; feet somewhat swollen; liver dulness increased downwards; urine showed trace of albumin; occasional hyaline cast; few pus cells.

Feb. 29, 1906: Irregular elevation of temperature; the patient did not cough during the daytime; some blood-stained sputum found in her room in the morning; temperature 101 F.; positive diagnosis of pulmonary tuberculosis made and patient removed to the tuberculosis ward. Weight, 88 pounds.

March 3, 1906: For the past several days temperature was 96.4 F. (axilla); pulse 88 to 100; respiration 14 to 18.

March 28, 1906: Some non-localized pain in abdomen; bowel movements normal; considerable amount of fluid in abdomen which was apparently partially encysted. The patient was confined to bed, but there was no edema of face, feet, or hands; pleuro-pericardial rub; faint systolic murmur heard at the aortic interspace.

June 8, 1906: There was considerable improvement in general condition of patient; abdomen rather flabby but apparently contained a small amount of fluid; glands in neck were not quite so large; some physical signs over left apex; no fever or cough.

From above date the patient presented no symptoms of active pulmonary lesion and the abdomen became apparently normal. Owing to urgent need of room on the tuberculosis ward the patient was removed to the regular wards on March 4, 1907. The glands were still somewhat enlarged, but the pulmonary lesion had been in state of arrest for many months. The abdomen was apparently normal. From the first month of treatment on the tuberculosis ward until the patient was removed one year later there was a gradual and marked increase in weight each month. At time of removal she weighed 172 pounds, a net gain of 84 pounds.

Jan. 15, 1908: The patient was put to bed one week since on account of dysentery; stools numbered five or six per day and contained blood and mucus. Emaciation was marked; slight cough and night sweats. Physical examination of the chest was negative.

Aug. 5, 1908: The patient put to bed about one month since on account of condition of bowels. The stools at first contained some blood and mucus. This quickly disappeared, but the number of movements continued from two to four daily and were watery in character. The liver dulness extended almost to the level of the umbilicus. On the right a tumor mass was felt. It was about 2½ inches above and slightly to the inner side of the anterior superior spine, its upper margin being on a level with the lower margin of the umbilicus. The mass was hard, somewhat irregular in outline, and only slightly tender. It could be moved upward, downward, and inward to the extent of about two inches each way. It was apparently a growth connected with the cecum. There were marked emaciation, cough, night sweats, and fever chiefly at night; temperature reaching 101. A few fine and moist râles were heard over the left apex. Diagnosis, recurrence of pulmonary tuberculosis; abdominal tumor; probably tuberculosis of cecum. The patient was removed to tuberculosis ward; weight, 85 pounds.

From the above date until June 20, 1909, there was a slight but steady gain in weight at which time the patient weighed 114 pounds. From June until the day of operation, Feb. 12, 1910, there was some fluctuation in weight, with a net loss of three pounds.

During this interval the patient was kept in bed the greater portion of the time. There was no diarrhea, the bowel movements being normally formed. The patient vomited only a few times, usually at night. She was given light diet in addition to milk. On one occasion the patient vomited dinner about ten minutes after its ingestion. The tumor became more tender and the patient often complained of pain in the region of the mass.

Operation.—Feb. 12, 1910, an operation was performed by Drs. Garrard and Cline. The following note was made by Dr. Garrard: "Mass in right side found to be very strongly adherent to the parietal peritoneum. The mass delivered with difficulty in the median line, the friable intestine being opened in doing so. Cecum with portion of ascending colon resected. The ileum and ascending colon united with Murphy button. Drainage with rubber tube. Operation lasted two hours and ten minutes. Patient removed from table with pulse 140. The walls of the excised intestine were greatly thickened. The opening in the intestine was about the size of an ordinary pencil."

Macroscopic Examination of Specimen.—Pathologic report by Dr. J. H. Hewitt: "The specimen consists of a cecum and a portion of the ascending colon, the whole being about 15 cm. in length. The wall of the intestine is markedly thickened, especially as to its mucosa and submucosal tissue. In the upper portion there is an indurated fibrous mass the size of a robin's egg."

Microscopic Examination.—"The mucous surface shows the tubules moderately thinned out and great increase in intertubular connective tissue and round-cell infiltration. The wall is swollen and edematous and more or less infiltrated with small round cells. In several places along the border-line between the submucosa and the circular muscular layer there are collections of epithelioid cells surrounded by a ring of small round cells. Along the border-line between the epithelioid and round cells, and in among the round cells are several giant-cells. The muscle layers are swollen and edematous and more or less infiltrated with round cells. The peritoneal coat is thickened. It shows collections of small round-cells and giant-cells. Diagnosis: Chronic typhlitis; interstitial tuberculous typhlitis; chronic adhesive tuberculous peritonitis."

Postoperative History.—Convalescence was protracted and tedious; pulse often reaching 150; temperature 101.4 F. February 13, it gradually declined until normal was reached on the 14th. February 20 pus was found to be present in the wound; but temperature did not go above 99.4 F. The button was removed from the rectum on March 11. On March 17 it was believed that a small abscess had formed in abdominal wall and a counter-incision under *cocain* was made. A fecal fistula resulted. The temperature again rose and reached 101.4 F. on March 18. From this date there was a gradual decline until normal was reached on March 20. There was only a very slight rise in the pulse-rate.

On May 20 the patient was again returned to the tuberculosis ward; weight 106 pounds. There were two fistulas present. The one following the second operation healed in a short time.

Jan. 4, 1910: The patient's weight was 140 pounds; glands in neck barely palpable; limitation of expansion over left apex;

friction sound heard at the sternum in the third right interspace, also heard in the axilla; both fistulas open; very slight discharge. Liver dulness extended three fingers' breadths below costal cartilage; there was a hard nodular mass about the size of a walnut in left iliac region; the abdomen was full, rather prominent; some tenderness over the region of the uterus.

Jan. 24, 1911: General nutrition was good; no subjective complaints; abdomen prominent; non-sensitive; the nodular mass in left side still present; both fistulas healed; bowels *normal*.

I believe that the initial lesion began almost four years before operation. Diarrhea was not present for several months prior to operation. Alternation of constipation with diarrhea appears to be the rule in such cases. Vomiting was infrequent, which appears to be rather remarkable when the degree of stenosis is considered. The colon was markedly thickened at the point of resection, and the probability of further stenosis is to be considered. Pain was not such a prominent feature as is usually the case. The patient's mental condition may account for this in part, however.

OBSCURE CASE OF TRAUMATIC SUBDURAL HEMORRHAGE WITHOUT FRACTURE

MEYER SOLOMON, M.D.
Junior Assistant Physician, Government Hospital for the Insane
WASHINGTON, D. C.

In his article on "Pathology of Intracranial Hemorrhage" Spiller[1] says: "Subdural hemorrhage has been more frequent in my experience than epidural, and I have repeatedly seen a hemorrhage beneath the cerebral dura as a result of injuries to the head in cases where the skull was not fractured. This occurrence is important to remember, and sometimes the discovery of the subdural hemorrhage comes as a surprise to the operator."

DaCosta[2] says that subdural hemorrhage is usually due to depressed fracture and rupture of the middle meningeal artery, or of a number of small vessels.

According to Church and Peterson,[3] Cruveilhier asserts that in one-third of the cases of asphyxiated new-born, subdural hemorrhage is the main difficulty. The clots are commonly found over the convexity, and are, in surviving cases, a pregnant source of idiocy and cerebral palsy.

According to DaCosta,[2] "most cases of cerebral palsy seen in children are the result of subdural and subarachnoid hemorrhage at birth, and damage of the cortical motor area. The hemorrhage, in cases of birth palsy, is, as Cushing points out, usually venous and due to 'rupture of some of the delicate and poorly supported venous radicles of the cerebral cortex.' It may result from traumatism due to bone overlapping or forceps pressure during parturition, or may arise during asphyxia after birth."

In examining still-born infants and infants that died shortly after birth, Cushing[4] found that many of them died with cortical hemorrhage. In some cases the extravasations found were very large—even completely overlying the cerebral hemisphere, while in others they were found to be much smaller. In one case the clot was found in the cerebellar fossa. It was found that the vessels were most usually torn on only one side and were the unsupported radicles which enter the longitudinal sinus; hence the cortical leg center of one side is most apt to be seriously damaged. When, however, the vessels of both sides are torn, a bilateral cortical lesion results.

Cushing himself,[5] speaking of traumatic subdural hemorrhage in adults, says:

> Bleeding in the free space between the dura and arachnoid is possibly a more common consequence of injuries than the extradural form. It is a frequent complication of basal fractures, for, owing to the close attachment of the basal dura these injuries almost always tear the membrane so that the bleeding from the fissured bone has free access to the subdural space. Similarly, fractures of the vault, accompanied by laceration of the dura, lead to extravasations over the hemisphere. The extravasation, however, *may occur from an injury* of some cortical or leptomeningeal vessel in cases of fracture with laceration of the brain, or, indeed, in the absence of any demonstrable cranial lesion.

He also points out that the usual type of such extravasations is a diffuse one, this being particularly so in its basal form. The blood spreads through the open subdural space, and as the arachnoid membrane overlying the basal cisterns is frequently torn by the injury the bleeding extends over the brain stem and down along the cord, where the subarachnoid space is open, and no a closely confined meshwork as it is over the hemisphere For this reason free red blood-corpuscles in the cerebrospinal fluid will often be found on lumbar puncture Cushing adds, however, that, "although this diffuse form of bleeding is perhaps the most common, as well as the most critical type of subdural hemorrhage, one no uncommonly sees, particularly over the hemispheres extravasations in this space, which have remained circumscribed owing to the rapid clotting of the blood.' These subdural extravasations are usually of venou rather than of arterial origin.

The symptoms of a subdural hemorrhage, accordin to Cushing, differ but little from those associated wit an acute increase of intracranial tension from any cause "Although in the rarer cases of intracranial and superficial clot formation, there may be localizing signs pointing to the seat of the process, the symptoms are usuall those of a generalized compression." The lesion, h continues, results from a serious cranial injury, and th clinical picture is one of cerebral contusion with cor pression. We find the patient unconscious, medulla symptoms almost always present, the blood-pressure h during the early stages, the pulse slow, the respirati labored, and, as stupor passes into coma, Cheyne-Stoke breathing sets in, and finally the paralytic stage o compression comes on.

It is on account of the free extravasation into th subdural space that most of the cases of basal fractur prove fatal. In some instances, however, the amount o extravasation may be so slight, that, although blood fluid may be obtained on lumbar puncture, no reall serious pressure symptoms are produced. A choked dis is said to be almost always present.

It must be remembered, however, that although th symptoms of subdural hemorrhage are identical wit those of extradural, they are usually very rapid in onse and are accompanied by a more distinct drop in temperature and graver depression. No focal symptoms ar produced unless the hemorrhage arises from or presse on the motor area, when convulsions, or later, paralysis may ensue.

[4] Cushing: Intracranial Hemorrhage in the New-Born, Am. Jour. Med. Sc., October, 1905

[5] Cushing: Surgery of the Head, Keen's Surgery, 1907, ii 206-209.

In brief, the main points in favor of a diagnosis of subdural rather than extradural hemorrhage are:

1. Subdural hemorrhage is the most common form of intracranial hemorrhage in the new-born.
2. It is frequently associated with depressed, and more especially, with basal fractures of the skull.
3. It is characterized by an absence of the periods of concussion and "free interval," and by the rapid onset of symptoms.
4. The symptoms are usually those of a generalized compression, with marked depression and unconsciousness, practically from the very first, and the almost invariable presence of medullary symptoms.
5. The presence of blood in the cerebrospinal fluid on lumbar puncture.

A case somewhat similar to mine is reported by Cushing. A patient was injured in a football scrimmage. There was primary concussion, followed by an actual "free interval," and the appearance of focal symptoms which pointed toward a local compression over the left lower central convolution. A diagnosis of extradural hemorrhage was, of course, made. Cushing's favorite intermusculotemporal operation was performed. No fracture of the base could be demonstrated, nor was there any extradural hemorrhage found; but there was a subdural lens-shaped clot analogous to an extradural hematoma. Removal of the clot led to prompt recovery. Cushing says that cases of this sort, however, are rare, and the surgeon is usually confronted with extensive basal extravasation.

The case of traumatic subdural hemorrhage here reported is one of more than usual interest because of the following points:

1. The occurrence of a primary injury which caused a simple incised wound of the scalp and probably resulted in nothing more than a momentary stunning.
2. The presence of a "free interval" of unusually long duration (*ten days*) from the original injury to the onset of the first symptoms of compression. This initial injury and the subsequent "free interval," are, it is to be noted, considered characteristic of extradural bleeding, but have here occurred in subdural hemorrhage.
3. The absence of any fracture of the skull.
4. The absence, except for dilated, immobile pupil on the side of the hemorrhage, of any definite focal symptoms which might have given a clue to the location of the hemorrhage, although as found post mortem, the hemorrhage was practically localized to the convex surface of the frontal lobe, with extension backward to the region of the occipital lobe.
5. The localization just described.
6. The finding at autopsy of the presence of almost completely fluid blood—which may be accountable for the last-mentioned condition.
7. The absence of macroscopic blood in the excessive basal cerebrospinal fluid.

Unfortunately a lumbar puncture was not performed, but this, as proved by post-mortem findings, would have been free from any blood.

REPORT OF CASE

History.—M. G., a white man, aged 37, for past five years has been a patient in the Government Hospital for the Insane, suffering from the katatonic form of dementia præcox. He would wander mischievously and annoyingly about the ward, picking away stupidly and mutely at the other patients.

Oct. 29, 1910, at 8:15 a. m., in a scuffle with a fellow-patient, our patient was forcibly shoved, and in falling, struck his head against the sharp edge of a heavy wooden settee, receiving a simple incised wound of the scalp about one inch long, just above the right temple. It did not require stitching and was apparently not associated with fracture. The area about the wound was shaved, the wound thoroughly cleansed, and a collodion dressing was applied. The patient did not seem stunned at the time of the injury and continued to be up and about in the ward as usual.

When he went to bed on the evening of November 7, he seemed to be in his usual physical condition. When taken out of bed for dressing on the morning of November 8 (ten days after the scalp wound was received), the patient seemed to be very weak and so was put back to bed by the attendant in charge. A little later he had an attack of vomiting; temperature was 97 F. by axilla, pulse 60, regular and full, respiration 14. At 8 a. m. he seemed to be very dull; his legs and arms jerked slightly and his breathing was labored. At 11 a. m. he was semiconscious, resistant, and held his arms rigid; knee-jerks were active, pupils normal. The patient passed urine and feces involuntarily. Intracranial hemorrhage was suspected. Hot soapsuds enema was ordered. At 12 a. m. temperature was 96.6 F. by axilla, respiration 24, pulse 60.

Patient grew more and more stuporous and gradually lapsed into deepening unconsciousness. At 4 p. m. he was absolutely unconscious; both pupils were fixed and failed to react to direct light; right pupil markedly dilated, tendon reflexes active, extremities limp, skin sensation lowered. Babinski reaction obtained now and then on both sides, but irregular in response. Respiration very slow (12), regular, quiet, but deep. Pulse down to 50 per minute; regular in rate and force; full volume; temperature by rectum, 96.2 F.; bed was wet from involuntary evacuation of urine. Patient could not be aroused. The entire scalp was shaved, but examination failed to reveal any signs of fracture. The scalp wound received ten days previously almost healed. A positive diagnosis of intracranial hemorrhage was made, but the exact site of the hemorrhage was not determined. Operation was proposed to the patient's wife, but she refused consent.

At 6:45 p. m. temperature by rectum was 97.6 F., pulse 48, full, regular, and strong, respiration 15, deep, quiet and regular. Examination at this hour showed lacrimation from right eye, signs of hemorrhage from nose on right side (clotted blood being found in right anterior nares), but no signs of fracture of nose, so far as could be detected; pupils still absolutely fixed, the right being considerably dilated, the left somewhat contracted. Ophthalmoscopic examination of right eye showed outline of disk distinct and sharply defined, with no hemorrhages. Skin reflexes were almost absent; elbow and knee-jerks increased on both sides; no ankle- or patellar clonus. The Babinski phenomenon now showed an even more marked, peculiar variability and irregularity, being present first on both sides, then more on one side than the other, and then vice versa, only to change again. Sensation was very much delayed. Very deep pin-pricks were required to elicit a response, and then only after an unusually long period. Contralateral adductor reflex could be obtained by stroking the skin on the inner side of the thigh on either side. There was a tendency on the part of the patient, to stiffen the extremities and rotate them inward, bringing the knees and elbows together. There was an intermittent tremor of the right hand, and a tendency to contract the quadriceps extensor. Kernig's sign was absent. The patient lay absolutely calm and perfectly unconscious; breathing not stertorous.

At 1 a. m. the patient's condition was unchanged, but after 2 a. m. he began to weaken; his pulse became feeble, respiration was down to 6, and death occurred at 3:40 a. m.—only twenty-two hours after the first symptoms were observed.

Necropsy.—The bladder was somewhat distended; the colon very much distended throughout. The spleen and kidneys were somewhat congested. The cardiovascular and respiratory systems seemed normal. There was a scalp wound about one inch long, one inch to right of middle line, on a line with the zygoma. This did not extend through the scalp for more than one-fourth its thickness. There was no fracture of the skull in any part, although after removing the brain, the dura was stripped and the base of the skull carefully examined.

Brain: On the right side, over the convex surface of the brain, there was a flat subdural hemorrhage. Both the dura and the pia-arachnoid were intact, but the pia-arachnoid was very much engorged. The bleeding vessels could not be found, but the blood was almost wholly fluid, with some slight, fresh soft clot, and it seemed to be mainly of venous rather than arterial origin. The blood did not extend to the base nor on to the mesial surface, being confined mainly to the convex surface of the frontal lobe, though extending backward in a thin layer, nearly to the occipital lobe. The surface of the frontal lobe, especially about its middle, was considerably depressed. This depression was so marked, that, as a result, the right ventricle was very much flattened, and contained but little cerebrospinal fluid, while there was an excess of fluid at the base, about the origin of the pons. This fluid was perfectly clear and contained no blood. There was no laceration of the brain surface, and, on sectional examination, no intracerebral injury was found.

ELECTRIC TREATMENT OF INTESTINAL OBSTRUCTION AND POSTOPERATIVE PARALYSIS OF THE BOWEL

WILLIAM H. DIEFFENBACH, M.D.
NEW YORK

Intestinal obstruction and postoperative paralysis of the bowel are of such grave moment that a clinical note on this subject offering a new technic in its treatment has warrant for its publication. The method consists essentially in the employment of half-normal saline enemas in conjunction with a hollow rectal electrode connected with the galvanic current, followed later, if necessary, by faradization.

The conditions in which this treatment is useful are as follows:

1. Chronic constipation with impaction of feces.
2. Atony of the bowel.
3. Traumatic, localized and general peritonitis with intestinal stasis.
4. Intestinal torpor after shock.
5. Slight volvulus or kinks in the bowel after prolonged manipulation, and chilling of the bowel following laparotomies.
6. Intestinal paralysis after prolonged meteorism.
7. Intestinal paralysis following various forms of hernia.

The conditions in which the treatment is of doubtful or negative value are the following:

1. Intussusception.
2. Stricture of the bowel.
3. Adhesive bands about the intestines.
4. Malignant growths involving the bowel.
5. Tumors impinging on the lumen of the intestines.

In these cases surgery must be invoked, and the electric treatment can be subsequently employed for its stimulation on peristalsis.

TECHNIC

1. The nurse prepares the bed with rubber sheets and padding to prevent leakage to the mattress, and a moderately flat and long bed-pan is placed under the buttocks.

2. While the preparation is going on it has been my custom to advocate lavage of the stomach with a quart of weak saline solution (half-normal strength) at 105 F. so as to clear the stomach of mucus, bile or other debris, and check vomiting, which is usually present in these cases. Lavage also has a tendency to start downward peristalsis, especially if a small amount of liquid is left in the stomach for absorption.

3. Three or four quarts of one-half strength normal saline solution at a temperature of 105 to 110 F. is prepared and kept hot on a radiator or stove.

4. The rectal electrode, well lubricated, has attached to its distal end the rheophore connected with the negative pole of the galvanic battery and the central orifice of the electrode connects with a Davidson syringe. The electrode is introduced into the rectum as far as it will go and one quart of the fluid is slowly injected.

5. A large sponge or felt electrode, at least 4 by 6 inches, well moistened in sterile or mild antiseptic solution, is connected with the positive pole and placed over the right hypogastrium so as to cover the ascending colon, and an assistant makes firm and even pressure on it, and if necessary remoistens the electrode. This pole may be shifted to the transverse colon and in some cases to the descending colon, but in the latter case its sphere of action will be over but a small portion of the bowel.

6. The galvanic rheostat is slowly moved until 10 to 15 M.A. are registered; after three minutes of electrolysis with liberation of chlorin ions which tend to relax tissues, the pole is reversed and the pole-changer kept going for from five to ten minutes more, reversing every thirty seconds. This interruption of the current produces marked contraction of the whole musculature of the abdomen and intestines and usually produces peristalsis and a desire for evacuation. If this desire is strongly expressed, the electrode can be temporarily removed and the patient given a chance to evacuate feces or expel gas. Unless the evacuation has been eminently satisfactory, some more of the saline is again injected, and following the interrupted galvanic treatment, the attachment of the rheophores is made to the high-tension faradic coil and the current manipulated through the secondary coil so as to produce a gradually increasing, then diminishing, contractile effect. The faradic treatment is given as strongly as the patient can stand without much distress, and is continued for five minutes. The withdrawal of the electrode is then usually followed by expulsion of fluid, feces and gas.

7. After the electric treatment, the bed-pan is removed and the head of the bed elevated so that the patient is placed in an inclined position of from 25 to 45 degrees, so as to favor normal peristalsis. This is an important point in technic and should not be omitted. This position has been maintained in several cases for three days before recurring meteorism was checked.

8. Following the treatment, normal saline retention enemas, one quart at 105 to 110 F., are given every two hours until normal conditions supervene.

9. Repetition of the treatment is necessary in many cases. In one case which refused to respond, the sixth treatment, given after repeated failures during forty-eight hours, at last caused profuse evacuation. It is usual, when the condition is grave, to rest the patient for three hours before repeating the treatment. In chronic constipation or impaction a longer period (six to twelve hours) may be permitted to elapse before repeating the course of treatment.

I have been called to a large number of these patients when they were practically *in extremis*, and when all varieties of enemas, stupes and drugs had been tried. Even in such desperate straits the electric enema has, in a fair percentage of cases, proved successful.

It cannot be emphasized too strongly that the earlier the electric enema is given in all cases, the better the prospects for success. When meteorism develops and bowel movement is not produced by the usual enema and other remedies, every hour lost with the use of turpentine, alum, asafetida and other enemas merely weakens the reactive power of the bowel and renders regeneration by means of the electric current more difficult.

The battery used in these cases consists of a twenty-four dry-cell apparatus with galvanic and faradic (high tension) attachments, rheostat and milammeter, and is readily portable to the bedside.

1748 Broadway.

BACILLUS AEROGENES CAPSULATUS INFECTIONS, WITH REPORT OF TEN CASES

WALTER R. HEWITT, M.D.
Resident Physician, St. Louis City Hospital
ST. LOUIS

This infection is interesting because of the high death-rate and the frequency with which the condition is overlooked until too late for surgical interference. It is looked on as a rare condition, though it is more frequent than one would suppose. There have been three cases at the City Hospital since June 1, 1910, with three recoveries.

To Maissonneuve and Pirogoff is due the credit for the first clinical descriptions of the disease. Maissonneuve, writing in 1853, called the disease *gangrène foudroyante,* but it was not until 1891 that Dr. Welch discovered and described the organism. There has been much confusion as regards this organism and its pathologic processes, even the latest text-books giving little space to a clear description of this definite infection and its danger to life.

The most frequent sources from which the organisms may be obtained are the intestinal tracts of mammals and the soil, although Welch (1896) recovered it from a bullet in the head of the tibia.

The organism (*Bacillus aerogenes capsulatus*) normally grows in the absence of oxygen, although Lahey[1] demonstrated that the *B. a. c.* may grow on culture media in the presence of oxygen.

SYMPTOMS

There seem to be three principal types of the infection; namely, simple, fulminating, and mixed.

The incubation period, as nearly as could be ascertained in ten cases, was forty-eight hours. In one case it was twenty-one hours (Case 10). In the simple cases, there is slight rise in temperature and pulse, the patient appears seriously ill, and there is a dark, almost black, bloody discharge, which resembles a thin syrup. This discharge usually brings out a few small bubbles, and leaves us wondering what infection is present. *Pus is not present.*

The fulminating or malignant type depends on the severity, virulence and site of the infection, and not only affords the best opportunities for study of pathologic processes, but soon convinces one that something radical must be done and done quickly. In this type the patient is usually found with high temperature (103-104 F.) and rapid pulse (130-150), with rapid respiration (30-40 per minute), and appears critically ill. *B. a. c.* infection occurs most ofen after injuries in which tissues are pulpified and very dirty. About forty-eight hours afterward, when the wound is dressed, a dark, thin, syrupy, foul-smelling discharge escapes with gas bubbles.

The fulminating type on the leg may take on the appearance of an erysipelatous condition, though without raised borders, there being a dark or brownish discoloration. This was the condition in Case 7, plus a lymphangitis, which was at first deceptive. Blebs of variable sizes are frequently present and soon take on a blue or greenish appearance. When opened, the characteristic, foul-smelling fluid with its sweetish odor, becomes apparent. If an extremity is involved, it rapidly becomes gangrenous and distended with gas of a composition of hydrogen 64.3, carbon dioxid 27.6 and nitrogen 8.1 (burning with a pale blue flame). This was the clue to the diagnosis in Case 9, although the diagnosis was suspected from the early rise in temperature (first twenty-one hours) and the history of injury. Cultures will show the presence of organism, but with a clear clinical picture operation should be undertaken at once.

Pain was absent in all except Case 10. Here the patient's pain became very great, and as he was not furnished relief by morphin, after three attempts to get consent to operation had failed, he finally consented to amputation, which was done, and he recovered. (Blake and Lahey explain the absence of pain on the ground of the necrosing action of *B. a. c.* interfering with nerve conductivity, although the presence of gas and distention, as I believe, with its mechanical effect, must not be forgotten. A sort of anesthesia is produced.)

Delirium occurs late, after the general infection, and persists till death. In Case 4, delirium was so great that diagnosis of delirium tremens and infection was made.

Within seventy-two hours, toxemia is pronounced, and I agree with Blake and Lahey that recovery is not the rule after the third day.

Nausea and vomiting occur late, and, like delirium, are indicative of generalized infection.

The process extends chiefly by direct extension, as the gas separates and dissects between muscle and fascial planes and follows the lines of least resistance.

The lymph-glands are seldom enlarged and tender, and only when other organisms are present, as the streptococcus (Case 10). The rapidity with which the process ascends a limb probably accounts also in part for the frequency of non-involvement of lymph-glands.

Emphysema or crepitus was elicited in Cases 2, 3, 4, 5, 7, 8 and 9, and in one case gas escaped with a noise. In Case 1, a tympanitic note was elicited on percussion.

Fascia, tendons and ligaments resist infection strongly. Muscle, especially pulpified muscle, affords a flourishing site for the infection. At the wound site, the tissues are soft, friable and pulplike: while beyond, the tissues are pale and edematous, contain small amounts of gas, and are rapidly being converted into a pulpified state.

Mixed infections, whether streptococcus or staphylococcus, in which infection remains at the site of inoculation, are usually mild.

TREATMENT

Treatment is always operative unless there is a generalized infection.

In the presence of general infection, the free opening of the wound, with hydrogen peroxid as a dressing should be tried. If a leg or thigh is involved, spinal anesthesia may be used.

There are, however, two recognized methods of treatment—amputation and multiple incisions. *Amputation* is the operation of choice in all malignant cases, as it offers good chance for recovery. What one of us would care to treat such cases with multiple incisions and hydrogen peroxid in view of the fact that oxygen does not always kill the organisms (Lahey) and in these cases the organisms are far from the original site of the wound and hydrogen peroxid cannot reach them. Of course, in a simple case, multiple incision and hydrogen peroxid might be tried, and even oxygen carried into the wound with catheter. Under careful observation if amputation is performed when advance takes place, recovery may be expected.

---

[1] Blake, J. B., and Lahey, F. H.: Infections Due to the Bacillus Aerogenes Capsulatus, The Journal A. M. A., May 21, 1910, p. 1671.

Of course, an occasional limb may be sacrificed with amputation, but what when we try multiple incisions and find later a dead patient?

In my series of cases, three patients recovered (all in cases of malignant type and developing within forty-eight hours) after amputation, one leg and two arms being sacrificed. In cases recovering under multiple incision and hydrogen peroxid treatment, might not there be some other gas-producing organism?

In this series of cases, Patient 3 was of necessity treated with multiple incisions, as the infection involved the trunk. The patient promptly died, as infection was general.

PROPHYLAXIS

Ordinary antiseptics, tincture of iodin, bichlorid, etc., have little or no effect on the organism, as I have seen cases develop after vigorous treatment with these antiseptics.

CASE REPORTS

CASE 1.—H. H., a carpenter, aged 56 (No. 5776), was admitted Nov. 16, 1906. This patient was accidentally shot November 18 in a tent while on a hunting trip. He was treated by Drs. Taylor and Pickel of Festus, Mo., who forwarded him to St. Louis for treatment. The patient's condition when seen by them was as follows:

"The soft tissues were nearly all shot away just above the ankle. Both bones were badly shattered. The foot was connected with the leg only by a narrow strip of skin and some fragments of muscle. It was not dressed in any way except in the blanket that the patient was lying on. There was no dirt in the wound, more than would naturally get into it from the bedding, which was not very clean. There had been no attempt made to control hemorrhage; consequently he had lost about all that he was able to stand. He was in a state of considerable shock, so that only a trimming of the remaining shreds of tissue was performed, and bleeding points ligated. No attempt made to disinfect the wound, other than to apply a 2.5 per cent. solution of phenol (carbolic acid) and get him to the hospital as soon as possible.

The doctors at Festus were of the opinion that the infection came from the blanket in which his leg was wrapped.

When he arrived at the St. Louis City Hospital, it was found that he had a ragged amputation of the left leg four inches above ankle-joint, with much laceration of soft tissue and comminution of bones. The patient arrived at the hospital at 8:30 in the evening, having been injured about eleven in the morning of the same day. Hemorrhage had ceased when he arrived at the hospital. The leg was shaved and cleansed, put in a large saline pack without much effort to trim away the ragged tissues. Patient complained of weakness and thirst; pulse was almost imperceptible; temperature subnormal. Salt solution, by hypodermoclysis was given; external heat; patient placed in bed; antitetanic serum given; condition bad; pulse 120, respirations 24, temperature 97.2 F. Urinalysis revealed the presence of albumin and a great many hyaline and finely and coarsely granular casts.

Within twenty-four hours after the accident, amputation was performed in the middle third of the leg, the circular flap method being used. After being in the ward sixteen hours, a peculiar, stinking, sweetish odor was noticed about the patient, and on dressing the wound it was found to be discolored. Blood-culture was positive.

On the night of November 18 the patient was beginning to show symptoms of general infection, pulse 150, respiration 50, very shallow and mostly abdominal. The patient complained of pain in the abdomen and over the epigastric region. The abdomen was distended and soft, and over the left lower quadrant was a soft, fluctuating crepitus. The same condition was present over the left thigh, but in a more marked degree. The surgical wound with its dressing was not disturbed.

The patient at 3 o'clock in the afternoon complained of great difficulty in breathing. At 3:25 p. m. the patient was sinking rapidly, the heart failing to respond, although he was delirious and trying to get out of bed. The patient lost consciousness about 4 p. m., showing evidences of air-hunger, gasping for air. The heart-beat was not palpable; small, thready pulse. Patient died at 4:22 p. m., November 19, three days after admission.

This was a very virulent infection, traveling up the leg very rapidly. In a few hours, it had extended up as far as the neck, death following. Post-mortem findings were as follows:

Gangrenous emphysematous stump, universal emphysema of the subcutaneous tissues, emphysema of the heart, lungs, liver, kidneys and spleen, acute enlargement of the spleen, congestion and edema of the lungs, and a foamy condition of organs.

This case is interesting as showing another source of infection: that of a gunshot wound; it also shows that great loss of blood and pulpification of tissue influence an early appearance of the infection on account of the patient having practically no resistance. The case was an early, malignant type with general infection.

CASE 2.—M. N., a laborer, aged 41 (No. 6642), entered Nov. 30, 1907, with a history of having been run over by a locomotive. As a result, both legs from a few inches below the knees to above the shoe-tops were pulpified. The wounds were dirty. An emergency trimming operation was performed. Pulse at this time was 106, respirations 24, temperature 99 F. Antiseptics used in first-aid treatment were bichlorid, tincture of iodin, and turpentine.

On the morning of December 3, patient developed a high temperature, rapid pulse and signs of severe shock. Bichlorid pack was applied at this time. On the morning of December 4, an offensive, characteristic sweetish odor was present. There was some emphysema of the left thigh. The left thigh at 3 p. m. was greatly distended and tympanitic on percussion. At 6 p. m., the left limb was tense with gas, the gas being found subcutaneously between the fascia and muscle and up in the left groin, and it extended in the midaxillary line nearly to the axilla. Numerous incisions were made, and the gas escaped with a noise. At this time, a bichlorid and turpentine dressing was applied, with a diagnosis of emphysematous gangrene. The patient died at 8:55 p. m., five days after admission, of a general *B. a. c.* infection (clinical).

The patient had become very delirious on the evening of December 3, and delirium persisted until death.

This case is interesting, as it shows the effect of a general infection and the rapidity with which the process advances when it has once started.

CASE 3.—R. S. (permit No. 6701), schoolboy, aged 12, entered Dec. 2, 1907, at 4:40 p. m. The patient gave a history of falling off of a wagon three days previous to entrance, suffering a fracture of the tibia in the upper third, and a long, lacerated wound on the posterior surface of the calf of the left leg. The leg presented a sharply defined, bluish color extending from the ankle to the knee anteriorly and about 2 to 3 inches above the knee on the inner surface. The entire area was studded with blebs, from which a foul-smelling, greenish discharge was escaping. The wound had been closed on the outside by a physician. In the right groin was an area of discoloration 2 by 8 inches, and over the right great trochanter was an abrasion dressed with gauze covered over with collodion. Palpation of the left thigh and groin elicited distinct crepitation—emphysema. The patient died December 3, at 4:12 in the morning, four days after the injury. Delirium in this case appeared on the third day and lasted until the end.

This case shows the effect of sealing dirty wounds and of not observing such a case closely. The clinical diagnosis was made, but there was no report of a blood-culture.

CASE 4.—J. H., a packer, aged 51 (permit No. 5321), was admitted to the hospital Oct. 22, 1908, at 11:05 a. m. He entered the division suffering from an old, compound fracture of the radius and ulna, nervous and very delirious. The diagnosis at this time was delirium tremens and compound fracture of the radius and ulna.

The arm was dark-brown in color, emphysematous throughout, and a foul-smelling discharge was escaping, but no pus. The characteristic sweetish odor was present.

Later, *B. a. c.* infection was added to the diagnosis; blood-culture positive.

The patient died Oct. 22, 1908, at 12:50 p. m. Emergency treatment was given, but could not be extensive in view of the fact that he was suffering from generalized infection.

The comment which I would make on this case is that it brings out the point that the delirium and nervousness may be so great as to cause confusion as to whether or not the patient has delirium tremens.

CASE 5.—D. C., a carriage-worker, aged 56 (permit No. 2657), admitted July 3, 1909; entered the St. Louis City Hospital with a history of severe traumatism, and as a result had a laceration of the head and right shoulder; the right hand was also badly crushed, showing evidence of pulpification, the dirt of the street being ground into the extremity. Blood-culture was positive. The patient died July 7, 1909, at 1:20 p. m., with delirium, nausea, vomiting, nervousness and all the signs of a general infection.

Consent to amputation was not obtained until the second day. Amputation was performed at the lower third of the right forearm with circular incision; skin approximated with three sutures. Drainage. A reduction of the shoulder was performed at this time. The next day ecchymosis was present about the wound, stitches were removed and thorough drainage instituted. On the fourth day, the forearm was badly swollen, discolored, crepitation of the tissues, bacteriologic examination showing presence of the gas bacillus. Incisions were made in the gangrenous area and the arm placed in a saline bath, the patient thoroughly septic.

This was a case, evidently, in which the ecchymosis deceived the physician who was treating the case and in which a high amputation would probably have saved the life..

CASE 6.—J. C. (permit No. 3395), a trackman, aged 45, entered the hospital July 28, 1909, at 11 a. m., suffering from severe crushing injuries of both feet, produced by falling under a moving freight train. He also had a fracture at the middle of the left leg.

Twenty-four hours after entrance, the limb was amputated about seven inches below the knee-joint by the long posterior and short anterior flap method, with careful ligation of vessels and resection of nerves. The skin-flaps were approximated with interrupted silkworm-gut sutures, with provisions for free drainage. The patient was in bad condition at the time of operation, hypodermoclysis being necessary. Moist dressing was applied.

Within thirty-six hours after admission, the symptoms of sepsis (namely, delirium, nausea, and vomiting) appeared. The patient climbed out of bed, and it was necessary to restrain him. The following morning, signs of gas bacillus infection were very evident, the parts being dark, discolored, distended with gas, bubbles escaping, along with a black, bloody discharge. Blood-culture was positive. The antiseptics used in this case were mercury bichlorid, 1-2,000. The patient died July 30, 1909, at 9:40 p. m., nearly sixty hours after entrance.

CASE 7.—F. T. (permit No. 5626), a laborer, aged 20, entered the hospital, Oct. 4, 1909. He gave a history of being hurt in a street-car accident. He had a crushing injury of the left thigh, was in extreme shock, and his condition did not permit of immediate amputation.

Two days after admission, his general condition had improved somewhat, although sepsis was extreme. The leg was very dark, beginning to become gangrenous. It was distended and full of gas. The patient was unable to stand a general anesthetic and, accordingly, with a long, sharp, amputation knife, the calf muscles were severed at the point of fracture, about four inches below the knee-joint, vessels ligated and moist dressing applied. The patient died Oct. 8, 1909, four days after admission.

Like those in the previous cases, this patient died with all the evidences of a general infection, his case being one of those in which the patient could not have stood a high amputation.

CASE 8.—J. P. (permit No. 1868), aged 26, a driver, entered the hospital June 9, 1910, giving a history of being hurt in a runaway. The history of the accident as obtained later from the patient was that the street was an improved one and was very muddy. Examination revealed three lacerated wounds on the middle third of the right leg, with a compound, comminuted fracture of both bones of the left leg in the lower third, with numerous abrasions and contusions of the left foot. There were a few abrasions on the right leg.

Treatment at this time was directed to cleansing and shaving the limb, followed by an alcohol pack and iodin. The leg was placed on a Cabot splint and 1,500 units of tetanus antitoxin administered.

Some twenty-four hours after patient's admission, the temperature rose, pulse became very rapid and the patient complained of some pain. Examination at this time revealed a dark, spreading inflammation, not sharply circumscribed, and without elevated borders. There was bleb formation, and the leg presented signs of beginning gangrene. It was of a dusky color, or brownish hue, and in view of the fact that the patient's leg had been thoroughly rubbed in the dirty street, with the clinical signs as above, we believed that we were dealing with a gas bacillus infection. Cultures were taken, sent to the laboratory, and the following day were reported positive.

Without waiting for report from the laboratory, it was decided that, in order to give the patient a chance for his life, it would be necessary to do a high amputation at the junction of the lower and middle thirds of the thigh. Under a general ether anesthesia, the operation was performed by the circular cuff method. The wound was closed in layers overlapping the bone and two rubber tubes inserted for drainage. The patient left the table suffering from considerable shock. The wound was irrigated daily with hydrogen peroxid, and a hydrogen peroxid dressing applied. The process reached to the junction of the upper with the middle third of the leg, therefore it was necessary to go above the knee-joint.

The patient was discharged June 22, 1910, having made an uneventful recovery.

CASE 9.—W. B. (permit No. 5877), aged 60, a pipecutter, entered the hospital Oct. 20, 1910, giving a history of having been injured by an elevator. Examination showed the right hand almost entirely torn from the arm at the carpal joint. The skin was torn loose around the entire wrist. All the muscles, tendons and nerves were severed, along with most of the vessels on the anterior surface, only those tendons on the posterior surface being intact. The hand was cold and sensation was abolished. The wound was cleansed and skin flaps loosely approximated in the hope that there might be an establishment of circulation. Pulpification of the hand was great.

When first seen by me two days after admission to the hospital, when the hand was dressed, it was found that the tissues presented an appearance very much like that of a gas bacillus infection. The hand was becoming dark in color; there was a foul-smelling, sweetish odor, with a dark, bloody discharge, and a few gas bubbles. Two hours after this, amputation was performed, the hand beginning to crepitate. The anteroposterior flap method was carried out at the junction of the lower with the middle third of the arm. On the following morning, after the operation, the patient's temperature was normal and he was doing well. Healing occurred by first intention, patient being discharged November 21, after having remained in the hospital for three weeks preparatory to finding a home.

Case 10.—G. Y. (permit No. 7853), a laborer, aged 25, entered Dec. 31, 1910. The patient was suffering from a compound fracture of the forearm with laceration and crushing of forearm. There was considerable pulpification.

Temporary treatment was given, but in twenty-one hours gas with a gangrenous process appeared. The forearm was very dark in color and gave off a foul, sweetish odor. There were gas bubbles in the tissues, as shown by crepitation and also by the escape of bubbles. The patient had a high temperature, rapid pulse, was septic and complained of considerable pain.

The patient was informed of his condition on three occasions, it being necessary after thirty-six hours to bring the influence of his relatives to bear on him to obtain consent to operation. It was explained to him, at the time of operation, that the question of saving him was very doubtful on account of the delay.

Under general anesthesia, an anteroposterior flap at the junction of the upper and middle third was made in the usual way. Closure was with interrupted silkworm-gut sutures after irrigating the wound thoroughly with hydrogen peroxid. A rubber tube was inserted in each corner of the flap, and thereafter was daily irrigated with hydrogen peroxid and hydrogen peroxid dressing was applied.

Within twenty-four hours, the patient's temperature had dropped to normal, followed in thirty-eight hours by a rise due to an infection of the wound with a probable staphylococcus infection. All sutures were removed, and hydrogen peroxid and tincture of iodin were freely used. The wound, two weeks after amputation, was clean but required a repair amputation.

In this case, a gas-producing organism was found which in culture media produced gas, but an attempt to segregate it met with failure, although the clinical evidence was unmistakably that of a gas bacillus infection with some contamination with the staphylococcus.

CONCLUSIONS

Early interference, before seventy-two hours, preferably amputation in malignant cases involving extremities, in most cases will mean the saving of life.

Laborers and railroad men are prone to infection, as their wounds are often contaminated with soil.

Infection occurs most frequently from contamination with street dirt, followed by railroad dirt, then elevator dirt, and then intestinal tract discharges. The frequency of street soil infections, I believe, can be explained on ground of contamination with manure. There are two recorded cases in which infection occurred in ischiorectal abscesses, the rarity, it is thought, being due to the fact that these wounds usually are wide open and lined with a layer of granulation tissue, the granulation tissue preventing the free dissection of the gas and the oxygen probably preventing the *B. a. c.* infection.

All wounds contaminated with street or railway dirt should be observed for this infection and treated, if possible, in such a manner as to permit of easy inspection. Hence plaster casts and sealing of wounds should be avoided. Cultures should be made if there is a suspicion of *B. a. c.* infection, and the wound freely opened and treated with hydrogen peroxid or oxygen preparatory to amputation, if necessary. In Case 10, the amputation stump was irrigated through drainage tubes with hydrogen peroxid twice daily for the first two days, although at the time of operation the wound was flooded repeatedly with hydrogen peroxid.

Fall in temperature to normal would seem to indicate the eradication of *B. a. c.* infection, as in Cases 9 and 10.

The disease is only relatively common, as it has occurred at the city hospital on an average of once in about 1,250 surgical cases, and practically always in cases in which there was pulpification of tissues. Since *B. a. c.* infections do not develop in very many or most cases of soil and street contaminated wounds (though often found here), it would seem that pulpification of tissue and injured blood-supply favor *B. a. c.* infection, owing to weak or absent resistance. There is further evidence to this effect, as shown in reported cases with presence of gas bacillus on and in amputation stumps.

Brewer has found that diabetics are prone to infection, and experimentally the *B. a. c.* develop more easily and rapidly in the presence of sugar.

Early diagnosis by definite, clean-cut, clinical pictures, and prompt, radical treatment will materially reduce the death-rate.

Blood-cultures should be made in every case, but treatment should not wait.

I believe that the condition is often unrecognized, and trust that this report will stimulate an interest that will result in more frequent diagnoses of the infection.

AN IMPROVED APPARATUS FOR ESTIMATING THE PRESSURE IN THE CEREBROSPINAL SYSTEM

BURRILL B. CROHN, M.D.
Volunteer Assistant, Pathological Laboratory, Mount Sinai Hospital
NEW YORK CITY

Since the introduction by Quincke[1] of an apparatus for estimating the cerebrospinal pressure, there have been numerous criticisms of the mechanics of the instrument and several attempts have been made, either to modify his apparatus, or to introduce a new principle. As devised by Quincke, the apparatus consists of the ordinary puncture needle and trocar, to which is attached a long piece of rubber tubing leading to an S-shaped piece of bent glass. According to the height to which the latter has to be raised the pressure is estimated, the reading being taken from the level of the hilt of the needle to the level of the fluid in the glass tube; this is measured by an independent centimeter scale.

The imperfections in the use of this instrument are the following:

First, between the time when the trocar is withdrawn from the needle and the moment when the rubber tubing is attached to the hilt of the latter there must necessarily be an escape of fluid, even providing that the worker is rapid in his actions and the connections are all firm and watertight. This loss of fluid, which is inevitable, and which may vary from 1 to 5 c.c. when the pressure is high, affects the accuracy of the reading. Secondly, the length of the rubber tubing and its usual large caliber, causes it to act in part as a reservoir, a long loop of this tubing frequently hanging far below the level of the needle. The latter, therefore, often withdraws from the estimation as much as 5 c.c. of fluid. When the pressure is low this interferes materially with the attempt to read intraspinal pressure.

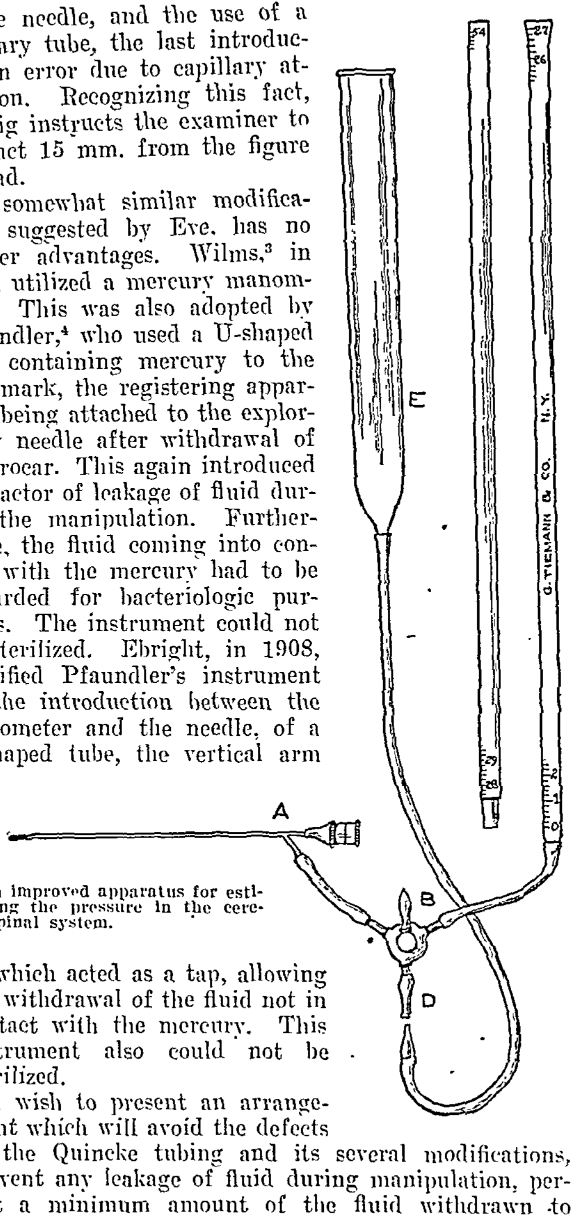
The advantage of the instrument is that it permits a reading to be made before and after withdrawing the fluid, and allows examination of the fluid without dilution with another second inert fluid such as might be used in a manometer.

---

[1] Quincke: Technik der Lumbal Punction, 1902; Deutsch. Klin., 1906, vi, 351.

In 1897, Krönig[2] introduced a modification of the apparatus by inserting into the needle after withdrawing the mandrin, a short L-shaped glass tubing the upper arm of which acted as a scale on which to read the height to which the intraspinal pressure forced the fluid; the horizontal arm was employed to withdraw a specimen for examination or for therapeutic purposes. In addition, he incorporated in the needle a stop-cock, by means of which he could prevent the leakage of fluid while he was attaching his manometer. The disadvantages of this instrument are its rigidity, the complexity of the needle, and the use of a capillary tube, the last introducing an error due to capillary attraction. Recognizing this fact, Krönig instructs the examiner to subtract 15 mm. from the figure as read.

A somewhat similar modification, suggested by Eve, has no further advantages. Wilms,[3] in 1897, utilized a mercury manometer. This was also adopted by Pfaundler,[4] who used a U-shaped tube containing mercury to the zero mark, the registering apparatus being attached to the exploratory needle after withdrawal of the trocar. This again introduced the factor of leakage of fluid during the manipulation. Furthermore, the fluid coming into contact with the mercury had to be discarded for bacteriologic purposes. The instrument could not be sterilized. Ebright, in 1908, modified Pfaundler's instrument by the introduction between the manometer and the needle, of a T-shaped tube, the vertical arm of which acted as a tap, allowing the withdrawal of the fluid not in contact with the mercury. This instrument also could not be sterilized.



An improved apparatus for estimating the pressure in the cerebrospinal system.

I wish to present an arrangement which will avoid the defects of the Quincke tubing and its several modifications, prevent any leakage of fluid during manipulation, permit a minimum amount of the fluid withdrawn to register the pressure, and facilitate the withdrawal of all the fluid uncontaminated and in an unaltered condition. ~~The~~ principle which Quincke introduced, i. e., that the pressure should be estimated by the height to which the fluid is raised in a vertical tube, is utilized.

The apparatus consists of the following parts: (a) a needle, the hilt of which bears a terminal cap firmly screwed on; at about 2 cm. distant from the posterior end is a small branching arm, the lumen of which is the same as the lumen of the needle proper; (b) a three-way stop-cock made of metal; (c) a graduated piece of heavy glass tubing 30 cm. long with a lumen of 2 mm.; a second tubing of the same length and capacity is used, which has a tapering ground-glass lower end by which it may be fitted into the upper end of the first tube when the pressure is unusually high. The three-way stop-cock is interposed between the graduated glass tubing and the branch arm of the needle, connection being made on each side by a piece of rubber tubing 2 cm. long. The third arm of the stop-cock is used for the withdrawal of the specimen. A blunt trocar accompanies the instrument; if the needle is inserted in the canal without a flow of fluid resulting there is suspicion that the lumen may be blocked by tissue, the cap of the needle may be unscrewed and the trocar inserted to reestablish the patency of the needle. The trocar should only be used for this contingency.

The technic required for the manipulation is as follows:

First, the entire instrument is sterilized by boiling in water.

Second, the needle is attached to the three-way stop-cock, the latter being closed so as to prevent premature escape of fluid and the registering glass tube being disconnected temporarily.

Third, the operator holding the stop-cock in the palm of his hands, grasps needle and performs puncture according to his own way or preference for this maneuver.

Fourth, the point of the needle being felt to lie freely in the spinal canal, the registering glass is now attached to the second arm of the stop-cock by means of its connecting rubber tube; the handle of the stop-cock is turned to the first position, allowing the free escape of the spinal fluid into the registering apparatus.

Fifth, the pressure having been read, the handle of the stop-cock is turned to its second position, allowing the escape of the fluid from the registering tube into the collecting vessel; then turned into its third position allowing the further direct escape of spinal fluid into the collecting vessel. After the proper amount of fluid has been obtained the handle of the stop-cock is turned into its first position and the pressure again estimated. After the final pressure has been read, the needle is withdrawn from the spinal canal. The retained fluid is washed out with running water and the apparatus is resterilized.

A glass funnel and small-bore connecting rubber tubing about 20 inches long is furnished for injection of therapeutic serum or solutions when so desired. The tubing is attached to the third arm of the stop-cock (that used for withdrawing fluid) and the funnel lowered until cerebrospinal fluid replaces the air in the tubing. The injection fluid is then poured into the funnel, the latter raised, and the fluid allowed to enter the canal.

The instrument presents the following advantages:

First, there is no opportunity for accidental escape of fluid.

Second, the apparatus is compact and small, the entire capacity of the registering apparatus being only 60 minims.

Third, the instrument can be thoroughly sterilized.

Fourth, no foreign substance is used to indicate pressure. The registering part is made of heavy glass not easily broken; the stop-cock is of metal, simple and durable; the short rubber connecting parts can be easily replaced when the elasticity is exhausted.

[3] Wilms: München. med. Wchnschr., 1897, p. 55.
[4] Pfaundler: Beitr. z. klin. Med. und Chir., xi, 20.

For comparison of the readings with that of a mercury manometer it is necessary only to recall that dividing the result in millimeters by the factor 13.6 will give the equivalent pressure as estimated by a column of mercury.

The reading with this instrument should be comparable to those obtained with the Quincke apparatus. The same principle of physics applying to each.

In a very short series of about twenty-five cases the following readings were taken: Normal seemed to lie between 2 and 6 cm.; incipient tabes dorsalis 10 cm.; multiple sclerosis 17 cm.; suppurative meningitis, from 10 to 30 cm.; *tuberculous meningitis, from 30 to 60 cm.*

The same regulations that appertain to all lumbar punctures must be observed; it must be remembered that the position of the patient, whether sitting or prone, struggling or crying, is very important in their effects on the cerebrospinal pressure. But as these variations refer in general to all methods of lumbar puncture, it is not necessary to discuss them here.

75 East Eighty-First Street.

ANEURYSM OF THE EXTERNAL PLANTAR ARTERY [*]

CHENEY M. STIMSON, M.D.

AND

J. TORRENCE RUGH, M.D.

PHILADELPHIA

This case is reported because it is somewhat of a surgical curiosity. In looking up the literature, aneurysm of the external plantar artery is found to have been reported five times.

Masson[1] in 1868, Cutliffe[2] in 1872, Gross[3] in 1874, Johnson[4] in 1874, and Gangitano[5] in 1904 report each a case. There have also been reported a few cases of aneurysm of the dorsalis pedis and of the internal plantar artery. Although the plantar surface of the foot is subjected, perhaps, to more pressure than is any other part of the body, the arteries, by reason of the dense fascia and the arch of the foot, are no more exposed to traumatism than are other arteries of the extremities.

Patient.—C. L. A., a man aged 34, married, was first seen Aug. 6, 1910. He complained of continuous dull pains, worse on walking, in the sole of the right foot. The pain was so severe that he walked with great difficulty with the foot in the equinus position. The trouble had commenced six months before as a slight, aching pain, intermittent, later becoming continuous and increasing. At the time the patient consulted us he was unable to perform his duties, which were those of a traveling salesman. The patient's father died of chronic nephritis at 67; mother, two brothers and two sisters are living and well. His wife and two children are living and apparently healthy. His wife has had two miscarriages. There is no history of cardiac or malignant disease or of tuberculosis. The patient had measles, chicken-pox and typhoid fever in childhood, pneumonia at 18. Concussion of the brain at 31 disabled him for six months. He denied venereal infection.

Physical Examination.—The patient was a well-nourished man apparently aged 35 and weighing about 140 pounds. Aside from moderate arteriosclerosis and a somewhat accentuated aortic second sound, his physical condition except for the present trouble, was good. The arch of the right foot was almost gone, the foot being flat, and on the plantar surface directly beneath the instep, nearer the external side was a round, pulsating tumor 5 cm. in diameter and protruding 2 cm. beyond the surrounding surface. The pulsations were synchronous with the radial pulse and there was a well-marked bruit.

Operation.—Operation was performed at the Methodist Hospital, Aug. 8, 1910. The sac was exposed and found to be spherical in shape and 3 cm. in diameter. The artery on each side of the sac was ligated and the sac removed. The patient made a good recovery and was able to return to his work in four weeks.

1801 Cayuga Street—1616 Spruce Street.

Therapeutics

CARDIAC TONICS OF MINOR IMPORTANCE

ADONIDIN, CONVALLARIA, CACTUS GRANDIFLORUS, SPARTEIN, APOCYNUM CANNABINUM, BARIUM CHLORID

None of the above-named drugs can compare in efficiency or activity with digitalis and strophanthus. While most of them have been shown to have the ability to stimulate the heart to greater contractions, it has not been shown experimentally or clinically that they have any advantages over digitalis in small doses, and as compared with large doses of digitalis they are much inferior. If digitalis or strophanthus does not agree with a patient, and produces undesirable symptoms, the dose is probably too large or too frequent, and the substitution of a weaker drug is not the substitution of a better drug, but is a demonstration of the misuse of the digitalis or strophanthus. There is no good reason why any of these drugs should be official in the next Pharmacopeia.

A description of these drugs and their activities, and the conditions for which they have been used are as follows:

ADONIDINUM. ADONIDIN

Description.—Adonidinum, genitive adonidini, is an active glucosid obtained from *Adonis vernalis* or *Adonis autumnalis* (false hellebore), a plant native of Northern Europe and Asia. This glucosid was isolated, in 1882, by Cervello, of Strasburg, and is an amorphous, inodorous and very bitter substance, soluble in alcohol, very slightly soluble in water.

Local Action.—This drug has no special local action.

Systemic Action.—The action of adonidin has not been very carefully worked out except on the circulatory system. In very large doses it seems to be somewhat irritant to the gastro-intestinal mucous membranes, producing vomiting and diarrhea. Its action on the heart muscle and on the cardiac nerves is similar, though less powerful, to that of digitalis. After a first slight increase of cardiac action it slows the beat, prolongs the diastolic rest, and raises the blood-pressure by causing contraction of the arterioles. Poisonous doses, after the primary slowing of the heart, cause it to beat very rapidly, probably because of paralysis of the vagi. Later the blood-pressure falls and the heart action becomes very slow. The drug acts somewhat as a diuretic, probably on account of the increased blood-pressure.

Action of a Therapeutic Dose or the Primary Physiologic Action.—It slows and strengthens the heart, raises the blood-pressure, and slightly increases the output of urine; in other words, it has a similar action to that of a physiologic dose of digitalis. The toxic symptoms are practically the same as in digitalis poisoning, and the treatment is the same as for poisoning by that drug.

---

[*] Read before the Jefferson Clinical Society, Jan. 27, 1911.

[1] Masson: Mém. Soc. d. Sc. méd. de Lyons, 1868, vii, 26.

[2] Cutliffe: Indian Med. Journal, Calcutta, 1872, vii, 248

[3] Gross, S. D.: Philadelphia Med. Times, 1874, iv, 391.

[4] Johnson: Boston Med. and Surg. Jour., 1874, xc, 115.

[5] Gangitano: Riforma medica, 1904, xx, 421.

Therapy.—Adonidin may be used as a substitute for digitalis whenever a cardiac tonic is indicated, but it is not so effectual in its action and cannot restore compensation as does digitalis. Adonidin has been used with bromids in epilepsy. There seems no more reason for its use in epilepsy than for the use of strophanthus. Any cardiac drug may be of marked value when the system is debilitated by bromids.

The contra-indications are the same as those for digitalis.

Administration.—Adonidinum is an expensive, nonofficial drug. The dose is from 0.01 to 0.02 gram (from $^1/_6$ to $^1/_3$ grain), best given in capsules as the solution is intensely bitter, administered every four or five hours. This drug acts much more quickly than digitalis, and hence could be used as a cardiac tonic in emergencies, but strophanthin is better. This drug probably has no cumulative action.

CONVALLARIA, U. S. P.: LILY OF THE VALLEY

Description.—Convallaria, genitive *convallariæ* (*Convallaria majalis*) is a native plant of the United States, Europe and Asia, and is also cultivated for its sweet-smelling flowers. The parts official are the rhizome and the roots which should be collected in mid-summer and dried in the sun. It contains a bitter glucosid, convallamarin, in acrid purgative glucosid, convallarin, and a resin. These active principles were discovered by G. F. Walz and described in 1859. Convallamarin is the principle which acts on the heart, the convallarin acting only as a slight purgative.

Local Action.—This drug has no noticeable local action.

Systemic Action.—The principal action of convallaria, through its constituent convallamarin, is on the circulatory system, and the action on the heart is similar to that of digitalis, though this action is not so sure and not so decided. It raises the blood-pressure somewhat and often acts as a decided diuretic. Whether this diuretic action is due to the improved circulation or to stimulation of the kidneys has not been decided. In non-poisonous doses there is a slight laxative effect but no marked purgative action.

Action of a Therapeutic Dose or the Primary Physiologic Action.—This drug is of doubtful action on account of the varying strength of its official preparation, but the action of a therapeutic dose should be slightly to slow the heart and strengthen its muscular action, to raise the blood-pressure slightly, to act as a mild laxative but not to disturb the stomach or digestion, and to cause a marked increase in the amount of urine.

Toxic Symptoms.—These symptoms would be similar to the symptoms produced by poisonous doses of digitalis, and the treatment would be the same as in poisoning by the latter drug.

Therapy.—The therapeutic use of this drug first began, unprofessionally, in Russia, as a remedy in dropsy, and later investigations gave it a professional standing as an active drug in cardiac debility and as of special value in cardiac edema. Therapeutically, then, it may be tried as a substitute for digitalis or strophanthus when there is valvular disease, a dilated or irregular heart and a tendency to cardiac edema. Though some therapists find the drug of great value in these cases its action is often disappointing, probably from the varying strength of its preparations.

Contra-Indications.—The contra-indications are the same as those of digitalis, and much gastric or bowel irritation should preclude its use.

Official Preparation.—The only official preparation is: Extractum Convallariæ Fluidum, the beginning dose of which is 0.5 c.c. (8 minims).

Unofficial Preparations.—Convallamarin occurs as an amorphous powder, yellowish in color and of bitter taste, soluble in water and alcohol. The dose is 0.05 gram (¾ of a grain) four or five times in twenty-four hours. Hypodermatically the dose would be about 0.02 gram (⅓ of a grain). The drug in emergencies, however, is greatly inferior to strophanthin. Convallarin occurs as a yellowish, amorphous powder, of acrid taste, insoluble in water, soluble in alcohol. It has no action on the heart, but may act as a laxative. The dose is about 0.2 gram (3 grains).

Administration.—The dose of convallaria should be pushed to some slowing of the heart and noticeable increase in the urine unless purgation should occur. There seems to be no cumulative action from this drug.

This drug could well be deleted from the Pharmacopeia.

CACTUS: NIGHT-BLOOMING CEREUS

Description.—Cactus, genitive *cacti* (*Cactus grandiflorus*) is a native plant of tropical America, and is cultivated for its beautiful flowers. It is not official, and no active principle of the plant has been obtained. A fluidextract and a tincture have been used medicinally. These preparations have been made from the fresh stalks, which contain an acrid juice.

Local Action.—The expressed juice of this plant is irritant and can produce vesicles and pustules on the skin, and when taken in concentrated form it causes pain, vomiting, and diarrhea.

Systemic Action.—Rubini, in 1868, was perhaps the first to state that a tincture of this plant was of advantage in cardiac debility. This has been reiterated clinically at stated intervals ever since. It has been clinically stated that the drug would increase the strength of the cardiac contractions and regulate the rhythm. It has also been stated that it would raise the blood-pressure. It has been stated experimentally that it acts on the intracardiac ganglia, and also that it is a stimulant to the vasomotor center. On the other hand, repeated recent careful experimentations with the best preparations obtainable, and that could be made from the crude drug, and experiments with so-called active principles have shown absolutely no physiologic activity whatever, and no action on the heart or blood-vessels. Favorable reports of circulatory activity of this drug found experimentally have probably been based on preparations of other allied plants, or contaminations. The drug and its preparations are therefore pharmacologically inert, and should not receive official recognition.

Toxic Symptoms.—An over-dose of a concentrated preparation of cactus would undoubtedly cause vomiting and other symptoms of gastro-intestinal irritation, and the treatment would be that of a gastro-intestinal irritant.

Therapy.—There is no reason or excuse for expecting any action on the circulation or any other part of the body from preparations of this plant. Any results obtained from the administration of its preparations are due to the associated action of something else administered or done at the same time. If a strong alcoholic preparation is used, the results obtained may be attributed to the action of the alcohol. The results obtained from the administration of preparations of this plant are purely psychical, or show that the digitalis, which was given to the patient before the cactus was administered, was not indicated.

This is a truth that cannot be too frequently repeated. A weak and useless preparation is substituted for a strong and active one; the patient or his symptoms improve; the results are recorded as activities of the useless, inert preparation, when the improvement is really the removal of the active drug which he did not need.

Also, there is the never absent psychical effect on the patient of a change of drug or the use of something decidedly different or unusual.

It should be accepted as an axiom that a drug that has no action on animals has no action on man.

SPARTEINÆ SULPHAS, U. S. P.: SPARTEIN SULPHATE

Description.—Spartein is an alkaloid obtained from *Scoparius* (broom). It is a colorless, oily, unstable liquid of intensely bitter taste, alkaline reaction, and anilin-like odor. Its neutral sulphate is the only preparation official, and is like all sulphates of the alkaloids, bitter and soluble.

Action on the Circulatory System.—The evidence of investigators and clinicians in regard to the action of spartein is so conflicting that it must be concluded that the actual action and utility of this drug is not established. It seems to be pretty thoroughly proved that spartein is a depressant to the nervous system and in full doses weakens the heart. There is, if any, only a short-lived rise in blood-pressure from spartein and in full doses the blood-pressure is diminished. It is depressant to the heart muscle, and in large doses paralyzes the peripheral endings of the pneumogastric nerves allowing the heart to become more rapid. Small doses, by stimulating the pneumogastric nerve, can prolong the diastole of the heart, and in certain cases may quiet and steady an irregular heart.

Action of a Therapeutic Dose or the Primary Physiologic Action.—The ordinary action from therapeutic doses of this drug should slightly slow the heart, regulate its rhythm, prevent its nervous irritability, slightly diminish the pulse tension, and moderately increase the output of urine.

Toxic Symptoms.—This drug causes symptoms of depression and paralysis similar to that produced by conium, and the treatment of poisoning would be the same as for the latter drug.

Therapy.—This drug is not a substitute for digitalis and does not act as does digitalis. The indications for its use are irregularity and nervous irritability of the heart, especially when conjoined with general nervousness. Spartein has been used in asthma, and it has seemed of advantage in disturbed cardiac action when combined with arteriosclerosis and chronic interstitial nephritis. Nitroglycerin and iodids, however, are safer and act better. It is not a diuretic. It is the scopalin of the broom plant that is diuretic.

Contra-Indications.—These are muscular or fatty degeneration of the heart, low pulse tension, dilatation of the heart; or acute cardiac weakness should prohibit the use of this drug.

Administration.—The only official preparation is sparteinæ sulphas, and the beginning dose is 0.02 or 0.03 gram (1/3 or 1/2 grain) given every six or eight hours, in solution or in capsule. The action of the drug is rapid, occurring in from 20 to 40 minutes.

There seems no good therapeutic reason for recognizing this drug in the revised Pharmacopeia.

APOCYNUM, U. S. P.: CANADIAN HEMP

Description.—*Apocynum*, genitive *apocyni* (*Apocynum cannabinum*). The part official is the rhizome. This plant should not be confused with *Apocynum androsaemifolium*, as the latter drug has properties different from the official drug. Preparations are probably, however, often made from the wrong apocynum, consequently the results are different. A non-glucosidal, crystalline principle has been isolated named apocynin.

Local Action.—The drug has no external action, but is an irritant to mucous membranes and readily causes vomiting, purging, and severe gastro-intestinal irritation.

Systemic Action.—This drug has long been used in dropsical conditions, especially in cardiac edema. It has also been used in ascites, and in hepatic cirrhosis with consequent disturbance of the circulation and edema of the lower part of the body and lower extremities. Good preparations from true *Apocynum cannabinum* have been shown to raise the blood-pressure and stimulate the cardiac muscle to stronger contraction. The diuresis caused by apocynum is doubtless more or less due to the improved circulation, and the diuresis is similar to that caused by digitalis. The pulse is slowed by stimulation of the vagus nerves, such action being similar to that of digitalis. Whether it has a specific stimulating action on the kidneys, causing increased secretory and excretory activity besides that caused by improved circulation, has not been determined. While its action has been noted clinically to be satisfactory, it is so frequently irritant to the stomach that for this reason its utility is impaired.

Action of a Therapeutic Dose or the Primary Physiologic Action.—The action of this drug is uncertain and the dose is uncertain, depending on the activity of the preparation procured. The desired and expected action would be to slow the pulse, to strengthen the heart, to raise the blood-pressure, and to increase the output of urine. Undesirable action is to cause gastric irritation, nausea and vomiting.

Toxic Symptoms.—These would be the same as would be caused by a gastro-intestinal irritant. By administration by the mouth it has not been shown that this drug could seriously injure the heart. Large doses would doubtless too rapidly cause vomiting to allow systemic poisoning.

Therapy.—Apocynum has been repeatedly reported clinically to be of value in general anasarca and in ascites. If there is cardiac defect its action and efficiency certainly cannot be compared to that of digitalis. In cirrhosis of the liver it is an undetermined question whether it would be any more valuable than other diuretics. When the drug has been pushed it has been noted that some congestion of the kidneys has been caused. It would be a question, when such kidney congestion occurs, whether it is not due to other causes than the drug.

Contra-Indications.—The contra-indications are gastro-intestinal irritation, and especially a tendency to nausea and vomiting.

Official Preparation.—The only official preparation is Fluidextractum apocyni; dose 1 c.c. (15 minims). The powdered drug itself may be administered, if desired, in lose of 1 gram (15 grains). Administration of the rude drug, however, would be senseless, if a reliable luidextract were available.

Unofficial Preparations.—Apocynin may be obtained oth as the crystals and in an amorphous form. The rystals are white. The amorphous form occurs as a white or yellowish-white powder, and contains a resin. Both are soluble in alcohol. A tincture of apocynum may be obtained, the dose of which would be about 1 or 2 c.c. (15 to 30 minims).

Apocynum androsaemifolium (dogbane), sometimes called the wild or mild ipecac, has been used in chronic constipation, but it is irritant. The dose of the fluidextract is about 1 c.c. (15 minims).

Administration.—The best preparation is undoubtedly the fluidextract, but the activity of this drug and preparations, as above stated, is uncertain. The only excuse for its use is as a diuretic in dropsy. The drug has been used as an emetic, but such use is inexcusable. Other emetics are better and more certain.

It would be well to omit this drug from the Pharmacopeia unless it can be assured that the *Apocynum cannabinum* is the only apocynum used and that there can be some standard of activity. It may become a useful drug, but it cannot be depended on at present, and doubtful drugs should not be certified to in the revised Pharmacopeia.

BARII CHLORIDUM: BARIUM CHLORID

Description. — Barium chlorid occurs in colorless, translucent crystals which are very soluble in water and have a salty, bitter, and decidedly astringent taste.

Local Action.—The soluble salts of barium do not irritate the skin, but are decidedly irritant to mucous membranes and therefore will cause vomiting and purging in concentrated solutions.

Systemic Action.—Barium is one of the most poisonous of the alkaline earths. The salts are absorbed rather slowly from the stomach and intestine and after prolonged administration may be deposited and stored up in the bones. After absorption the chlorid of barium has a decided action on the circulatory system. It stimulates the cardiac muscle to more energetic contraction which becomes with poisonous doses a tetanic contraction, the heart stopping in systole. The blood-pressure is raised rapidly not only from the increased cardiac action, but principally from the contraction of the muscular coats of the arterioles. This action is largely local as dilatation of these vessels does not occur after the spinal cord is cut. The heart is slowed in its action, but whether this slowing is entirely due to the increased resistance offered by the contracted blood-vessels, or due also to stimulation of the pneumogastric nerves has not been decided.

In mammals, absorption of poisonous doses of the barium salts will cause tonic and clonic spasms, showing that this metal is decidedly irritant to the spinal cord and medulla oblongata. In fatal poisoning there is paralysis of the central nervous system. The pupils are sometimes dilated by the action of large doses. Barium increases the contractile power of the muscles enormously, resembling the action in this respect of veratrin. There seems to be no special action on the glands of the body, except that it can produce salivation, like some other metals, and the bronchial secretion may be increased.

Barium chlorid is excreted both in the urine and into the intestines.

Action of a Therapeutic Dose or the Primary Physiologic Action.—An active dose of barium chlorid produces a slight slowing of the heart, an increase in the strength of the cardiac contractions, and a decided increase in the arterial tension. Other symptoms or signs of physiologic action would seem to tend toward the action of too large a dose.

Toxic Symptoms.—Unless the solution is very dilute there will be the symptoms of gastro-intestinal irritation and erosion, which means thirst, vomiting, purging, pain, cardiac stimulation, soon followed by more or less symptoms of shock, with convulsions and dilated pupils, the latter probably due to stimulation of the sympathetic nerve. Before death the bladder also becomes very irritable. The final demise might be by coma or by sudden stoppage of the heart in systole. As little as 0.15 gram (2½ grains) can cause death.

Treatment of Poisoning.—The chemical antidote is any soluble sulphate, as magnesium or sodium sulphate, in large dose, this forming barium sulphate which is practically insoluble. The other treatment would be that for any other gastro-intestinal irritant, and some drug to quiet nervous irritation, as bromids and chloral. Nitroglycerin or aconite might be good treatment to overcome contraction of the blood-vessels and the irritations of the cardiac muscle.

Therapy.—Clinicians differ largely in their opinion of the value of barium chlorid in cardiac debility, but a sufficient number of satisfactory cases have been reported to indicate that barium chlorid may be of value when there is weakness of the ventricles from valvular disease, and in acute dilatation. It has been used to aid the circulation and better the local condition in varicose veins. Its power to stimulate the smooth muscle fiber has caused it to be used in paresis of the intestines and in paralyzed conditions of the bladder. Barium chlorid sometimes slows the heart and improves the circulation in Graves' thyroid disease.

Contra-Indications.—In conditions of high blood-pressure, or atheroma, or nervous irritability, or where there was acute inflammation of the brain or spinal cord this drug would be contra-indicated.

Administration.—Barii chloridum is not official. The dose is about 0.02 gram (⅓ of a grain), best given in tablets or in capsules, after meals.

There is no sufficient reason for recognizing this salt in the revised Pharmacopeia.

REMARKS

It can almost be guaranteed that there will be no increase in the number of deaths from arterial, cardiac, renal, and hepatic disease if the above drugs (adonidin, convallaria, cactus grandiflorus, spartein, apocynum cannabinum, and barium chlorid) are not recognized in the revised Pharmacopeia.

1. They are all inferior to digitalis and strophanthus which they are said to, and in some instances do, mimic pharmacologically and therapeutically.

2. They are much more uncertain in their action than digitalis and strophanthus.

3. Of all drugs to be officialized, inferior cardiac drugs should be the last. It is a dangerous thing to give standard and standing to a heart tonic that is unworthy, or to give the prescriber a sense of false security as to the therapeutic usefulness of a drug by the backing of fifty picked men, and such backing is the physician's interpretation of the Pharmacopeia.

SATURDAY, APRIL 1, 1911

COMPRESSED-AIR ILLNESS AND ITS PREVENTION

In the evolution of industry, which more than anything else characterizes our present age, preventive medicine is assuming greater and greater importance; and in no special province is this truer than in the fields of engineering, where not only the problems of tropical sanitation, but the details of more ordinary undertakings, are being subjected to medical supervision. Embodied in a report to the governor of Illinois by a Commission on Occupational Diseases,[1] is a discussion by Bassoe of caisson disease, which well illustrates this phase of modern medicine. Although the occurrence of compressed-air disease has long been known, the increasing frequency of work that requires continued use of high air pressure makes this an important industrial disease, and Bassoe's report on its occurrence in Illinois, which includes a summary of our present knowledge, is well calculated to serve as a basis for its better control.

For a theoretical study of the peculiarities of caisson disease, we are chiefly indebted to work conducted under the auspices of the British admiralty by Boycott, Damant and Haldane,[2] who were able to demonstrate these practical points: first, that it is the nitrogen of atmospheric air alone that plays an important part in the production of the disease; second, that increased exposure to high pressure gives added risk up to about five hours for man, at which time saturation of the body with nitrogen is practically complete; third, that it is rare, if ever, that symptoms of caisson disease occur under an excess of pressure of 1.25 atmospheres, however long the exposure; fourth, that death is due nearly always either to pulmonary gas embolism, or to blockage of vessels in the spinal cord by gas. Since the excess gas in the tissues does injury solely by its sudden increase in volume on removal of pressure, and since the body can tolerate a sudden decrease in pressure of from 2.25 times normal to normal, they point out that it is safe to decompress from any stage whatever by successive reduction of one-half at a time, thus, by Boyle's law, keeping the volume of liberated gas within the limits of safety. This type of decompression they designate as the "stage" method, as contrasted to the more usual practice of a slow uniform rate of reduction.

That the adoption of such a precautionary measure would almost completely obviate danger in physically sound individuals is shown by the experience of the workers in the East River tunnel at New York, as reported by Japp.[3] Here it was found that by the use of stage decompression, associated with muscular exercise (walking), danger was practically eliminated for seasoned workers.

Such a record, where 330 men were employed for thirty-six days, stands in striking contrast to statistics gathered before the use of preventive steps. Thus, to cite a few American experiences only, there were 119 cases, with fourteen deaths, among 600 men employed on the St. Louis bridge, and on the construction of the first Hudson tunnel there were, before the introduction of a "medical lock," twelve deaths among the forty-five or fifty men employed. Careful search appears to show that the disease is much more frequent than imagined, as is shown by Bassoe's ability to collect 161 previously unreported cases in Illinois, where, aside from the St. Louis bridge cases just noted, he was able to find previous references to only three cases.

In regard to the necessity for special legislation to maintain proper safeguards, it has been urged that the common law principle of holding contractors and corporations responsible for preventable injury to employees should suffice. But that this does not do so, at present at least, is decisively shown by the frequency with which the disease occurs.

SEX INSTRUCTION IN THE SCHOOLS

At the recent annual conference of the American School Hygiene Association a paper was read by Dr. Charles W. Eliot, ex-president of Harvard University, on school instruction in hygiene.[1] Dr. Eliot devotes considerable space to the problem of education in sex matters, coming to the conclusion that under present conditions it is desirable that such instruction should be given in the schools. The objection that the subject is an unclean one and unsuitable for such public discussion he answers by pointing to the disastrous results that have obtained in the past from allowing this objection to govern our policy. Another objection is that the subject is such a sacred one that it can properly be discussed with children by their parents only. To this Dr. Eliot replies that, while the instruction of children in this subject by parents is most desirable when possible, a great majority of parents possess neither the necessary knowledge nor the power of expression to instruct their children properly on this subject.

The general outline for such a scheme of teaching consists of a prolonged course of natural history, beginning early with botany and progressing to an elementary consideration of zoology, using every possible means of illustration, both indoors and out. Children should be thoroughly acquainted through such means with the principles of the various modes of transmitting life "before any sex emotions begin to stir in them." Later the course should include physiology and should teach something of the causes of disease, by no means omitting, though not unduly emphasizing, the venereal affections. One of the dangers to be avoided in such instruction, as we have remarked before,[2] is the placing of disproportionate stress on the negative side of the subject.

---

[1] An *editorial* on other diseases mentioned in this report appeared in THE JOURNAL, March 25.

[2] Jour. of Hyg., 1908, viii, 342.

[3] Tr. Am. Soc. Civil Engineers, 1909, lxv, 1.

[1] Survey, Feb 11, 1911, p. 803.

The plan outlined is not a new one, but the fact that it emanates from so distinguished an authority in educational matters entitles it to fresh consideration. No one competent to judge the question will attempt to refute Dr. Eliot's two fundamental propositions: the evils which result from the "world-old conspiracy of silence," and the unfitness—at least, the unreadiness—of a large proportion of parents to instruct their children in sex hygiene. To admit these two facts, however, will scarcely be, for many perplexed educators, to see the way clear to the introduction of the subject in the public schools. From the published abstract of Dr. Eliot's paper, we are unable to judge of the consideration which he gave to the not inconsiderable amount of pioneer work which must first be done. It may be that the practical difficulties which loom large to those working at the bottom of the educational structure dwindle in perspective when viewed from the top.

Parents who are unfit to give instruction to their children cannot therefore be regarded as negligible factors in the educational scheme. It would be rash to attempt to instruct children in the fundamental facts of life without first soberly and tactfully educating their parents, carefully avoiding undue shock to prejudice and unnecessary affront to custom. No one engaged in this task can afford to forget that at present the unvarying decent concealment or avoidance of certain subjects almost usurps the place of morality in the esteem of many people, both the overdainty and ultrarefined on the one hand and the densely ignorant on the other. It will not do for the school to disturb in the minds of children ideals still respected in their homes. The conflict of authority that is sure to result will be detrimental to the influence of both school and home; but the school will suffer most, and deservedly.

Here the cooperation of the family physician will be of the greatest value. The physician may not often have the opportunity of instructing children and young people; indeed, many physicians have no special aptitude for the task. The opportunity of enlightening the older members of a family, however, must often come to every general practitioner, and he has only to use it judiciously to accomplish much good, since on these matters advice which would not be tolerated from a layman will generally be received with respect from a physician.

The need for more widely diffused knowledge of this nature is so great that the experiment of introducing the subject in the public schools seems to be urgently demanded, though there is no need to forget that it is an experiment. It would be foolish to regard the difficulties in the way as insuperable; it would be equally unwise to minimize them. While so much of method remains to be worked out, it would not be prudent to demand work along this line from any educators except those best qualified by wisdom, experience and the confidence of the communities in which they labor. We hope that some of these may before long produce results that will justify others in following their lead.

THE LOCKED DOOR

Once more the drowsy conscience of the country has been shocked broad awake—for a moment—by horror. One hundred and forty-one human beings, most of them women and young girls, have met a frightful death through the indifference or greed—or both—which controlled their fates. What gives added poignancy to the ghastly tale is the fact that we knew it all before. The "fireproof building," packed with tinder and human fuel—the inadequate fire-escapes—the locked doors, piled high with dead—every detail of the tragedy has been rehearsed over and over again; the stage is set even now in hundreds of places for its repetition. It is said that the Asch building, where this fire broke out, is only one out of many in Greater New York where such a catastrophe might have occurred; that New York is not unique in this respect, scores of cities in this country can bear shamed and sorrowing witness.

It is not worth while to anticipate the dreary and well-nigh futile task of the authorities in "fixing the blame." We cannot, however, evade the task of pointing out at least one of the lessons which by now ought to be writ large in the memory of every conscientious citizen—the lesson of the locked door. It will be remembered, by the way, that the Triangle Shirtwaist Company (the establishment affected by the recent fire) was the concern in which the New York shirtwaist-makers' strike began, something over a year ago. This holocaust writes a grim commentary on the demands of the workers for better living conditions; the locked door fitly symbolizes the attitude of employers of this class.

To the public's demands to know whether the health and welfare of employees are endangered by lack of light and air, exposure to infection, excessive hours of work, unprotected and dangerous machinery, wages insufficient for a proper standard of living, such employers have but one answer, however they may phrase it: "This is a private business." It is the slam of a door and the turn of a key; it means that, in the estimation of the proprietors, a man's business is his castle. Laws regulating the hygienic conditions of industry are, from this point of view, an unjustifiable interference with private enterprise.

---

[2] Sex and the Instruction of the Young, The Journal A. M. A., March 11, 1911, p. 746.

Our modern industrial organization permits a "captain of industry" to hold the lives of hundreds and thousands in the hollow of a callous and unsteady hand. Even barring out such spectacular calamities as the recent fire in the Triangle Shirtwaist Company's premises, the moral and physical well-being—the very existence—of those who earn their bread by their day's labor is more affected by the rules and conditions established by their employers than it is by the whole machinery of civil government outside. Can we permit such an *imperium in imperio,* ruled for private profit, to be carried on behind locked doors, figurative or literal?

In the present instance, doubtless, some little good will be accomplished if the guilty individuals receive punishment a tithe as prompt and exemplary as that meted out to the irresponsible wastrel who stabs his fellow in a drunken brawl; but this is scarcely to be expected. What is most to be desired is that we shall all realize our share in the joint responsibility for such disasters and the conditions that lead up to them. He who looks on unprotesting is guilty in that degree.

THE FETISH OF PRECEDENT

Inasmuch as the question of employers' liability for injury to workmen is in certain of its aspects a problem of preventive medicine, it is of interest to note the recent decision of a New York court declaring unconstitutional a law of that state providing for the compensation of workmen injured in the line of their duty.

The main feature of the act was that it required employers of labor in certain dangerous occupations, such as bridge-building, operation of elevators, work on scaffolds, work on electric wires, working with explosives, on railroads, tunnels, and work carried on under compressed air, to compensate their employees for any injury occurring during the course of the work, whether or not such injury occurred through the negligence of the workmen. The considerations which justify disregard of the employee's negligence are, first, the difficulty—the practical impossibility—of holding the employer to any responsibility if the employee must first be cleared of all blame, and, second, the fact that, in the main, the negligence of the employee is within the control of the employer. To the working man dependent on his daily labor, the more or less remote chance of losing his life does not for a moment balance the immediate certainty of losing his job. The most cruel injustice of the doctrine of contributory negligence lies in the opportunity it gives to the employer, while tacitly requiring the worker to take a risk, to evade all responsibility for its consequences because it is impossible to prove that the employee did not take this risk on his own initiative. As soon as it is made unprofitable to employ working men who are negligent of their own safety, such negligence will cease to be an appreciable factor in industrial accidents.

The New York law was modeled on the British workmen's compensation act of 1897, which has since been extended to cover every kind of occupational injury. This law has been upheld by the courts of Great Britain and has been found to work to the satisfaction of both employers and employees, in that country.

The New York court admits the strength of the economic and sociologic arguments adduced in support of the statute, but holds that "under our form of government courts must regard all economic, philosophic and moral theories, however attractive and desirable they may be, as subordinate to the primary question whether they can be molded into statutes without infringing on *the letter or spirit of our written constitutions.*" The court points out that the law abrogates the "fellow servant" doctrine, and also the rule in regard to "contributory negligence," two venerated precedents that were eagerly seized on by the courts of this country almost as soon as they were enunciated, and have been worshipped and invoked ever since. It is admitted, indeed, that the legislature has the right to abolish both of them. The New York court, however, sweeps aside British precedent, sound common sense, the admitted power and expressed will of the legislature, and falls back on that other hallowed fetish frequently invoked by corporations and trusts when their special privileges and profits are threatened, the deprivation of property without due process of law, etc. No matter, therefore, under what stress of necessity a man engages in a hazardous employment, wherein often even the most elementary provisions for safety are disregarded by the employer—no matter how much it may cost the general public to care for an injured employee and his dependents—the court decides that the sacred right of property must not be invaded. As for the public, if it ever had any rights these, evidently, have long since vanished, swallowed up in the tortuous mazes of legal precedent.

On the very heels of this decision comes an instance in the same state of the need and justice of such a law. The terrible fire in a factory in New York City wherein over a hundred lives were lost, and many persons injured, illustrates how the public pays for the indifference of employers to the safety of their people. In defiance of state laws and city ordinances the proprietors of this factory and the owner of the building had neglected to provide adequate exits or means of escape from their building, although it is asserted that the stock and machinery were heavily insured against fire loss. This fire has already cost the city of New York thousands of dollars for the care of the dead and injured, and the ultimate expense to the public, taking into account not only the killed and maimed, but those dependent on them, no reckoning can compute.

It is only too plain that, until it is made unprofitable for employers to despoil their laborers of life and strength and to throw the human refuse on the scrap-heap, to be disposed of at public expense, the inhuman and senseless waste will go on. The blood of the worker is part of the cost of production; but private industry will not pay that cost if it can be shifted to the general public.

To those who look ahead, the decision of the New York court is matter for regret because, but not solely because, it perpetuates an ancient wrong. It shows a failure of the courts to understand the age in which they are living. "What we know as men," said the Illinois Supreme Court not long ago, "we cannot profess to be ignorant of as judges." We commend this fine saying to the consideration of courts elsewhere. Too often the courts have seemed entirely to ignore, either as men or as judges, facts which are patent to the man on the street; too often they have seemed to seek precedents to justify setting at naught the will of the people, expressed through the legislatures. It is not radicals, but conservatives, who have most reason to regret this, for it presages a day of reckoning in which precedents shall go for very little.

Current Comment

HYGIENE IN THE ARMY ON THE BORDER

We recently commented on the mobilization of a considerable military force in Texas for maneuver purposes, and suggested that this would give an opportunity to the Medical Department of the Army to show what progress had been made since 1898 in army sanitation and hygiene. Though the facts were not then at hand, it was suggested that undoubtedly vast improvement had been made in this respect. A correspondent in a New York daily paper has raised the same question and inquired what was being done in sanitary matters to prevent a repetition of the experiences of the army in 1898. Under the authority of the War Department, a reply was made to this inquiry, setting forth what had been done in preparing for the maneuvers in Texas. It was stated that at the time of issuing the order for the mobilization of the army the Army Medical School was ready to supply, for inoculating the troops in the field, an antityphoid serum which had been previously tested by 20,000 inoculations in the regular army, and had proved its efficiency. The inoculations are now being applied to the entire force in the field. It is asserted by the War Department that this is a feat of preventive medicine which for magnitude and promptness of execution is unique in military history. Among other measures, a carefully tested system of the disposal of wastes has been put into operation, which will prevent camp epidemics and defeat the dangerous activities of the common fly. Sanitary squads of hospital corps men, under competent medical supervision, have been provided to secure cleanliness of the camps. Trained sanitary inspectors and field laboratories are now provided and the sanitary personnel, while somewhat short in numbers, is expected to be filled up in case of necessity from the Medica Reserve Corps and by the enlistment of Hospital Corps volunteers. The plans for temporary hospitals are drawn and specifications are printed and ready for the builder The reorganized Red Cross, with its enrolled trained nurses, also stands behind the reorganized medical service. As illustrating the preparedness of the department for service, it is said that the hospital equipment and medical supplies for the volunteered force left the field depots in Washington and St. Louis while the troops were being entrained and arrived in San Antonio at practically the same time as the troops. It is satisfactory to realize that ten times the force could have been supplied and equipped with equal promptness. Although the Army has been in the past, and even now is, more or less handicapped by the reluctance of Congress to provide for a sufficient medical personnel and equipment yet present conditions indicate that the Medical Department has evolved an efficient organization and is prepared to cope with actual war conditions, according to modern ideas, in a highly efficient manner. The experience in Texas will no doubt prove that our medical forces and organization are equal to those of any other nation.

MAIL-ORDER MEDICAL SPECIALISTS

In one of his articles on quackery, Mr. Samuel Hopkins Adams likened the mail-order medical faker to a man who would offer to mend chimneys by mail. The comparison is a homely one, but apt. Diagnosing and prescribing by mail, as carried on by the typical medical mail-order house, is a fraud *per se*. As a corollary of this axiom, it follows that any person who offers, for monetary or other consideration, to prescribe or treat on the mail-order plan is a swindler and a cheat. Yet, there are in this country hundreds, possibly thousands, of concerns that are doing a flourishing business in this line of work. A few of these The Journal has exposed and a few more it expects to expose. But, in the very nature of the case, those which we are able to investigate are but a drop in the bucket of quackery. In the "Propaganda for Reform" department of this issue there is an article dealing with a mail-order medical fake calling itself the Dr. Bertha C. Day Company. Physicians will find very little in this article with which they are not already familiar, but they will find a great deal with which their patients are unfamiliar. Few physicians realize the degree of ignorance that exists among the public generally, regarding mail-order medical quacks Because the fraud that characterizes these concerns is so perfectly evident to the physician, he is unable to comprehend how it is possible for presumably intelligent laymen to be misled by the specious promises of the mail-order quack. The fortunes that have been, and are being, made by the unscrupulous individuals who conduct such concerns is in itself sufficient to prove that the public is still easily fooled. The purpose of articles, such as that which appears in this issue, is to enable physicians to place in the hands of their patients such information as will convince the most gullible of the fraud that is inherent to quackery. The Bertha C. Day article, together with a number of similar articles, will be reprinted in pamphlet form and sold at a merely nominal price. We know of few things on which the public needs enlightenment more than the subjects of quackery and the nostrum evil; we know of no better way of bringing about this enlightenment than by the wide dissemination of articles such as these. It is to be hoped that physicians will realize their responsibilities and opportunities in this matter.

THE RISKS THAT PHYSICIANS RUN

During the past week three deaths have been reported of resident physicians in hospitals, from diseases contracted from patients whom they were attending. Two of these deaths were from cerebrospinal meningitis brought to New York City by passengers from Greece; the third—in Chicago—was from scarlet fever. The records of the dead in the medical profession are full of similar instances, not only in cases of young interns, but of busy family practitioners, who have faced death fearlessly in their professional work and have gone to death as fearlessly. In exceptional instances, as in those just mentioned, the work which brought such men to their death has been done in the public eye, and they have consequently received the martyr's meed of lament and eulogy. Seldom or never has the spectacular element been a motive for the deed. Although it is impossible for the world to pay fitting individual tribute to all such heroes, we may regard the honors paid to a few as given to representatives of a heroic class. All have done their duty and deserve the same honors that are paid to soldiers who die in line of duty.

A SAD SEQUEL TO CONSCIENTIOUS WORK

In contrast to the situation referred to above, the physician may find that his duty brings him into direct conflict with the wishes of the public. He may be called on to exert considerable strength of character in order not to fail in any respect in his duty. Especially is this so when not only his own pleasure and comfort are concerned, but the happiness and even the lives of his family. Such a case was recently described[1] in these columns. The report of a case of typhoid by Dr. Franz, an Austrian district physician, caused a change of plans by the authorities so that military maneuvers were not held, and thus the villagers were deprived of pleasure and profit. A boycott and persecution followed. The physician could not obtain a nurse for his wife during her confinement. No one in the village would sell him food; he had to get meat and vegetables by mail.[2] His windows were broken about once a week. The ordeal was so severe and the resultant anxieties so wearing as ultimately to bring on the physician's death. The government has taken the matter in hand most actively and will severely punish the guilty persons and enforce the payment of money damages to the family of the dead physician. As detailed by our Vienna correspondent, the case is an extreme one, but it merely illustrates the position in which a physician may be placed when the demands of public health run counter to the temporary desires of the community. The process of educating the public all over our own country on the subject of public health—what it means and what it requires—is gradually going on. It requires time; it requires patience; it requires far-sight, but no one can deny that advance is being made. The period on which we have entered has been called the "Public Health Era" and physicians of to-day are most fortunate in the opportunities they have in not only witnessing it, but in being active factors.

PRELIMINARY EDUCATION SHOULD ACTUALLY BE PRELIMINARY

At the recent meeting of the Association of American Medical Colleges an important step in advance was taken in regard to its requirement of preliminary education. An amendment to the constitution was adopted providing that after Jan. 1, 1912, all colleges holding membership in the association shall require of every student admitted at least a completed four-year high-school course or its equivalent, no "conditions" to be permitted. Heretofore, students might be admitted conditioned in as many as six points or three units of high-school work. Since the entire four-year high-school course consists of only thirty points, or fifteen units, therefore, the constitution permitted the colleges to accept students conditioned in 80 per cent. of a year's work in entrance subjects; which, according to another clause of the constitution, were to be removed before the student began work "in the second year of his medical course." Not only was a student thus conditioned allowed to begin the difficult study of medicine without the necessary preliminary education, but he was given the Herculean task of completing nearly two years of work in one. The instance is exceedingly rare in which a student can honestly and satisfactorily make up three units of entrance conditions and at the same time obtain satisfactory grades in the first-year studies of the modern medical course, and the better colleges, recognizing that fact, have refused to admit students so heavily conditioned. In only too many of the institutions, however, such conditions are never removed or else easy makeshift methods are provided, the whole arrangement being used by many colleges as a pretense of living up to a fixed standard. By such institutions, any fixed requirement will be stretched to the farthest limit permitted by the association. Any entrance condition, the removal of which is actually required by the college, is an added handicap to the student whose burdens in the modern medical course are already becoming too heavy. This is the chief reason why a better preliminary education is necessary. To be of any practical value, however, such education must be completed before the student is admitted to the medical college. In other words, preliminary education should *be* preliminary. The amendment adopted by the association is therefore an important step in advance.

---

[1] THE JOURNAL A. M. A., Feb. 4, 1911, p. 362.

[2] Note the convenience of the parcels post. There is one bright side to this picture. The doctor could get meat and vegetables by mail! In the United States—thanks to the express companies and their control of our legislative bodies—the parcels post is too limited in its possibilities; but that is another story.

PROPORTION OF PHYSICIANS TO POPULATION IN THE UNITED STATES

At a series of conferences on medical education and medical legislation, recently held in Chicago, someone made the statement that the number of physicians legally licensed to practice medicine in the United States was 120,000, making approximately one physician for every 800 people. This statement has been the basis of various newspaper comments all over the country, and so the error will be passed on till someone guesses some other number and makes the guess public. The number of physicians in the United States is variously given by various individuals—sometimes it is as low as 100,000, at others as high as 160,000. There are, at present, between 139,000 and 140,000 individuals, practically 140,000, who are licensed practicing physicians in the United States, or approximately one physician for every 650 people. But it should be remembered by those who make comments on this subject that the above figures do not include the "vitapaths," "naturopaths," "osteopaths," "panpaths," "chiropractics," "mechanotherapists," Eddyites, "magnetic healers," etc., who, whether they be said to "practice medicine" or not, are making diagnoses and are professing to treat human ailments. The number of these in practice we would not dare to estimate. Especially must the followers of these cults be considered when we are comparing the proportion of physicians to population in this country with that of some other countries where these cults do not exist.

PROGRESSIVE PREVENTION OF EPIDEMICS

The efficient handling of the cases of meningitis coming to New York from Greece within the past two or three weeks speaks well for the quarantine service at that port. All cases seem to have been promptly recognized and isolated, preventing the spread of the disease. The intensive study of this disease, which culminated in the Flexner serum, has given such an accurate knowledge of this infection that, except in communities poorly equipped with health and quarantine organizations, where the disease may gain a substantial foothold, danger of serious or prolonged epidemics is very nearly *nil.* Almost or quite as good results are assured in handling the still more deadly infections, cholera and plague; and poliomyelitis will no doubt soon be equally controllable through advance in scientific knowledge. It is a source of extreme gratification that meningitis and the other devastating infections have so far yielded to the direct attacks of science.

Medical News

CALIFORNIA

Personal.—Dr. Daniel B. Northrup, health officer of San Diego County, is reported to be ill with septicemia.——Dr. Edward R. Wagner, San Jose, has returned after six months in Europe.

Segregation Experiment.—The hospital which is to be operated in connection with the proposed plan for the segregation of prostitutes in San Francisco, opened March 21, at 684 Commercial Street, under the supervision of Dr. William F. McNutt, health officer of the city.

San Joaquin Physicians Meet.—The thirty-first semiannual meeting of the San Joaquin Valley Medical Society was held in Fresno, March 14. The following officers were elected: president, Dr. Walter E. Lilley, Merced; vice-presidents, Drs. George H. Aiken, Fresno, and Charles O. Mitchell, Laton.

Pasadena Entertainment Fund.—At a meeting of the executive committee of the Los Angeles Convention League it was announced that the physicians of Pasadena had raised a fund of $3,000 for the entertainment of delegates to the American Medical Association meeting, and that Adolphus Busch would give a barbecue on the grounds of his Pasadena home to the visitors at a cost of $10,000.

IDAHO

Personal.—Dr. Francis H. Poole, Pocatello, has been appointed superintendent of the Idaho State Insane Asylum, Blackfoot, vice Dr. Clayton A. Hoover, who will locate for practice in Pocatello.——Dr. Frank L. Barrows, Moscow, has started for Europe, via Philadelphia, where he will spend three months.——The Idaho supreme court is said to have decided that the State Board of Medical Examiners must issue a license to practice medicine to Dr. Emanuel Vadney, who has practiced for thirteen years in Morrow.

ILLINOIS

Personal.—Dr. Frank H. Jenks, assistant superintendent of the Elgin State Hospital since 1897, has resigned. Dr. Jenks has purchased the Ransom Sanitarium at Rockford and will assume charge May 1.——Dr. Lester C. Diddy, Oswego, who has been seriously ill at St. Charles Hospital, is improving. ——Dr. Clarence T. Roome has been appointed medical inspector of schools of Evanston.——Dr. Benjamin Gleeson and family, Danville, sailed for Europe, March 31.

Legislative Progress.—The osteopathic bill, House Bill No. 380, has been killed in judiciary committee of the house; the optometry bill, Senate Bill No. 140, is still in senate committee on sanitary-district affairs; and optometry bill, House Bill No. 121, is still in house committee on judiciary. These two bills, which are practically identical, should be defeated, as their enactment would be detrimental to the interest of the lives and health of the people of Illinois. For this reason they are opposed by the State Board of Health.

State Board Convictions in Chicago.—The following convictions for violation of the Medical Practice Act have been reported by the State Board of Health: V. Potenza, an old offender, fined $200 and costs.——Mrs. A. Kohler, a fortune teller who gave medicine, $100 and costs.——W. E. Krause, a "chiropractor" who claims to be a physical culturist, $100. ——Mrs. Herbert Gray, who exploits the "Novita Remedies," $100 and costs.——Rosina Bisesi, a midwife, $100 and costs, and C. J. Ostberg, a "chiropractor," convicted. McCormick, of the so-called McCormick Medical College, and a "Dr. Worth" testified. McCormick was asked whether his school was recognized by the State Board of Health. He said that it was not, nor did he ever want any recognition. Worth represented himself as an osteopathic physician who said he did not have a license from the State Board of Health nor did he care anything for the board. Ostberg appears to have been misled by McCormick.

Chicago

Personal.—Dr. Samuel J. Walker, who was operated on for appendicitis, March 23, is reported to be making satisfactory progress toward recovery.——Dr. H. Wernicke Gentles left Chicago, March 27, for a visit to Scotland.

Woman's Club to Manage Hospital.—The difficulties which have surrounded the management of Mary Thompson Hospital are to be shouldered by a committee of eight members of the Chicago Woman's Club, to be appointed by the president. These women are to act on the board of the hospital and will officially represent the active interest which the club is taking in the institution.

Additional Gift to Medical School.—At a meeting of the trustees of Northwestern University, March 23, it was announced that James H. Patten had added $50,000 to his gift of $200,000 for the establishment of a department of research on infectious diseases, at the medical department of the university. Everything will be ready in the fall for the opening of the laboratory and the start of research work.

To Celebrate Foundation Day.—Northwestern University will celebrate the twenty-fifth anniversary of the founding of the School of Pharmacy, April 12 and 13. In conjunction with the celebration, the faculty, alumni and students of the school have planned special exercises in honor of the dean, Oscar Oldberg, who will have completed twenty-five years of service at that time, and expects to retire from active duty because of ill health.

INDIANA

Medical Students in Accident.—Harry H. McCoy and Claude Niedhamer, students of the Indiana University College of Medicine, were struck by an interurban car near Indianapolis, March 24. McCoy was killed and Niedhamer was seriously injured.

Antituberculosis Society Organized.—The White Plague Warfare Recruits, with headquarters at Frankfort, has been incorporated. The organization has no capital stock, but its object is to fight tuberculosis, and it plans to buy property, build fresh-air camps and conduct warfare against white plague.

Personal.—Dr. George J. Studer, who has been seriously ill at the Lutheran Hospital, Fort Wayne, is reported to be considerably improved.——Dr. Eduard J. McOscar, Fort Wayne, has returned from a five weeks' trip to Central America and Panama.——Dr. and Mrs. George W. Combs, Indianapolis, left for Europe, March 23.

IOWA

Personal.—Dr. David T. Martin, Pomeroy, who was seriously injured in a runaway accident, is a patient in Mercy Hospital, Fort Dodge.——Dr. George P. Hanawalt, Des Moines, who has been seriously ill with asthma, is reported to be convalescent.——Dr. John C. Lewis, Ridgeway, is said to have sold his practice and is about to retire.——Dr. Gershom H. Hill has been elected president of the Associated Charities of Des Moines.

Faculty Changes.—Rudolph Flebbe, Ph.D., a graduate of pharmacy of the University of Leipsic, and later assistant in the government agricultural research station, has been secured as head of the clinical laboratory, of the pathologic department of Drake University Medical College, with the title of instructor in pathology. His time will be devoted almost entirely to individual research and the supervision of research work of special workers in his laboratory.——Dr. Hubertus J. M. Hoeve, for several years instructor in anatomy in the Medical Department of Drake University, will, it is said, sever his connection with that institution at the end of the winter semester.

MARYLAND

Portrait Presented.—The friends of Dr. Charles M. Ellis, Elkton, have had painted a portrait of him, which will be presented to the Medical and Chirurgical Faculty of Maryland, of which he was once president.

New Hospital.—The trustees of Havre-de-Grace Hospital take possession of the Baker property, April 1. Articles of incorporation have been filed and the first instalment of the purchase price is ready. Work on the building will soon commence.

Baltimore

Must Give Up Private Practice.—It is announced that the members of the medical and surgical staff of Johns Hopkins Hospital will be required to give up private practice and devote themselves exclusively to the work of the hospital.

Personal.—Dr. Ernest H. Gaither sailed for Germany, March 25.——Dr. James M. H. Rowland is suffering from an infection of the right hand.——It is announced that Dr. Alexius W. McGlannan has resigned as chief surgeon of the Maryland National Guard.

Department of School Hygiene.—Baltimore is to have a department of school hygiene in connection with the Department of Health. The plan originated with Dr. John M. T. Finney. Most of the diseases and mental weaknesses found among school children are believed to be due to unsanitary conditions in the schools.

Pasteur Institute Report.—During the last year 123 persons were treated at the Pasteur Institute, 20 in wards, and 103 at their homes. There were 53 persons bitten by animals demonstrated to be rabid by cerebral inoculation of rabbits. Wounds were inflicted by dogs in 113 cases, cats in 7, horses in 2 and by a calf in 1. One death occurred.

MASSACHUSETTS

Awarded Medal for Bravery.—Dr. Francis E. Park, Stoneham, has been awarded a medal for bravery by the Massachusetts Humane Society for the rescue of a laborer in a sewer overcome by fumes from a tannery.

College Building Enlarged.—Tufts College Medical School, Boston, has enlarged and remodeled its college building at an expense of approximately $50,000. A fourth floor has been added to the entire building and several important changes have been made on the other floors.

Personal.—Dr. William M. Gay has been appointed port physician of Boston.——Dr. Francis X. Crawford succeeds Dr Gay as assistant port physician.——Dr. Bertha F. C. Frommell, Fairhaven, has been elected a member of the board o health of New Bedford.——Dr. Charles A. Reese has bee elected a member of the board of health of Wellesley Hills.——Dr. Paul Carson, formerly port physician of Boston, has bee transferred to the division of school hygiene.——Dr. Simeo B. Wolbach, assistant professor of bacteriology in Harvar Medical School, has started for West Africa, to study sleeping sickness.——Dr. Samuel H. Durgin has been reappointed chairman of the Boston Board of Health.——Dr. Richard Collin has been appointed a member of the Waltham Board of Health ——Dr. Frederick F. Andrews has been reelected a member o the Revere Board of Health.

MINNESOTA

State Health Department Bulletin.—The health departmen announces that it will issue in a few days, the first numbe of a monthly bulletin in pamphlet form, which will contain al statistics pertaining to the department.

A New Antituberculosis Association.—An antituberculosi association has been organized in Crookston, with Dr. Thoma Spence as a member of the board of directors, and Dr. Halvo Holte as chairman of the finance committee.

Physicians' Building.—Plans have been made for the erection on the Stewart Homestead, Hennepin Avenue and Fourt Street, Minneapolis, of a ten-story reenforced concrete building for physicians and dentists, to cost about $700,000.

Unlicensed Doctor Fined.—Henry Wuerzinger, Minneapolis is said to have been found guilty, March 2, of practicing medicine without a license and fined $50.. This action is said to b the result of internal strife in the Minnesota Association o Naturopaths, which made the complaint, and of which th defendant formerly was president.

Personal.—Dr. Paul B. Cook has been appointed first assistant to the commissioner of health of St. Paul, vice Dr. John M Armstrong.——Dr. Gustav A. Rentz, formerly health commissioner of St. Paul, leaves this month for Europe.——Dr. Gusta A. Magnusson, Aitkin, has been appointed instructor in bacteriology and pathology at the State University.

Physicians' Wives Meet.—The Woman's Auxiliary of Hennepin County Medical Association held its annual meeting i Minneapolis, March 13, and elected the following officers president, Mrs. William J. Byrnes; vice-presidents, Mrs. Charle A. Donaldson and Mrs. Thomas F. Quinby; recording secretary Mrs. J. Frank Corbett; corresponding secretary, Mrs. Ernes Z. Wanous, and treasurer, Mrs. Charles H. Hunter, all o Minneapolis.

Election.—At the annual meeting of Washington Count Medical Society, held in Stillwater, March 14, the followin officers were elected: president, Dr. Edgar O'B. Freligh, Stillwater; vice-presidents, Drs. James Haines, Stillwater, an Frederick A. Stevens, Lake Elmo; secretary-treasurer, D Wade R. Humphrey, Stillwater; censor, Dr. Burton J. Merril Stillwater, and delegate to the state association, Dr. Ernes E. Wells, Stillwater.

NEW YORK

Eyeglasses for Pupils.—Assemblyman Levy has introduce a measure which would require the Board of Education of Ne York City to furnish eyeglasses or spectacles to pupils in th public schools. This it is estimated would require the Boar of Estimate and Apportionment to appropriate $15,000 annually for this purpose.

The Insane.—There are now in this state 32,657 insane persons in hospitals, or about 1 to every 200 of the adult population. In 1890 the number of insane in hospitals and almshouses in this state was 16,006; this shows an increase o 104 per cent. The cost of caring for insane persons in th state hospitals last year was $5,659,942.76. The average cos for additional buildings for the insane would be about $1,000,000 if all were properly housed. During the past ten yea the state has spent for the care of the insane $54,018,36 About one-sixth of the total expenditure of the state is for th insane. It equals an annual tax of 70 cents on every ma woman and child in the state.

New York City

Increased Capacity at Beth Israel Hospital.—By the opening of a new ward, at a cost of over $10,000, the capacity of this institution has been increased to 140.

Personal.—The board of trustees of Bellevue and Allied Hospitals has appointed Dr. George O'Hanlon general medical superintendent, vice Dr. Winford H. Smith.

Hospital May Sell Buildings.—The directors of St. Andrew's Convalescent Hospital have received permission to sell the buildings of that institution for $27,000. It is the intention of the officials to move to new buildings on East Seventeenth Street.

Give Fund for Training School.—Mr. and Mrs. William Church Osborn, New York City, have presented a building costing $250,000 to be used as a club home and registry for nurses, the building to be known as Osborn Hall in memory of the late Mrs. William H. Osborn, to the Bellevue Training School for Nurses.

New Dispensary in Brooklyn.—The New Utrecht Aid Society has been formed with the object of opening a dispensary for the poor in the Parkville, Kensington, Windsor Terrace, and Borough Park sections of Brooklyn. The dispensary will be non-sectarian. The staff includes Drs. H. M. Calvin, John J. Masterson, M. B. Gordon, O. C. Stackhouse, J. J. Rosenthal, Edmund G. Silverman and Morgan T. McSheehy.

Health Bulletins.—The latest bulletins of the Department of Health of New York City urge parents to have children promptly vaccinated; advise parents who intend obtaining employment certificates for their children to secure the requisite evidence of age in the shape of birth certificate as early as possible; and decry the danger of the spread of cerebrospinal meningitis in the city, and call attention to the methods pursued by the board of health in guarding against a possible invasion of this disease.

Reduction of Infant Mortality.—The Committee on the Reduction of Infant Mortality of the New York Milk Commission is endeavoring to raise $200,000 to establish sixty milk depots; nearly $40,000 has already been raised. These depots will be conducted along the lines of those of the department of health. The committee states that there are born annually 65,000 babies in Manhattan; of these 12,000 need the aid of milk depots, 4,000 already receive it, and the remaining 8,000 the committee proposes to save. There are probably 16,000 poor babies in Manhattan under 1 year old who succumb to disease every year; probably half of this number could be saved with proper care and nourishment, such as could be given with the aid of milk depots.

The Need of Medical Missionaries.—On March 11, a mass meeting of medical students, hospital interns, and other practitioners was held at the Academy of Medicine to lay before the medical profession the demand for modern practitioners in unchristianized and uncivilized countries. Dr. William M. Polk, president of the academy, was in the chair, and in his introductory remarks, spoke on "The Medical Pioneer." He then introduced Sir Wilfred T. Grenfell of Labrador, who made an earnest appeal for men to devote their lives to the practice of medicine in foreign lands. He then showed by lantern slides the development of his own work in Labrador and Newfoundland. There were about 400 medical students and physicians at the meeting, which was promoted and held under the auspices of the Student's Club, the Intercollegiate Branch of the Young Men's Christian Association of New York City. There are already fifteen students in the medical schools in New York City who plan to go as medical missionaries to foreign lands.

PENNSYLVANIA

Clinical Society Election.—The annual meeting of North Penn Clinical Society was held in Sellarsville, March 15. Dr. James I. Cawley, Springtown, was elected president; Dr. J. Warren Bauman, Lansdale, vice-president; Dr. Walter H. Brown, Richlandtown, secretary, and Dr. John J. Ott, Pleasant Valley, treasurer.

Woman's Medical College.—A modern well-equipped clinical amphitheater has been erected recently for the Woman's Medical College of Pennsylvania at a cost of about $22,500, and is now in use. The building includes a complete sterilizing plant, anesthetizing and recovery rooms, dressing rooms for surgeons and assistants, and waiting rooms for patients. ——Beginning with the session of 1911 and 1912, entrance conditions at the college will be reduced from six to four points. Inorganic chemistry will not be accepted as an entrance condition but will be required in every case. This subdivision of chemistry will no longer be part of the work of the first year.

Personal.—Dr. Samuel G. Dixon, Commissioner of the State Department of Health, has appointed Dr. T. Ben Johnson, of Towanda, to succeed the late Dr. Skiles M. Woodburn as county medical inspector of Bradford County and chief of the state department of health tuberculosis dispensary in Towanda.——Dr. John A. Bouse, special state medical inspector, is dangerously ill at his home in Harrisburg, with valvular heart disease. Dr. Bouse had charge of the state health's department tuberculosis exhibition and superintended its presentation in the various cities throughout the state.——Dr. Colley Johnson Miller, Brownville, is seriously ill in St. Francis' Hospital, Pittsburg, as the result of an attempt at suicide, made March 20, while he was mentally irresponsible.——Dr. John B. Carrell, Hatsboro, sailed for Europe, March 23.——Dr. Cyrus L. Stevens, Athens, has been elected secretary of the Bradford County Medical Society, vice Dr. Skiles M. Woodburn, Towanda, deceased.

Philadelphia

President Guest of Medical Club.—President Taft has accepted the invitation of the Medical Club of Philadelphia to be its guest on the evening of April 21.

Gifts to Hospitals.—The will of the late Ellis H. Yarnall contains a contingent bequest of $200,000 to the Episcopal Hospital.——Under the will of Catherine Boyle, St. Mary's Hospital receives $5,076.67.

Personal.—Dr. E. Avery Newton, formerly of Philadelphia but now of Bad Nauheim, Germany, is taking a trip round the world.——Dr. W. E. Keplar has been appointed assistant medical inspector of the bureau of health.

Hospital Staff Election.—The Samaritan Hospital Staff has chosen the following officers: president, Dr. Jesse O. Arnold; secretary, Dr. Charles S. Barnes, and Chairman of the executive committee, Dr. Daniel J. Donnelly.

Weir Mitchell Lecture.—The second of the Weir Mitchell lectures of the College of Physicians, was delivered March 30, by Dr. Edmund B. Wilson, professor of zoology in Columbia University, on the "Cellular Basis of Heredity."

University Publication Discontinued.—The *Medical Bulletin of the University of Pennsylvania* ceased publication March 20 after an existence of twenty-three years. The bulletin was a monthly magazine which circulated largely among the medical alumni of the university, especially those living in Philadelphia.

Case of Beriberi.—A Norwegian vessel, which arrived at Marcus Hook Quarantine Station, March 23, was found to have a case of beriberi aboard. The sailor had been suffering for several weeks and no special effort at isolation had been made. He was sent to Marcus Hook Hospital and the other members of the crew were given a thorough examination.

German Hospital Addition.—On March 18, the cornerstone of the new $100,000 addition to the German Hospital was laid by Herman Hessenbruch, president of the institution. When finished the building will be used as a maternity hospital and nurses' home, will be a five-story granite and brick construction, fire-proof throughout, equipped with elevators and other modern conveniences and will accommodate sixty nurses.

Elections.—At the last meeting of the Philadelphia Neurological Society the following officers were elected to serve for 1911: president, Dr. Alfred R. Allen; vice-presidents, Drs. John H. W. Rhein and Samuel D. Ingham; secretary, Dr. George E. Price; treasurer, Dr. S. DeWitt Ludlum; councilors, Drs. James H. Lloyd, H. H. Donaldson and Francis X. Dercum. ——The officers of the Medicolegal Society for 1911 are: president, Dr. Lambert Ott; first vice-president, Clarence Loeb, Esq.; second vice-president, Dr. William D. Robinson; secretary, Dr. William T. Hamilton; treasurer, Dr. George M. D. Peltz; censors, Dr. Francis J. Kelly, James H. Wolfe, Esq., and Dr. Louis D. Bauer.

To Begin Work on Phipps Institute.—As soon as the contract can be made, the University will begin the erection of the Phipps Institute for the study and treatment of tuberculosis, which will be located at the northeast corner of Seventh and Lombard Streets. Plans for the building were filed with the Bureau of Building Inspection by the architect on March 16. The lot which the building will occupy extends from Lombard Street to Seventh Street, directly opposite Starr Garden Park. The building will be a five-story and basement fire-proof and brick structure with a frontage of 147 feet on Seventh Street from Addison to Lombard and a depth of 132 feet on Lombard Street. The main entrance will be on Seventh Street. The Lombard Street front will be built with two wings with a sunken garden between, the whole surrounded by iron railings. In the basement of the building will be a library, lecture hall, lavatories, mechanical rooms, etc. The second floor will have a large laboratory for experimental work and the third, fourth and fifth floors will be mainly devoted to large open-air wards. The accommodations will be such that treatment can be given to several indoor and outdoor patients. The cost of the building will be about $300,000.

Plans for New City Institutions.—On March 18, the mayor approved an ordinance, appropriating to his department $150,000 for the purchase of land that might be needed for public improvements. The mayor proposes using $135,000 to buy the Alexander Brown tract of wooded land, comprising 135 acres, adjoining the Torresdale Filtration Plant, for the purpose of building thereon an institution for the care of the feeble-minded and a home for indigent women. Instead of erecting one great building for the feeble-minded, the plans call for the erection of separate cottages with a central heat, light and power plant. The city already owns 55 acres of ground adjoining the house of correction, at Holmesburg, where it is proposed to build a home for indigent men. The city also owns the Byberry tract of 800 acres of unimproved land. This is to be the site of the Philadelphia Hospital for the Insane. The state will cooperate with the city in its establishment, for which appropriation bills are now pending in the legislature. This divorce of the almshouse and feeble-minded department from the Philadelphia General Hospital will give wider scope and development to that institution. It is proposed to furnish heat, light and power for the Holmesdale and Torresdale institutions from the power plants operated in connection with the house of correction and the Torresdale low-lift pumping station. There is nearly $800,000 already available for the establishment of these homes for the indigent and with the balance of $150,000 for the acquirement of land, municipal improvements can begin at once.

SOUTH CAROLINA

Meeting of State Society.—The annual convention of the South Carolina Medical Association will be held in Charleston, April 19-21.

Personal.—Dr. G. DeFoix Wilson, Spartanburg, charged with violating the health ordinance of the city by failure to report cases of small-pox, was exonerated when the case was tried. ——Dr. Isadore Schayer, Laurens, has been designated to inspect the property and personnel of the national guard of the state.

Penitentiary Health Conditions.—The senate has adopted the report of the medical affairs committee, with the recommendation that the State Board of Health be requested at once to make a thorough investigation, and to make such recommendations for the removal of the cause of complaint, if any such cause be found, as in their judgment will best preserve the health of the convicts confined in the state penitentiary.

County Physicians Elect.—At the annual meeting of the Laurens County Medical Society, held in Laurens, the following officers were elected: president, Dr. Thomas L. W. Bailey, Clinton; secretary-treasurer, Dr. Jesse H. Teague, Laurens; delegates to the state medical association, Drs. W. Dorroh Ferguson and Rolfe E. Hughes, Laurens, and alternates, Drs. Thomas L. W. Bailey, Clinton, and Jesse H. Teague, Laurens. ——Sumter County Medical Society, at its meeting in Sumter, elected Dr. H. Ashley Mood, president; Dr. William E. Mills, vice-president; Dr. Edwin R. Wilson, secretary-treasurer; and Dr. Charles J. Lemmon, delegate to the state medical association, all of Sumter.

SOUTH DAKOTA

New Hospital.—Physicians of Yankton and vicinity met at Sacred Heart Hospital, February 28, to inspect designs for the new hospital to be erected on Mount Marty. The building will have a frontage of 220 feet with wings of 80 feet, will be five stories in height, and estimated to cost about $250,000.

Society Charter Revoked.—On the recommendation of the councilors, the house of delegates of the South Dakota State Medical Association, February 21, revoked the charter of the Hot Springs (Tenth District) Medical Society on account of unprofessional conduct on the part of some of the members. The society had failed to take action, after being requested to do so

WISCONSIN

Home for Feeble-Minded.—A bill introduced in the legislature by Senator Hoyt provides for an appropriation of $150,000 for the purpose of securing a site of not to exceed 1,00 acres, near Milwaukee, for a state home for the feeble-minded

Unlicensed Practitioner Convicted.—Rev. J. P. A. Nordin head of Nordin Institute for Dependent and Deformed Children, Milwaukee, is said to have been found guilty of practicing medicine without a license, and fined $50 and costs.

One Institution for Tuberculosis.—At a recent meeting o the Milwaukee County Medical Society, a resolution introduced by Dr. Gilbert E. Seaman, approving the idea of th city to incorporate all institutions dealing in any way wit the tuberculosis problem under one general head, was adopted

Fraternity Election.—The Kappa Chapter of the Alph Kappa Kappa Fraternity held its annual election in Milwaukee March 17. Dr. Daniel Hopkinson, Milwaukee, was reelecte president; V. Brumbaugh, vice-president; P. Braman, recording secretary; W. Schnell, corresponding secretary, and P. R Noe, treasurer.

Election.—At the annual meeting of the Outagamie Count Medical Society, held in Appleton, March 7, Dr. Victor F Marshall, Appleton, was elected president; Dr. John J. Laird Black Creek, vice-president; Dr. Frank P. Dohearty, Appleton secretary-treasurer, and alternate-delegate to the state society; Dr. Gerald C. Maes, Kimberly, censor; and Dr. Charles D Boyd, Kaukauna, delegate to the state society.

Directors of Antituberculosis Association Meet.—At a meeting of the directors of the Wisconsin Antituberculosis Association, a new constitution and by-laws was adopted, and a ne board of directors was elected, which in turn elected th following officers: president, Dr. Mazyck P. Ravenel, Madison vice-presidents, Prof. Louis E. Reber, Madison; and Dr. Gustave Windesheim, Kenosha; secretary, Dr. Clarence A. Baer Milwaukee; treasurer, John H. Kopmeier, Milwaukee; an executive committee, the president, first vice-president, secretary, treasurer, and Dr. John W. Coon, Wales. It was reporte that $27,313.94 had been realized from the sale of Red Cros seals during the Christmas vacation.

GENERAL NEWS

The Study of Narcotics.—The American Society for th Study of Alcohol and Other Narcotics will hold its fortiet annual meeting in Baltimore, April 19 and 20. Histori addresses and scientific papers on laboratory and clinica research work on alcohol, inebriety and narcotics will be presented. Dr. Thomas D. Crothers, Hartford, Conn., is secretary

Service Schools Close.—The commencement exercises of th United States Navy Medical School were held, March 23, i Washington, when a class of thirteen was graduated.——Th Army Medical School, Washington, has been closed tw months in advance of the usual period in order that the service of the graduates may be utilized in the maneuvers o the Mexican frontier.

Missouri Valley Meeting.—The twenty-third s[illegible] meeting of the Medical Society of the Missouri Va[illegible] held in St. Joseph, March 16 and 17, under the pre[illegible] of Dr. Donald Macrae, Council Bluffs, Ia. On the first e[illegible] Dr. Henrich Stern, New York City, delivered the oration i medicine on "Decay of Nations." Dr. Oliver C. Gebhart, St Joseph, was elected treasurer to succeed Dr. Thomas B. Lacey Jr., Council Bluffs, resigned. A report of the scientific proceedings will appear in The Journal.

A Disclaimer.—The following members of the faculty o the University of Liverpool desire to disclaim any credit o responsibility attached to statements made or conclusion drawn in a book by Mr. H. C. Ross and Dr. J. W. Cropper just published by Messrs. John Murray and Sons, entitle "Induced Cell Division and Cancer:" R. J. Gibson, professo of botany; W. A. Herdman, professor of zoology; B. Moore professor of biochemistry; Dr. S. C. Sherrington, professor o *physiology* and J. Reynolds Green, lecturer on vegetable chemistry. These gentlemen state that they have had *no opportunity* of seeing the work either in manuscript or in proof.

Gastro-Enterologic Program.—The preliminary program for the fourteenth annual meeting of the American Gastro-Enterological Association, which is to be held in Philadelphia, April 18-20, contains a number of interesting titles, among which are the following: "The Relation of Symptoms to Pathologic Findings in Cancer and Ulcer of the Stomach," by Dr. Joseph Colb Bloodgood, Baltimore; "Operative Treatment of Impermeable Cardiospasm," by Dr. Willy Meyer, New York City;

"The Gastric Weak Line in Wounds of the Abdominal Wall," by Dr. Robert T. Morris, New York City; "Study of Anthropometry of Enteroptosis," by Dr. John C. Hemmeter, Baltimore; "The Cammidge Reaction in Tuberculous Cases," by Dr. Charles D. Spivak, Denver; and "Duodenal Ulcer," by Drs. Lewis Brinton, Philadelphia; James T. Pilcher, Brooklyn; John A. Lichty, Pittsburg, and A. L. Benedict, Buffalo.

Control of Bovine Tuberculosis.—The meeting of the International Commission on the Control of Bovine Tuberculosis was held in Buffalo, February 27, at which it was decided that the first task of the commission should be the preparation of material for a small pamphlet on the subject of bovine tuberculosis for the general public, especially stock owners, and embodying full statements of available information on the subject so far as it concerns stock owners in a practical way, and so far as such information is acceptable to the commission. The committee entrusted with the preparation of the pamphlet consists of Dr. Veranus A. Moore, Cornell University; Dr. John R. Mohler, Federal Bureau of Animal Industry; J. J. Ferguson, representing the American packers; Dr. Myron H. Reynolds, St. Paul, Minn., representing the American veterinarians; and Dr. F. Torrance, Manitoba, representing the Canadian veterinarians. The next meeting of the commission will be held in Toronto in August.

CANADA

New Bacteriologic Laboratory.—Plans for the new bacteriologic laboratory in the city hall, Toronto, were passed by the board of control, March 22, and an appropriation of $9,000 was made to cover the cost of construction.

Bequests to Hospitals.—By the will of the late Charles Burd, Montreal, $10,000 is bequeathed to the Montreal General Hospital; $5,000 to the Protestant Hospital for the Insane; $2,500 to the Western Hospital, and $2,000 to the Alexandria Hospital.

Personal.—Dr. Helen MacMurchy, Toronto, for the last six years editor of the *Canadian Nurse*, has resigned from that position.——Dr. John Gaven, Toronto, has returned from Florida.——Dr. George R. McDonagh, Toronto, returns from Barbadoes this month.——Dr. Thomas G. Roddick has been elected president of Alexandria Hospital, Montreal.

Hospital Notes.—Western Hospital, Montreal, admitted 1,291 patients in 1910, and treated 1,358. In the outpatient department 12,878 patients were treated.——The Royal Victoria Hospital, Montreal, admitted 4,309 patients during the year and cared for 4,532 in the outpatient department; 297 deaths occurred during 1910.——Alexandria Hospital, Montreal, treated 820 patients during the year with a mortality of 47.

The War Against Tuberculosis.—At the meeting of the Winnipeg Antituberculosis Society, March 14, the superintendent of the Ninette Sanatorium, reported that Winnipeg has the best record for tuberculosis cases. The secretary reported that addresses had been given on 22 occasions before clinics, societies, etc., and before 65 classes in Winnipeg public schools, and that in the same time 2,500 visits had been paid to 202 patients suffering from tuberculosis, of whom 48 died.

LONDON LETTER

(From Our Regular Correspondent)

LONDON, March 18, 1911.

Plague and Its Spread

Mr. James Cantlie, of the London School of Tropical Medicine, who has spent many years in the East where he helped to found a medical college for the Chinese, is well known as an authority on plague, and during recent years has been charged with the examination of every person in London suspected of plague, recently delivered a lecture on "Plague and Its Spread" before the Royal Society of Arts. The prevalence of plague in the world in epidemic form since 1894 was, he said, a matter of supreme interest to every nation. The question arose: has the virulence of the malady spent itself and may we look forward to abatement of the pandemic? The history of previous epidemics did not engender a hopeful answer; indeed the opposite obtained, for all previous outbreaks indicated the long continuance of plague in every community in which it had gained a hold. There were three stages of plague: (1) *pestis minor*, which was carried only by insects from diseased animals, always local, a household outbreak in fact, in which the pseudoplague bacillus is found in man; (2) bubonic plague, carried from man to man by insects; (3) pneumonic plague passing from man to man without the intervention of insects. Time was required for one plague type to change into another more virulent, until at last plague no longer required an animal host but became wholly a disease of man. An important point in the epidemiology of plague was that animals, chiefly rodents—the rat in many places, the marmot in north China and the squirrel in the United States—might suffer for years without infecting man, except in a sporadic way. In north China this had been proved to be the case and in any country where rodents were infected this might be expected.

Precautions in London Against Rat Plague

The following regulations "for the prevention of an outbreak of plague among rats at the docks" have been adopted: All ropes and mooring tackle shall be fitted with such effective guards as will prevent access of rats from the vessel to the shore. For breach of this regulation the penalty is one not exceeding $25. 2. All possible means shall be adopted for catching and destroying rats during the stay of any vessel in dock. All empty cases and barrels shall be examined before being landed to ensure that no rats are contained therein. Any rats caught on board the vessel shall be killed and then placed in bucket of strong disinfecting solution and burnt in the ship's furnace. The same penalty is enforced for breach of this regulation. 3. When the discharge of cargo or the landing or embarking of passengers is not proceeding only one gangway shall be permitted between the vessel and the shore. The end near the vessel shall be whitened for a length of 10 feet. The same penalty is enforced for breach of this.

The Small-Pox Epidemic in London

The number of cases of small-pox which have occurred in London in the present outbreak now numbers fifty-eight. The London County Council has resolved that for a period of three months chicken-pox shall be a reportable disease, experience having proved that slight cases of small-pox are sometimes mistaken for chicken-pox.

The New House of the Royal Society of Medicine

In the heart of medical London a handsome building is being erected which will provide ample accommodation for the Royal Society of Medicine for many years, even if the membership of the society continues to increase in the manner expected. The area of ground is nearly 10,000 square feet. The building will consist of basement, ground floor and three upper floors. On the ground floor will be a spacious vestibule and two halls—one capable of holding about 500 and the other 150 persons and patients' rooms for each sex. The whole of the first floor will be occupied by the library, and the offices of the secretary, editor and clerks. The library will be 110 feet long, 28 feet wide and 19 feet high. The periodical room will be an annex. There will be a gallery all round and a mezzanine room with additional tables for readers. On the third floor will be a museum, a room equipped for the examination of specimens and histologic work, a smoking room, and a tea and conversation room. The cost will be $150,000, of which $60,000 has been promised or collected.

PARIS LETTER

(From Our Regular Correspondent)

PARIS, March 17, 1911.

Dedication of the Monument to Professor Cornil

March 5, at the Ecole pratique of the Faculté de médecine the monument in honor of Professor Victor Cornil was dedicated. The ceremony was presided over by M. Fallières, the president of the republic, and a great number of professors and political notables were present, Cornil having been a deputy and senator. Among the addresses given was one by Professor Landouzy, who mentioned that Cornil was the real founder of pathologic histology in France.

The monument is the work of Dr. Paul Richer, who is a member of the Académie de médecine and the Académie des beaux-arts. The design is an architectural one, with a laurel-decorated summit surmounted by the bust of Cornil. The center is occupied by a bas-relief representing Cornil's pathologic-anatomic laboratory, with flasks of reagents and microscopes on tables, and a body stretched on a slab ready for the autopsy. An allegorical figure of Truth, seated by one of the angles of the base in a grave and meditative pose, holding a palm-leaf, seems to glorify the fruitful labor of the master who has found in the analysis of diseased organs the true causes of death. The bust is in marble, the architecture in stone, and the bas-relief and the allegorical figure in bronze;

the base bears the inscription *A Victor Cornil, ses élèves, ses amis.* "To Victor Cornil from his pupils and friends;" on the posterior face of the monument is the inscription: *Victor Cornil, 1837-1908; professeur d'anatomie pathologique à la Faculté de médecine de Paris, 1882-1907.*

Salvarsan and Advertising

As was to have been expected, the discussions about Ehrlich's discovery, even (not to say especially) in non-medical circles, have given an opening to all kinds of charlatans to make use of the famous German scientist's name for their advertisements. For some time supposedly scientific articles on salvarsan have been appearing in the lay press. They state that "all syphilitics without exception are amenable to 606," that "606 is the veritable vaccine of syphilis," etc. Finally, comes the declaration that to obtain the maximum efficacy it is necessary to send to some "serotherapeutic institute" or "laboratory of biology." It is unnecessary to say that these are institutes and laboratories only *in name.*

Personal

On March 7 the Académie de médecine elected a member in the section of anatomy and physiology to replace Professor Farabeuf, who died last August. The new member is Dr. Prenant, who was, three years ago, chosen to be professor of histology of the Faculté de médecine de Paris and who was previously professor at the Faculté de médecine de Nancy.

In the session of March 14 the Académie de médecine elected two national correspondents in the section of medical pathology. These were Dr. Lannois, adjunct clinical professor of laryngology, otology and rhinology at the Faculté de médecine de Lyon, and Dr. Maurel, professor of experimental pathology at the Faculté de médecine de Toulouse.

On March 13 the Académie des sciences elected Professor Pawlow of St. Petersburg as correspondent in the section of medicine and surgery.

Professional Responsibility of Surgeons and Physicians

At a meeting of the Association de l'internat des hôpitaux de Paris on March 17 this timely question was treated from the legal point of view by M. Colin, professor at the Faculté de droit de Paris. In general, M. Colin mentioned that two conditions were necessary to make the surgeon responsible: the first was material or moral harm to the patient; the second was fault on the part of the surgeon, which might be either medical or non-medical. The latter would be within the competence of the ordinary judge. But how and by whom should serious medical fault be judged? M. Colin believes that an expert alone can appreciate a medical fault, and that his rôle is not always easy. One runs the risk of stifling all initiative and arresting progress by condemning a new treatment or an audacious procedure. M. Colin mentioned the reply of Velpeau in regard to the first accidents due to chloroform: "It is not the surgeons who have need of chloroform; it is the patients." After reviewing the jurisprudence on this subject, which is not well defined, M. Colin advised physicians and surgeons to form associations for mutual insurance as the only means of defending themselves, for they are now often the prey of blackmailers.

BERLIN LETTER

(From Our Regular Correspondent)

Berlin, March 10, 1911.

Death of van 't Hoff

A few days ago in a suburb of Berlin, there died at the age of 59, from a lung disease of some years' standing, the renowned chemist and honorary professor in the Berlin university, J. H. van 't Hoff. [See editorial, March 18, page 818.] He was born in Rotterdam in 1852 and studied in Leyden, Bonn, Paris and Utrecht, devoting himself to the natural sciences; he was appointed privat-docent at the latter university in 1876, and in 1888 became the founder and chief of the laboratory for physical chemistry. In 1896 he accepted a call to Berlin as regular honorary professor. His work was epoch making in the development of physical chemistry. The most important of his scientific works are his new thory of solution in which the identity of the gas pressure and the osmotic pressure was demonstrated and a new method of measuring the molecular weight was discovered, and his investigations of the spatial relations of the atoms, with which he laid the foundations of stereochemistry. Also for medicine his work on osmosis has been most fruitful in advancing our understanding of the processes of metabolism. Van 't Hoff was a member of the academy of sciences, and most of the academies of the world, knight of the order "pour le mérite" and recipient of one of the Nobel prizes.

Bill Against Quackery

The committee of the Reichstag appointed to consider the bill for restriction of unqualified practice of medicine, contrary to expectation is deciding on considerable concessions which weaken the original draft of the bill. In fact, the conservatives and the representatives of the center are inclined to support all kinds of quackery, and especially the form of mystical treatment (cure by prayer, by laying on of hands, rubbing, magnetism and the like), and express views that often unintentionally have a ludicrous effect and show that scientific ideas are not very widespread even among intelligent people. One member belonging to the center group stated that he had lately come to question whether magnetism might not actually prove a curative agent. As evidence, he brought a long letter from a young lawyer in which the author averred that by means of therapeutic magnetism he had been enabled to pass his examination for the bar, and that he had also been cured of a nervous affection, so that he was able to marry. Another assured the committee that a person in high position has recommended as a remedy against epilepsy the pulverized feces of a still virgin billy goat. Hence it is not strange that the original bill is weakened and that magnetism has been separated from the class of forbidden mystic curative measures. Meanwhile, one may cherish the hope that the essential part of the bill will be accepted, and that some good will be secured for the public health so far as it suffers from quackery.

A University at Frankfort

For many years those interested at Frankfort-on-Main have been endeavoring to expand the present medical and other institutions into a university. On the part of the government there is no great tendency to increase the number of universities, and it must be admitted that Frankfort does not possess favorable conditions for a new foundation. The university of Marburg and that of Giessen are situated in the near vicinity and would surely be injured by the new university. In large cities overcrowding of the lecture halls soon manifests itself, so that instruction suffers, and this condition would very probably soon be the rule at Frankfort. To be sure, the consent of the government may be facilitated by the circumstance that Frankfort would furnish the means for founding and supporting the university institutions. These would not need to be much increased, at any rate in the medical field, as the most necessary teaching places for this faculty are already provided in the municipal hospitals, in the "Georg-Speyer house," in the institute for experimental therapy, in the Edinger Institute, etc. The proposition submitted by the city government has only three university departments in view: law, philosophy and medicine.

New Bill on Cremation in Prussia

As I mentioned in a previous letter, the opposition in religious circles to the legal permission for cremation in Prussia is to be disregarded by the government, and a bill for its legalization has been very lately introduced into parliament. According to the bill, cremation will be permitted only in establishments licensed by the national police. The permission may be revoked if the arrangements do not correspond to technical requirements, or if a suitable room for the reception of corpses is not provided, or if there are objections on the part of the police. The cremation can take place only when the following conditions have been complied with: an official death certificate, an official medical certificate of the cause of death, proof that the deceased has ordered the cremation of his body, and a certificate of the local police authorities at the place of death that there are no objections to cremation, and especially that there is no suspicion that the death was due to crime. The order is effective only if the deceased was 16 years of age, and it cannot be made by a repesentative. A necropsy is to be held if one of the attending physicians considers it necessary in order to establish the cause of death. Penalties are provided for the transgression of this and other provisions. In the prologue of the bill it is pointed out that the objections to cremation from the standpoint of justice, and especially of criminal law, are no longer of great importance in the present state of medical or chemical science, while the interests of religion will not be materially affected by the sanction of cremation. The bill will undoubtedly be strongly opposed by the numerous orthodox representatives in the Prussian parliament, who are especially among the conservatives and the center, but it is to be hoped that the measure will finally be passed.

VIENNA LETTER

(From Our Regular Correspondent)

Vienna, March 13, 1911.

High Morbidity and Mortality in Vienna

The health report for the first part of the year 1911 contains unpleasant news for the inhabitants of this city. The percentage of diseases and deaths has not been so bad for more than twenty years. The present epidemic of influenza is responsible for these conditions. The last epidemic was in 1889, when the mortality was 16 per cent. Since then we have had only occasional outbreaks. This winter, however, there were more than 19,000 persons laid up at the same time—at least so many have been reported by the physicians. Apart from influenza, other epidemic diseases were also prevalent during January and February, although they were all of a mild type. The doctors practicing among that part of the population which is entitled to free medical aid, have reported 335 cases of scarlet fever, 202 of diphtheria, fourteen cases of typhoid fever, 113 of erysipelas, 519 of measles, 160 of pertussis, 335 of varicella, and 227 of parotitis. There were 851 cases of fresh infections of tuberculosis and scrofulosis reported, while 1,214 persons of this class suffered from fresh disease of the alimentary canal. There died in this month of January 3,493 persons, against 2,915 in December last, and 2,790 in January last. The increase of deaths was due to influenza, as manifested by the numerous deaths caused by diseases of respiratory organs; 437 more than last year at the corresponding time. The distribution of deaths among the two sexes was equal. The report for the first week of March, however, shows that a marked and definite improvement, consequent on the improved weather, has taken place already.

Protection of Sick Children in Hungary

The present condition of the sanitary and charitable institutions for diseased children is far from satisfactory. The comparison with other countries shows how backward Hungary is in this respect. There are only ten children's hospitals, with 850 beds, at the disposal of the physicians, for a population of 20,000,000! There is not a single sanatorium for tuberculous children, while there are forty such institutions in Germany. Only 100 cripples in Hungary against 3,000 in Germany are cared for in special houses, where they learn to work and earn part of their living. Even worse conditions prevail as regards deaf mutes and blind children; although there are more than 6,000 such individuals in the kingdom, only a few hundred are looked after in a regular way. Equally bad are the provisions for idiotic and mentally defective children. Merely four small homes and now and then a class on nursing of such patients represent the entire social care of the state for its defective offspring.

Foot-and-Mouth Disease in Austria

During this last autumn and winter foot-and-mouth disease was prevalent among the cattle in Austria, and a large percentage of the animals had to be killed. Naturally, the quality and quantity of the milk-supply for the capital was severely handicapped by these conditions, and the supply of meat, too, was restricted. The health authorities took in time the necessary precautions to prevent a spread of the infection to human beings. But in spite of all care, sporadic cases appeared, and even yet a case is reported now and then. As a rule, the patients are affected only in a mild degree, while the animals suffer severely. The mode of transmission to the persons could not be ascertained, but it is safe to assume that milk and butter are responsible for it. It may be mentioned, by the way, that the first authentic case of this disease this year was in the wife of a medical man. Adults chiefly were the victims this time, and no fatal case was reported.

Marriages

James H. Goad, M.D., Ellston, Ia., to Miss Rosa Watts of Ross, Ind., March 16.

Glenn Wheeler, M.D., and Anna Marie Regan, M.D., both of Portland, Ore., March 15.

Benjamin Spafford Barnes, M.D., Shenandoah, Ia., to Miss Pansy Mincer of Hamburg, Ia., March 9.

Boyd T. Williams, M.D., to Mrs. Virginia Bradley, both of Hudson, Wis., at St. Paul, Minn., March 11.

Deaths

William Palmer Peirce, M.D. New York University, New York City, 1852; formerly a member of the American Medical Association, and National Association of Railway Surgeons; vice-president of the Illinois State Medical Association in 1875; surgeon of the Eighty-Eighth Illinois Volunteer Infantry, and later chief surgeon of the First Brigade and Second Division, Fourth Army Corps during the Civil War; a member of the Illinois House of Representatives in 1869, and of the State Senate in 1872; mayor of Hoopeston in 1889 and 1890; local surgeon of the Lake Erie and Western Railway, and a member of the local board of pension examining surgeons; died at his home in Hoopeston, February 20, from diabetes, aged 79.

James Milton Peck, M.D. Vanderbilt University, Nashville, Tenn., 1882; of Arlington, Ky.; a member of the American Medical Association; and formerly president of the Carlisle County and Southwestern Kentucky medical societies; and vice-president of the Kentucky State Medical Association; health officer and referee for Carlisle County; died in Riverside Hospital, Paducah, March 14, from abscess of the liver and general sepsis, following an operation for appendicitis, three months before, aged 53.

Edward Fiske Ashley, M.D. Yale University, 1900; a member of the American Medical Association; bacteriologist of the Quarantine Hospital and assistant to the health officer of the port of New York; contracted cerebrospinal meningitis while making autopsies on the infected steerage passengers of the steamers *Patras* and *Martha Washington*, and died from the disease, at Swinburne Hospital, New York Harbor, March 21, aged 34.

Benjamin Anthony Plant, M.D. University of California, San Francisco, 1886; formerly an official of the health department of San Francisco; surgeon of the Pacific Mail Steamship Company for two years; and for a like period resident physician at the state penitentiary, Folsom; division surgeon of the Southern Pacific System; died at his home in Santa Cruz, February 16, from bronchopneumonia, aged 45.

Isaiah Baker Bolton, M.D. Hahnemann Medical College, Philadelphia, 1873; a veteran of the Civil War; formerly chairman of the board of health and city physician of Newburyport, Mass.; died at his home in Los Angeles, Cal., January 11, from septicemia, due to pyothorax, following a pleurisy with effusion nine years before, aged 66.

William Witry Jungels, M.D. Dearborn Medical College, Chicago, 1905; formerly a member of the American Medical Association; and an ambulance surgeon of Chicago; who moved to Dubuque, Ia., six months ago; died in an ambulance in that city, while being taken to Mercy Hospital, March 13, from nephritis, aged 33.

Charles Avery Hart, M.D. Western Pennsylvania Medical College, Pittsburg, 1899; a member of the Butler County (Pa.) Medical Society; died suddenly in Butler, March 14, from heart disease, aged 33. Butler County Medical Society, at its meeting, March 14, adopted resolutions of sympathy and regret.

Thomas Kerr McKee, M.D. Medico-Chirurgical College of Philadelphia, 1895; of Grove City, Pa.; a member of the Medical Society of the State of Pennsylvania; for two years a practitioner of Tulsa, I. T.; died in the West Penn Hospital, Pittsburg, Pa., February 5, from acute nephritis, aged 52.

Henry A. Rodebaugh, M.D. Starling Medical College, Columbus, O., 1875; of Columbus; a member of the American Medical Association; and formerly medical director of sanatoria at Marysville and Columbus; died in the Lawrence Hospital in that city, March 17, from disease of the kideny, aged 55.

Raymond W. Brown, M.D. University of Pennsylvania, Philadelphia, 1909; intern in the Hudson Street Hospital, New York City; died, March 24, from cerebrospinal meningitis, contracted, it is believed, while combating the disease recently brought to New York City on a Greek steamer, aged 25.

Robert David Craighead, M.D. Indiana Medical College, Indianapolis, 1871; for fourteen years house physician at Dr. Strong's Sanitarium, Saratoga Springs, N. Y.; and afterward one of the proprietors of Craig Hall, Atlantic City, N. J.; died in that city, March 11, from pneumonia, aged 63.

John B. Richmond, M.D. Jefferson Medical College, 1852; surgeon of the Twenty-Seventh New Jersey Volunteer Infantry during the Civil War; and afterward president of the Hibernian Fire Insurance Company; died at his home in Newark, N. J., March 12, from heart disease aged 81.

Charles Howard Bradley, M.D. Harvard Medical School, 1882; a member of the American Medical Association; formerly president of the Las Vegas (N. Mex.) Medical Society; for fifteen years a resident of Las Vegas; died at his home, March 3, from pneumonia, aged 52.

Nathan A. Foster (license, Missouri, 1883); for more than fifty years a practitioner of Ralls county; who was tendered a banquet by the Ralls County Medical Society, of which he was the oldest member, a few months ago; died at his home in Center, March 10, aged 84.

Charles Salter Wheeler, M.D. University of Vermont, Burlington, 1879; a member of the American Medical Association, and for several years a member of the state pension board; died at his home in Flushing, Mich., March 10, from cirrhosis of the liver, aged 54.

Raymund H. Phillimore, M.D. McGill University, Montreal, 1893; a district physician of Montreal; medical inspector of schools; and surgeon-lieutenant-colonel Seventh Hussars Canadian Militia; died recently in Montreal, from cancer of the throat, aged 53.

Peter J. Roebuck, M.D. University of Pennsylvania, Philadelphia, 1860; a member of the American Medical Association; for two years state senator; president of the Farmers National Bank of Lititz, Pa., died at his home, March 9, from pneumonia, aged 73.

Charles Wheeler McConnell, M.D. University of Pennsylvania, Philadelphia, 1897; a member of the American Medical Association, and pathologist to Altoona Hospital; died at his home in that city, March 12, from cirrhosis of the liver, aged 40.

James Milton Foster, M.D. Berkshire Medical College, Pittsfield, Mass, 1852; for nearly half a century a practitioner of Wilbraham, Mass.; a member of the school committee for several years; died at his home, March 17, from heart disease, aged 82.

J. W. Bennett, M.D. Hospital Medical College, Eclectic, Atlanta, 1910; of Augusta, Ga., was thrown from his buggy, March 13, in a runaway accident, at North Augusta, and died a few minutes later in the Margaret Wright Hospital, Augusta, aged 46.

Frederick Clinton Taylor, M.D. Cleveland College of Physicians and Surgeons, 1891; of Cleveland; a member of the American Medical Association, and a member of the staff of the Lutheran Hospital; died in Biloxi, Miss., March 9, aged 41.

Thomas Jefferson Kelley, M.D. Medical College of Georgia, Augusta, 1881; Bellevue Hospital Medical College, 1884; of Tennille, Ga., in a quarrel over the disciplining of his son, by a school teacher, March 10, was shot and instantly killed, aged 50.

Joshua Way, M.D. George Washington University, Washington, D. C., 1859; for many years a practitioner in Monroe and Bellevue Counties, O.; died at the home of this daughter in Woodsfield, March 9, from carcinoma of the liver, aged 73.

John Bryan Ward Nowlin, M.D. Jefferson Medical College, 1857; surgeon in the Confederate army during the Civil War; for forty years a practitioner of Nashville, Tenn.; died at his home in that city, March 3, from influenza, aged 74.

Alexander Fekete, M.D. Washington University, St. Louis, 1854; assistant surgeon and surgeon of the Fifth Missouri Cavalry *during* the Civil War; postmaster of East St. Louis, in 1889; died at his home, February 28, aged 83.

John Henry Hieber, M.D. Cincinnati College of Medicine and Surgery, 1871; a hospital steward of volunteers during the Civil War; died at his home in Pittsburg, Pa., March 11, from enlargement of the liver and *spleen*, aged 67.

Cortland Butler Rockwell, M.D. Chicago Homeopathic Medical College, 1883; of Chicago; who served in the Navy during the Civil War; died in a sanitarium in Kenosha, Wis., March 16, from valvular heart disease, aged 69.

John Henry Sackrider, University of Buffalo, N. Y., 1878; a member of the Medical Society of the State of New York, and health officer of East Randolph; died at his home in that place, March 12, from neuritis, aged 63.

Maurice Munker, M.D. College of Physicians and Surgeons, New York City, 1907; of New York City, died at the home of his parents in Steubenville, O., March 4, from septicemia due to an operation wound, aged 27.

Jones B. Hargrove, M.D. University of Alabama, Mobile, 1885; of Natchitoches; while en route to a sanitarium in Shreveport, died on a Louisville and Arkansas train, March 10, from malarial fever, aged 46.

Harry Burton Kuhns, M.D. Western Pennsylvania Medical College, Pittsburg, 1890; a member of the Medical Society of the State of Pennsylvania; died at his home in Neale, March 5, from tuberculosis, aged 45.

Hosias Schiemann, M.D. Universities of Kasan and Dorpat, Russia, 1889; of New York City; died in Mount Sinai Hospital, March 10, from myocarditis following a compound fracture of the femur, aged 45.

Stephen A. Ireland, M.D. Starling Medical College, Columbus, O., 1884; a member of the American Medical Association; died at his home in Washington Court House, O., January 25, from pneumonia, aged 62.

Robert Silvester Kelso, M.D. Rush Medical College, 1864; a member of the American Medical Association; a veteran of the Civil War; died at his home in Joplin, Mo., March 12, from influenza, aged 76.

Alexander R. Gray, M.D. Jefferson Medical College, 1855; a surgeon of volunteers during the Civil War; died in his room in the Jenkintown House, Jenkintown, Pa., March 12, from heart disease, aged 78.

Frank A. Van Sickle, M.D. Detroit (Mich.) College of Medicine, 1892; a member of the American Medical Association; died at his home in South Frankfort, Mich., March 10, from septicemia, aged 46.

Laura Cowgill Bates, M.D. Northwestern University Woman's Medical School, Chicago, 1885; formerly of Chicago; died at her home in Pasadena, Cal., March 15, from cerebral hemorrhage, aged 62.

John L. Witt, M.D. St. Louis College of Physicians and Surgeons, 1890; (license, Iowa, 1886); for many years a practitioner of Logan, Ia.; died in a hospital in St. Louis March 3, aged 56.

Columbus V. Massey, M.D. American Medical College, Eclectic, St. Louis, 1878; a member of the American Medical Association; died at his home in Chicago, March 20, from heart disease, aged 62.

Harrison Andrew Lyding, M.D. Rush Medical College, 1910; of Chicago; an intern in Michael Reese Hospital; died in that institution, March 20, from scarlet fever contracted from a patient, aged 23.

Edwin Samuel Howe, M.D. University of Vermont, Burlington, 1880; formerly supervisor of Blackbrook, N. Y.; died at his home in Au Sable Forks, N. Y., March 4, from heart disease, aged 55.

Lee R. Ashley, M.D. University Medical College of Kansas City, Mo., 1897; a member of the Kansas Medical Society; died at his home in Pleasanton, February 8, from typhoid fever, aged 38.

Joel Allen (license, years of practice, Illinois, 1877); surgeon of the Seventy-Seventh Illinois Volunteer Infantry during the Civil War; died at his home in Pontiac, March 9, from influenza, aged 83.

Arthur John Perry Howe, M.D. Long Island College H[illegible] in Brooklyn, 1909; house physician of St. Mary's Hospital, [illegible]ken, died at his home in Brooklyn, March 18, from hear[illegible]ease, aged 27.

John V. Baird, M.D. Eclectic Medical Institute, Cincinnati, 1892; for two terms a member of the Indiana legislature; died at his home in Albany, March 12, from cerebral hemorrhage, aged 60.

Ernest McCue Thrift, M.D. University College of Medicine, Richmond, 1898; a member of the Medical Society of Virginia; died at his home in Madison, March 6, from pneumonia, aged 37.

Joseph L. Brown (license, Washington); a pioneer practitioner of Tumwater where he located in 1879; died at the home of his daughter at Black Lake, Olympia, Oct. 5, 1910, aged 82.

S. Albert Fishblate, M.D. Eclectic Medical College of the City of New York, 1879; of Pittsburg; died at the home of his sister in that city, February 23, from locomotor ataxia, aged 55.

William Thomas Masterson, M.D. Louisville (Ky.) Medical College, 1890; of Birmingham, Ala.; died at the home of his sister in Oakman, Ala., March 17, from cerebral hemorrhage, aged 55.

John W. Nelms, M.D. Southern Medical College, Atlanta, 1889; for twelve years sheriff of Fulton County, Ga.; died suddenly at his home in Atlanta, February 28, from heart disease.

Edwin Franklin Burkert, M.D. Medical College of Ohio, Cincinnati, 1884; of Dayton, O.; died in the Dayton State Hospital, Sept. 21, 1910, from acute confusional insanity, aged 53.

Daniel C. Badgeley (license, years of practice, West Virginia); a practitioner of Simpson for more than a quarter of a century; died at his home, March 5, from cancer, aged 80.

Brewerton Munro Lebby, M.D. Medical College of the State of South Carolina, Charleston, 1860; died at his home in Sumter, S. C., Sept. 4, 1910, from laryngitis, aged 77.

Flinn Browning B. Ilderton, M.D. Medical College of the State of South Carolina, Charleston, 1881; died at his home in Summerville, S. C., Dec. 13, 1910, from pneumonia, aged 56.

Samuel Hamilton Frazer, M.D. Eclectic Medical College of the City of New York, 1879; formerly of Newark, N. J.; died in Saratoga Springs, N. Y., February 24, aged 67.

Samuel Mauffette, M.D. Laval University, Montreal, 1903, of Montreal, died in the Hôtel Dieu, Montreal, in October, 1910, from the effects of gunshot injury, aged 32.

Charles Sedgewick Rounsevel, M.D. Hahnemann Medical College, Philadelphia, 1882; died at his home in Nashua, N. H., Nov. 7, 1910, after a surgical operation, aged 71.

Emily Pardee-Disbrow, M.D. New York Medical College and Hospital for Women, New York City, 1875; died at her home in South Norwalk, Conn., Nov. 30, 1910, aged 67.

David W. Jones, M.D. Eclectic Medical College of Pennsylvania, Philadelphia, 1870; of Hagerstown, Md.; died at the Bellevue Home, in that city, March 4, aged 84.

Martin H. Cassell, M.D. Jefferson Medical College, 1868; a veteran of the Civil War; died in his apartments in Davenport, Ia., March 18, from heart disease, aged 65.

Millard F. Brown, M.D. Indiana Medical College, Indianapolis, 1873; an early resident of the town of Lenox, Ia.; died at his home in that city, March 2, aged 61.

John Wesley Filkins, M.D. Northwestern University Medical School, Chicago, 1866; of Seattle, Wash.; died in the Pasadena (Cal.) Hospital, March 7, aged 62.

Foster Fish Robinson, M.D. Kentucky School of Medicine, Louisville, 1877; died at his home in St. Louis, January 10, from valvular heart disease, aged 58.

B. Blastus Robison, M.D. Tulane University, New Orleans, 1892; died at his home in Godley, Tex., June 4, 1910, from cancer of the stomach, aged 45.

George Adelbert Walters, M.D. Rush Medical College, 1895; died at his home in Wesley, Ia., March 14, from diabetes complicated by pneumonia, aged 40.

Linn Henry Corey, M.D. University of Vermont, Burlington, 1905; died at his home in Woodstock, Vt., Nov. 27, 1910, from intestinal tuberculosis, aged 32.

Orpha Desiah Baldwin Bruce, M.D. Boston University School of Medicine, 1885; died at her home in Tampa, Fla., Dec. 10, 1910, from anemia, aged 59.

Reuben C. Hoover, M.D. Pennsylvania Medical College, Gettysburg, 1843; died at his home in Osborn, O., March 19, from cancer of the face, aged 89.

George W. Andrews, M.D. Western Reserve University, Cleveland, 1875; died at his home in Ramsey, Ill., March 10, from pneumonia, aged 59.

Maurice John Wiltse, M.D. University of Vermont, Burlington, 1898; died at his home in Burlington, March 2, from locomotor ataxia, aged 46.

John William Barry, M.D. Eclectic Medical Institute, Cincinnati, 1879; died at his home in Springfield, O., Nov. 3, 1910, from nephritis, aged 64.

John O'Ferrall, M.D. Cincinnati College of Medicine and Surgery, 1863; died at his home in Danville, Ill., March 7, from nephritis, aged 74.

Francis Sterling Mudd, M.D. Tulane University, New Orleans, 1883; died at his home in Lafayette, La., Oct. 29, 1910, aged 81.

Frederick W. Dantzler, M.D. South Carolina; died at his home near Holly Hill, June 15, 1910, from cirrhosis of the liver, aged 64.

Joseph T. Miller, M.D. Jefferson Medical College, 1871; died at his home in Hartford, Ky., March 11, from pneumonia, aged 71.

Lonzo F. Brown, M.D. Medical College of Indiana, Indianapolis, 1879; of Alamo; died in Indianapolis in November, 1910, aged 58.

Association News

THE LOS ANGELES SESSION

Mountain and Seaside Hotel Accommodations Available

Dr. H. Bert Ellis, Chairman of the Committee on Arrangements, writes that, in addition to the hotel accommodations already announced for the Los Angeles session, those who may desire to stay either at the seashore or near the mountains will be given special rates at the Hotel Maryland at Pasadena, and the Hotel Virginia at Long Beach.

The Maryland is situated in Pasadena, 9 miles from Los Angeles. It is a first-class, homelike place and special rates have been made which include transportation, both ways, via the electric lines, between Pasadena and Los Angeles. Trains run every ten minutes.

The Hotel Virginia is a fire-proof, first-class, modern hotel, directly on the beach at Long Beach, and is reached from Los Angeles via the Pacific Electric Lines by trains every twenty minutes. The run takes forty minutes.

Members and their families and friends will find either of these cities very delightful places to stay during the meeting, and with the excellent train service no inconvenience will be experienced in reaching the meetings. Accommodations should be arranged for in advance.

THE SCIENTIFIC EXHIBIT

The Outlook for this Important Feature at the Los Angeles Meeting

The remoteness of the meeting place has been in no sense discouraging to the prospect for the Scientific Exhibit, at the coming session of the Association. In this as in other phases of the prospective meeting, the western men are alert to their obligations, having already assured liberal contributions. Dr. Stanley P. Black, Los Angeles, and Dr. William Ophuls, San Francisco, are looking after prospective exhibits from the coast region. The middle west has also promised commendable patronage. Dr. William A. Evans, Chairman of the Section on Preventive Medicine and Public Health, is seeking to do what we have striven at different times to persuade chairmen of sections to undertake, viz.: to coordinate the work of the sections with that of the exhibit. They should supplement each other.

A common fallacy in the minds of those who might exhibit, is the impression that only large collections are desired. The small research exhibit to which the gold medal was awarded last year, was offered at a late hour, with a modest apology and request that it be given a little corner somewhere. Institution and society collections must necessarily occupy the most prominent place in the Scientific Exhibit, but the small individual exhibit is also important. The committee is very anxious to encourage the latter.

Certificates of honor will be given to a few of the exhibits having superior merit. Medals and cash awards will be offered as detailed below.

1. Gold medal for best research exhibit dealing with any problem in the fundamental medical sciences.
2. Gold medal for the best exhibit on the basis of general excellence, from the standpoints of care in preparation, completeness and instructiveness.
3. Cash award of $100 for the best series of not less than six original cartoons dealing with any or all of the following health problems.
   (a) Insects in the causation of disease.
   (b) Beneficent effects of vivisection.
   (c) Pure food, and adulterated or contaminated foods.

The Committee on Scientific Exhibit reserves the right to purchase any of the cartoons offered in competition, at the rate of $10 each.

Those cartoons on which the award is made, become the property of the Scientific Exhibit. Other cartoons will be returned, if so desired, to the artists submitting them.

FRANK B. WYNN, M.D., *Indianapolis*,
Director of the Scientific Exhibit, American Medical Assn.

The Committee on a National Department of Health

President Welch has appointed the following as the Committee on a *National Department of Health:*

Dr. Herman M. Biggs, New York City.
Dr. S. G. Dixon, Harrisburg, Pa.
Dr. W. A. Evans, Chicago.
Dr. J. N. Hurty, Indianapolis.
Dr. J. N. McCormack, Bowling Green, Ky.
Dr. H. P. Walcott, Cambridge, Mass.
Dr. William C. Woodward, Washington, D. C.

Dr. Welch, by action of the House of Delegates, is also a member of the committee.

A preliminary meeting of the committee was held at New York on March 25, and an organization effected by electing Dr. Welch, chairman, and Dr. Woodward, secretary. After the discussion of some preliminary matters, the committee adjourned to meet in the building of the New York City Health Department, at 10:30 a. m., Saturday, April 1.

"The Propaganda for Reform"

In This Department Appear Reports of the Council on Pharmacy and Chemistry and of the Association Laboratory, Together with Other Matter Tending to Aid Intelligent Prescribing and to Oppose Medical Fraud on the Public and on the Profession.

DR. BERTHA C. DAY

A Mail-Order Medical Faker Specializing on the Diseases of Women

A study of the multitude of mail-order medical fakes makes plain one fact: Few of such concerns are owned by the renegade physicians whose names adorn the stationery of the companies. Most companies of this kind are organized and capitalized by shrewd—and often unscrupulous—business men. These companies are run solely and only for profit; the health or well-being of the victim who seeks their aid is a matter of indifference. It is not the state of the patient's health that concerns these harpies, but the condition of his pocketbook; it is not his sufferings they seek to relieve him of, but his money. The business is a commercial one; pills and tablets bought by the million from pharmaceutical houses; form letters skilfully designed to imitate either hand-writing or typewriting; testimonials; lists of names of "easy marks" purchased from letter brokers; unscrupulous physicians whose incompetency has made them failures in the honorable practice of medicine and who are willing to sell their birthright of professional honor for a miserable mess of pottage—these are the stock in trade of mail-order medical fakers.

In Fort Wayne, Ind., there are two mail-order medical concerns said to be doing a large and profitable business, and to be owned and operated by one William C. Griffin, a dealer in teas, coffees, etc. These are the J. W. Kidd Co., which "treats" anything from consumption to corns and the Dr. Bertha C. Day Co., which makes a "specialty" of "diseases of women." There is another "diseases of women" mail-order fake in the same town run by a Dr. Luella McKinley Derbyshire. It is said that the Derbyshire concern used to be owned by Griffin, but was purchased by Dr. Derbyshire about 1903. From a business standpoint, it seems rather unkind for Griffin to sell out a "female specialist" mail-order business and later start a competitive house. In 1906, Dr. Derbyshire was arraigned in the Federal courts on the charge of sending obscene matter, in the form of consultation blanks, through the mails. Her defense was, according to the papers, that the blanks were the same as those which had been used by Griffin for some years before she purchased the business from him, and that she "understood that a competent lawyer had gone over the blanks and found that there was nothing unmailable in them." Dr. Derbyshire's methods of doing business are practically identical with those of Dr. Day, and her diagnoses are just as fraudulent and worthless. In a later article, we may give some space to the Derbyshire concern and also to the Kidd branch of Griffin's quackery.

DR. BERTHA C. DAY COMPANY

Dr. Bertha C. Day is the stool-pigeon for Wm. M. Griffin in operating a mail-order medical treatment for the "diseases of women." The Bertha C. Day concern advertises in those cheap and nasty magazines that are the sheet-anchor of the advertising medical faker; it also has an occasional advertisement in the less particular newspapers (Fig. 1). Bertha C. Day advertises that she is "a woman—a wife—a mother—a successful physician—a specialist on diseases of women." She puts great stress on her "long and varied experience." In a booklet entitled, "Diseases of Women and The Home Medical Guide" (Fig. 2), which she sends to those who answer the advertisement and which she claims to have written, we read:

> "Her *vast experience* as a physician is only one of the qualifications she possesses . . ."
>
> "Her training and *vast experience* as a physician enables her to do more for suffering women than any woman can who is not a physician . . ."
>
> "During *several years* of active life *as a general practitioner* she acquired a vast amount of valuable experience that very few ever possess . . ." [Italics ours.—Ed.]

These quotations—from a book written in 1909—naturally give the reader the impression that Dr. Bertha C. Day has been in practice for several years. As a matter of fact, Dr. Day graduated from the Detroit Homeopathic College in 1907 and was licensed to practice in 1908! This would indicate that however "varied" her experience may have been, it could scarcely, with truth, be called long. As the "Bertha C. Day Company" was chartered in 1908—the year that Bertha C. Day received her license to practice medicine—her "vast experience" has evidently been confined to treating people she has never seen, by means of tablets bought in million lots and prescribed on diagnoses that are both worthless and fraudulent.

THE METHODS EMPLOYED

An individual, whom we may call Mrs. X, seeing one of Bertha C. Day's advertisements, wrote for particulars about the methods of "treatment." By return mail she received a form letter in which the date and her name were filled in by means of a typewriter. The letter stated among other things:

> "Before preparing the treatment for you, however, it will be necessary for me to have a more thorough understanding of your case. I am, therefore, inclosing herewith a Symptom Blank, which I will be pleased to have you fill out and return to me."

The "Symptom Blank" consisted of a number of questions to be answered. There was also a list of diseases and symptoms, and the patient was instructed to "draw a line under any of the following diseases or symptoms you have." Accordingly, Mrs. X underscored the following:

"LEUCORRHEA"
"CONSTIPATION"
"PAINFUL PERIODS"
"FEMALE TROUBLE"

On sending this in to Dr. Day, form letter No. 2 came back containing among many other things, the statement:

> "A careful diagnosis of your case shows you have *Vaginitis, Constipation, Painful Menstruation* and *Female Weakness.*"

The words we have put in italics had been filled in by means of a typewriter, having the same style and size of type and the same color ink as that used in printing the rest of the letter. How much skill and "vast experience" was necessary to make such a diagnosis from the symptom blank? The facts are, the "careful diagnosis" showed that Mrs. X was suffering from the very complaints that she had told Dr. Day she was suffering from. In other words, Mrs. X diagnosed her own case. In the same form letter Mrs. X was told:

> "I have mailed you a copy of my book, 'Diseases of Women and Home Medical Guide.' Be sure to read the description of your condition on Pages *86, 32, 58, 27 and 25-47.*"

THE FREE AND SPECIAL TREATMENTS

Here again, the figures we are italicizing were the only part of the paragraph that had been typewritten; the rest was printed. The same mail that brought this letter also brought a "free trial treatment," supposed to last three days and also a "special treatment" for which she had not asked. Mrs. X was told:

"Your case seems to be of long standing and you really should have the complete Course of Treatment at once, if you are to be completely cured. As I want to do everything possible for you, I have prepared a 'Special' course of treatment for you and am sending it, postage paid, in the same package with the free remedies."

The free treatment consisted of:

Six purple, triangular, coated tablets marked "C."
Three red, triangular, coated tablets marked "D."
Three pink, circular, coated tablets marked "45."
Two large, white, oval, uncoated tablets for vaginal use marked "31."
One large, soft, cylindrical, vaginal suppository marked "30."

The "special treatment" received by Mrs. X consisted of six different kinds of tablets each labeled with a letter or number, prefixed with the words "Dr. Day's Private Formula:"

"No. A:" fifteen red, triangular, coated tablets.
"No. B:" fifteen lavender-colored, triangular, coated tablets.
"No. 45:" fifteen pink, circular, coated tablets.
"No. 58:" fifteen brown, circular, uncoated tablets.
"No. 14:" thirty-two, lavender-colored, circular, coated tablets.
"No. 31:" fifteen large, white, oval, uncoated tablets for vaginal use.

The probable composition of these variegated and multi-shaped tablets was determined in the following manner: In *addition to her usual advertisements*, Dr. Bertha C. Day also advertises that she will send "free prescriptions" to those who will fill out and send her the blanks that accompany such advertisements. One such blank was filled out and sent in by another person giving the same symptoms as those Mrs. X was supposed to be suffering from. *In reply*, there were received a letter and five printed prescriptions (see also Fig. 3); each of these was numbered or lettered the same as the tablets sent to Mrs. X, except that there was no prescription for "No. 31"—the tablets for vaginal use. Incidentally, at the same time that the "*free prescription*" was received the express company brought a package of tablets *from Dr. Day, C.O.D., $2.50*. But of this more later. According to these prescriptions, the tablets "A," "B," "45," "58" and "14" have the following composition:

Fig. 1.—Photographic reproduction (much reduced) of a typical advertisement of Dr. Bertha C. Day. Note the coupon in the lower right-hand corner by means of which Dr. Day pretends to be able to diagnose a woman's ailments. The size of the original advertisement, which appeared in *The Gentlewoman*, was about 10 by 14 inches.

"A"

℞.

Ext. Gentian	7½	grains.
Strychnin Sulphate	¼	grain.
Ext. Quassia	7½	grains.
Bicarb. Soda	45	grains.

"B"

℞.

Strychnin Sulphate	¼	grain.
Ext. Rhubarb	15	grains.
Ext. Cascara Sagrada	15	grains.
Bicarb. Soda	30	grains.

"45"

℞.

Cascarin	4	grains.
Aloin	4	grains.
Podophyllin	2½	grains.
Ext. Belladonna Leaves	2	grains.
Strychnin Sulphate	¼	grain.
Oleoresin of Ginger	2	grains.

"58"

℞.

Strychnin Sulphate	1/6	grain.
Powdered Ipecac	1/2	grain.
Oleoresin of capsicum	1/12	grain.

"14"

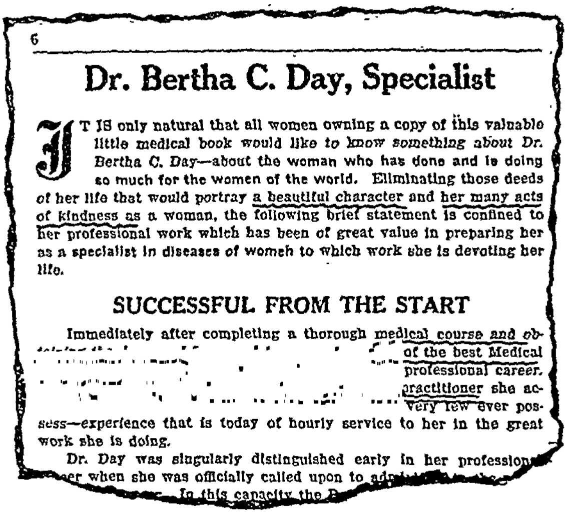
℞.

Ext. Black Haw	30	grains.
Ext. Jamaica Dogwood	15	grains.
Powdered Ginger	½	grain.
Fluidextract of Pulsatilla	30	m.
Fluidextract Gelsemium	3½	m.

As has been said there was no prescription for "No. 31," but printed on the box that contained these vaginal tablets was the statement:

"Each contains 3 grains of acetanilid and ½ grain (¼ gr.?) powdered opium."

As this information was put on the box, apparently as an afterthought, by means of a rubber stamp, the lettering was so illegible that it was impossible to say whether the tablets were stated to contain ¼ or ½ grain *of opium*.



6

Dr. Bertha C. Day, Specialist

IT IS only natural that all women owning a copy of this valuable little medical book *would like to know something about Dr. Bertha C. Day*—about the woman who has done and is doing so much for the women of the world. Eliminating those deeds of her life that would portray a beautiful character and her many acts of kindness as a woman, the following brief statement is confined to her professional work which has been of great value in preparing her as a specialist in diseases of women to which work she is devoting her life.

SUCCESSFUL FROM THE START

Immediately after completing a thorough medical course and ob- [illegible] of the best Medical [illegible] professional career. [illegible] practitioner she ac- [illegible] very few ever possess—experience that is today of hourly service to her in the great work she is doing.

Dr. Day was singularly distinguished early in her profession[illegible] [illegible]er when she was officially called upon to ad[illegible] [illegible] In this capacity the [illegible]

Fig. 2.—Photographic reproduction (reduced) of part of a page from the booklet, "Diseases of Women," "*written and published* by Dr. Bertha C. Day." Note the modesty of Dr. Day's self-delineation: "beautiful character," "acts of kindness," etc. Note, also, reference to "one of the best medical colleges in America." In the Carnegie report on *medical education* the following statement is made regarding this college: "*Laboratory Facilities:* These are wretched . . . The teaching rooms are bare except for the chairs and tables; the building is poorly kept." The same college is also grouped by *the Council on Medical Education* of the American Medical Association in "Class C," *that is*, "*Medical colleges* which would require a complete reorganization to make them acceptable." Note, too, the reference to the "several years of active life as a general practitioner." These words were written in 1909; Dr. Day became legally entitled to practice medicine in October, 1908! Years of experience, indeed!

With the letter, notifying Mrs. X that the "special" and "free treatment" were being sent, was a page of directions for taking the medicines. The directions were printed in imitation typewriting and the "private formula" letters "A," "B," "C," "D," etc., have been filled in by means of a typewriter. The designation "No. 45," was printed instead of typewritten so that it is probable that whatever ails the patient, "Dr. Day's Private Formula No. 45" is always sent.

THE SLIDING SCALE OF PRICES

The price Mrs. X was asked for the "special treatment," was $2.00 and, as she did not send the money, Dr. Day, consistently following the methods of mail-order fakers, sent a series of follow-up letters. The general object of these letters is, apparently, gradually to lessen the amount asked for the "special treatment." It was evident, however, from some of the letters sent to Mrs. X that the mailing clerks who send out these heart-to-heart "personal" talks from Dr. Day, are careless in selecting the right form-letter. In Mrs. X's case the first price asked, as has been already stated, was $2.00. In Dr. Day's third letter she says:

> "As I made you a reduced price of $3.00, I hope you can remit the amount soon."

Evidently the mailing force at Dr. Day's establishment got this $2.00 patient confused with a $3.00 patient. Form letter No. 4 is one of those frankly, confidential epistles that the mail-order fraternity get printed by the hundred-thousand and sign with a rubber stamp. The amount of the bill is not mentioned in this letter, it is merely an earnest request to send the money. The next form letter, No. 5, commences:

> "I am busy with my patients this morning, but I feel I must take time to write you a note . . ."

Then follows the usual farrago of sentimental nonsense about being " a woman and a mother," and having a "sympathetic feeling" for the patient and Dr. Day once more urges Mrs. X to send the money.

Fig. 3.—Photographic reproduction (reduced) of three prescriptions printed in imitation typewriting and sent by Dr. Bertha C. Day to a person supposed to be suffering from obesity. Notice that prescription No. 8 directs that the drugs be compounded *in the form of a suppository*, yet the directions sent by Dr. Day state that they must be "prepared *in tablet form*," one tablet to be taken before breakfast and one after dinner!

> "Something must be done at once—we must come to an understanding. Your health is being neglected . . ."

Thus commences form letter No. 6, and something *is* done: Dr. Bertha comes down to $1.00.

> "Send me a $1.00 bill and the special fifteen-day treatment is yours."

This $1.00, the patient is told, "will pay in full for the $3.00 course . . . "—which was originally offered in the first letter for $2.00. As a slight reward for giving the "cut rate" for her tablets of many colors Dr. Day asks that the patient will send in a number of names and addresses of "others who need treatment." Presumably, this is a cheaper way of getting a mailing list, than by purchasing the names of a letter broker.

According to the opening sentence in form-letter No. 7:

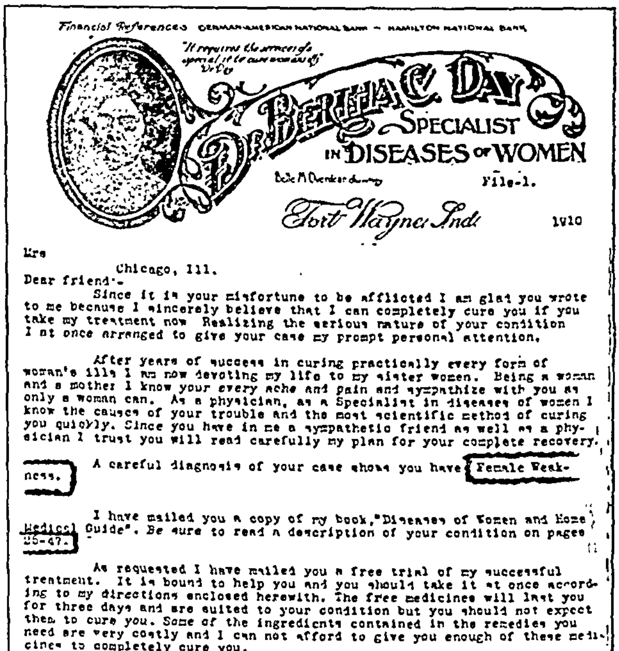
> "This is the MOST IMPORTANT letter I have ever written to you . . . NOW LISTEN: if you can't see your way clear to accept the Special Treatment on the low terms I quoted you, simply send $1.50 and start using the remedies."

From this series of follow-up letters, which is but one of several series of a similar nature that we have on file, it will be seen that the price for this special treatment starts at $2.00, rises to $3.00, falls to $1.00 and closes at $1.50. To those who are familiar with the "ways that are dark and tricks that are vain" of mail-order medical concerns, this fluctuation in the market price of the "special treatment" merely means that the form-letters have been carelessly mailed. To the unsuspecting females who think that these letters are confidential personal communications to them, and to them alone, the variations in price must be disconcerting.

TWO OTHER DIAGNOSES

The following brief note was sent by another individual, whom we may call Mrs. Y, to Dr. Bertha C. Day:

> "Dear Doctor:—Will you please write and tell me about your cure for female trouble?"



Financial References GERMAN-AMERICAN NATIONAL BANK — HAMILTON NATIONAL BANK

Dr. Bertha C. Day
Specialist in Diseases of Women

File-1.

Fort Wayne Ind. 1910

Mrs

Chicago, Ill.

Dear friend:-

Since it is your misfortune to be afflicted I am glad you wrote to me because I sincerely believe that I can completely cure you if you take my treatment now Realizing the serious nature of your condition I at once arranged to give your case my prompt personal attention.

After years of success in curing practically every form of woman's ills I am now devoting my life to my sister women. Being a woman and a mother I know your every ache and pain and sympathize with you as only a woman can. As a physician, as a Specialist in diseases of women I know the causes of your trouble and the most scientific method of curing you quickly. Since you have in me a sympathetic friend as well as a physician I trust you will read carefully my plan for your complete recovery.

A careful diagnosis of your case shows you have Female Weakness.

I have mailed you a copy of my book,"Diseases of Women and Home Medical Guide". Be sure to read a description of your condition on pages 25-47.

As requested I have mailed you a free trial of my successful treatment. It is bound to help you and you should take it at once according to my directions enclosed herewith. The free medicines will last you for three days and are suited to your condition but you should not expect them to cure you. Some of the ingredients contained in the remedies you need are very costly and I can not afford to give you enough of these medicines to completely cure you.

Your case seems to be of long standing and you really should have a Complete Course of Treatment at once if you are to be completely cured. As I want to do everything possible for you I have prepared a Special Course of treatment for you and am sending it postage paid, in the same package with the free remedies.

Please understand that the free remedies are yours to take at once without charge or obligation, but if you use the Special Treatment I shall expect you to send me $3 for it. You need not feel under obligation to me to accept the Special Course but I know it is just what you need and need NOW, so I feel sure your good judgment will cause you to accept it at your earliest convenience. By sending now I save you some time and

Fig. 4.—Photographic reproduction (reduced) of one page of a two-page letter sent by Dr. Day in answer to a brief note, asking for particulars about her "cure for female trouble." Practically all of this letter was printed; the name and address and "diagnosis" only, being filled in by means of a typewriter. The words and figures in paragraphs three and four, around which heavy lines have been drawn, were the words that were filled in on the typewriter.

This is all that was written, yet the information was sufficient for the diagnostic powers of Dr. Day, who wrote back:

> "A careful diagnosis of your case shows you have *Female Weakness*." (See Fig. 4.)

Here again the words we have italicized were filled in by means of a typewriter; the rest of the letter was printed in imitation typewriting. The regulation "free treatment" was also sent to Mrs. Y, together with a "special treatment." The price asked for the "special treatment" in this case was $3.00. It seems, then, that when Dr. Day puts up a "special treatment" for "female weakness, vaginitis, constipation and painful menstruation" she can do it for $2.00; when, however, she makes a "special treatment" for "female weakness" alone, it costs $3.00. The principle on which this business is run, apparently, is that the less you have the matter with you, the more it costs to cure you.

The series of follow-up letters sent to Mrs. Y also shows as much lack of care in picking out the correct form-letter as did the series sent to Mrs. X. As Mrs. Y did not send the $3.00 asked for, form letter No. 2 came in due time, stating:

> "As I made you a reduced price of $2.00, I hope you can remit the amount soon."

Here, apparently, is the form-letter that should have been sent to Mrs. X, who really was offered the treatment in the first letter for $2.00.

A DIAGNOSIS OF RHEUMATISM

Still another letter was written as follows:

> "Dear Doctor:—Will you please write and tell me if you can do anything for rheumatism?"

By return mail came the stock diagnosis letter with the statement:

> "A careful diagnosis of your case shows you have *rheumatism, and associated conditions.*"

A subsequent mail brought the inevitable "free treatment" and the accompanying "special treatment." Here again the carelessness of the detail work done in the Bertha C. Day office was apparent. In addition to the box of variegated pills that composed the "special treatment," there was sent a collapsible metal tube filled with an ointment smelling strongly of phenol (carbolic acid). This was marked "Dr. Day's Private Formula No. 26." The sheet of directions made no reference to Formula No. 26, but it did contain a statement regarding a "Formula No. 48." No preparation having the latter number was sent. The directions pasted on the tube of ointment read:

> "Unscrew cap of tube, then screw nozzle in its place. Each evening wash the parts with soap and water. Insert nozzle into the rectum, forcing a small portion of the ointment out of the tube by pressing the lower end."

No nozzle accompanied the package and had it done so, it would be a little difficult to see how a person was going to be cured of rheumatism by injecting a carbolic acid ointment into the rectum. The facts were, of course, that the mailing force at Griffin's establishment had confused a "treatment" for "piles" with a "treatment" for "rheumatism." It is interesting to speculate what may have happened to the poor sufferer from piles who received the rheumatism treatment with directions to inject it into the rectum.

ANOTHER DIAGNOSIS AND A MODIFIED METHOD OF TREATMENT

As has already been shown, Mr. Griffin sometimes modifies his method of doing business. An advertisement appears in which Dr. Day offers to send "Priceless Prescriptions for the Cure of Female Diseases Free to Any Woman." Part of the advertisement is a coupon (Fig. 1) containing a list of diseases and symptoms and the patient is asked:

> "Make a cross (X) in front of your trouble. Two crosses (XX) in front of the one from which you suffer most."

One of these coupons was sent in to the company with the word "obesity" marked. By return mail came one of Dr. Day's famous diagnosis letters, stating among other things:

> "A careful diagnosis of your case shows that you have *Obesity and associated conditions.*"

"Obesity and associated conditions" were the four words in the whole letter that were filled in by means of a typewriter; the balance of the letter, with the exception of the name and address of the patient, was printed, in the usual imitation of typewriting. With this letter three prescriptions were sent. These prescriptions, printed in imitation typewriting on prescription blanks headed, "Private Office of Dr. Bertha C. Day," were an atrocious mixture of incorrect Latin and poor English, as may be seen by the photographic reproductions (Fig. 3).

After reading all that accompanied the prescriptions the cloven hoof became evident:

> "There are so many reasons why I am afraid you will not be able to get these prescriptions filled properly and at the right price, that I have decided . . . to supply you with the medicines you need direct from my office . . .
>
> "In order that you may begin treatment at once, to save you the trouble of ordering from me or of trying to have the various prescriptions filled, I have decided to send you the Special Treatment you need by Express, prepaid. I have paid the express charges so that all you have to pay the Express Co. is the reduced price of $2.50 which I am making to you."

Dr. Day then says that the patient is under no obligation to accept the package, but, as a physician, she feels it her duty to send the medicines at once. Furthermore, the $2.50 "also entitles you to my professional advice."

The victim, in this case, did not bite and received the usual series of follow-up letters urging her to take the package from the express company and to remit the money. Finally the patient wrote that she had not taken the packages from the express office because she could get the prescriptions filled at the drug store so much cheaper. Back came a letter, stating that this course was "perfectly satisfactory" to Dr. Day. How very unsatisfactory it was to Mr. Griffin's company is evident from the following paragraph:

> "I wish to warn you against trusting this work to a careless and unprincipled druggist who might substitute drugs similar but inferior to those called for in the prescription."

Further:

> "Be sure that all the medicines to be used internally *are prepared in tablet form.* This is very important." [Italics ours.—Ed.]

Not content with vilifying the druggist and accusing him of substitution and lack of principle, those fakers are bound to make the patient dissatisfied with the druggist's work however honestly done. The main prescription of the three given above calls for desiccated thyroid and phytolacca berry compounded *in the form of a suppository.* Yet these humbugs have the effrontery to insist that the patient be sure that the medicine "be prepared *in tablet form.*"

CONCLUSION

So much for the methods of the Bertha C. Day mail-order medical fake. The dishonesty of the claims, the fraudulence of the methods and the general way in which the business is conducted, are all typical of those concerns which make a business of capitalizing suffering and defrauding the sick. Could that vast army of women whose gullibility permits these frauds to flourish but learn the hollow pretense on which such businesses are founded, the mail-order medical fake would cease to exist.

There are doubtless hundreds of thousands of men and women who really believe that the skilfully printed letters sent to them by mail-order quacks are special, personal and private communications. They doubtless believe too, that the "diagnoses" which these fakers furnish have actual value. They probably believe, also, that the pills of many shapes and colors that are sent out by these concerns have some peculiar potency and value not possessed by the drugs prescribed by the family physician. They must believe all these things or the mail-order medical business would not be profitable.

Did the victims of these sharks really know that the letters are printed by the hundreds of thousands and are "filled in" by girls who have no more medical knowledge than the average school-girl would have; did they know that the "diagnoses" are always worthless and sometimes dangerous; did they know that the medicines furnished are often the cheapest of cheap drugs bought in enormous quantities from the least reputable of drug houses; did they know, too, that after they had been bled to the point where they are unwilling to part with any more money, their letters would be sold to other vampires in the same business—did they know all these things, the firms that pretend to cure diseases about which they know nothing, with drugs about which they know less, in patients they have never seen, would soon be forced into some more respectable, if less profitable, line of business.

An Unscientific Prescription

To the Editor:—There have recently been published in the department of The Journal devoted to the "Propaganda for Reform," some excellent examples of shot-gun prescriptions, accompanied by terse and appropriate criticisms.

Below, I offer an exact copy of a prescription which a patient was given by a physician practicing at a mountain resort where she visited last summer. She affirmed that it did her much good, showed it to me for its educational value, would not part with it for anything, but permitted me to take a copy. I might add that her complaint was of a slight indigestion, and that besides these wonderful powders, she was ordered a daily enema consisting of 1 dram of turpentine in 2 quarts of water, and a diet consisting of milk and weak tea to be continued two weeks. She of course credited the powders with being the curative agent.

I offer this in the hope that it may serve as a text for some further remarks on "prescription writing."

M. Schulman, New York.

Comment: The above prescription is not one to be recommended because it is an attempt to meet too many indications in the same formula. It is evident that the writer wished to give a tonic, a laxative, an intestinal antiseptic and a digestive agent. In order to meet all possible emergencies, he has introduced two digestives, one active in acid and the other in alkali. Of course, only one of these can be efficient, and as clinical experience shows that pepsin is secreted whenever acid is present, the pepsin in the prescription is superfluous. Furthermore, the prescription is an example of polypharmacy, and is to be criticized on this account, although it is not so bad in this regard. Such a combination would have a tendency to correct hyperchlorhydria, flatulence and constipation, and possibly it was given for such a purpose.

As we have frequently mentioned the desirability of making the language of a prescription correct and consistent, avoiding a hodgepodge of Latin and English, we need only add that the prescription given above has not been edited.

Correspondence

Physicians—The Supply and Demand

To the Editor:—We read now and then of the oversupply of medical practitioners in Great Britain, France, Germany and the United States. Is not this condition due to the congestion of favored localities and not to the demands of the world?

The relation of the medical profession to the movements for the spread of civilization and the development of backward regions of the earth has never been properly realized. There are as yet very few physicians appointed by civilized governments as functionaries, consuls and consular agents, but wherever they have been given official positions they have made good in an exemplary manner.

Countries imperfectly developed would benefit greatly by appointment of men with a medical training as officials in their remote districts. These men would enter fully into the life of the people, carry out sanitary regulations, keep accurate vital statistics, and would furnish reports on climates, soils, ethnology, geology and biology that would be of value to the government employing them and to the whole world.

Men of no other class are so well adapted for this work; their professional services and humane principles would insure the confidence of those placed under their supervision.

China affords an extensive field for physicians, and the great success of medical missionaries there and in India and Turkey shows that the harvest is plentiful even if the proper laborers be few. The United States furnishes a wide scope for medical men, not only in Alaska and the island possessions, but also as consular agents in South and Central America, in the Balkans, Asiatic Turkey, Persia and other unadvanced countries. The great success of Dr. Grenfell in Labrador shows what even one medical man can do, and what no one but a medical man could have accomplished.

William P. Whery, M.D., Fort Wayne, Ind.

What About the Medical Profession in This Country?

To the Editor:—Mr. Pritchett's article in The Journal, February 25, on criticisms of the Flexner report recalls some reflections I made at the time of reading the report. On pages 13 and 14 of the report the question of ratio of physicians to population in Europe and this country is discussed and the conclusions are based on the supposition that the same ratio of physicians to population would be sufficient for this country. Mr. Flexner's reasoning may be logical but I submit that his major premise, to wit, that this country can be served by the same ratio of physicians to population here as in Europe is wide of the mark.

Medical attendance in European countries is a luxury, usually possible only to the better classes, at least until very recently when, for economic reasons, the state has brought it within reach of the workers in large industries to keep the latter going. The barbarous system of midwifery is still in existence among all but the highest strata of society—and the paupers at maternities. Just now, the Russian sanitarians are finding out that puerperal sepsis is as prevalent in midwife practice outside of institutions as before antiseptic days. It is beneath the dignity of a physician of continental Europe to attend an ordinary case of confinement, and it is beyond the ability of the ordinary industrial family to pay for such service.

In this country, conditions are entirely different. Our sense of humanity dictates that, in any case of confinement needing any attention beyond the good offices of the neighbor or relative female friend, the woman should have the assistance of a physician. Every American, or Americanized parturient demands it—it is a humane necessity to our women, a luxury to their European sisters. So far all industrial classes of our population outside of the slum districts and half civilized foreign quarters have been able to get this service and pay for it. And so with ordinary cases of sickness; here the masses send for the physician and are able to pay him, while among the masses in Europe the physician is not called except in extreme emergencies and the patient usually recovers or dies and no more is thought of it; except that it is an act of God.

I am not overstating it when I say that our higher standard of living demands at least twice as large a ratio of physicians to population as does Europe. The public is now demanding and *paying for the services* of twice as large a ratio of physicians. I am now speaking of conditions as I know them to exist in the northwest. There is no overcrowding of physicians in the northwest outside of the large cities; in fact, there are any number of good openings for men who are competent to do general practice and willing to drive out 10 or 15 miles in the country at night, any time of the year, for a reasonable fee. Now, understand, I say competent and willing to do general practice in small towns and rural districts.

I believe Mr. Flexner mentions one Johns Hopkins' graduate who settled in a rural district, and I know of a few others who could write B.A., M.A. and M.D. after their names who, have settled in rural districts, but these are exceptions that prove the rule that the man who has the time and the money to spend ten of the best years of his life to acquire a medical education does not settle in small towns to engage in general practice. The demand now existing for a competent general practitioner cannot be filled from the high-class medical graduate—for obvious reasons, psychologic, social and commercial.

Mr. Flexner has done a valuable service to the medical profession of this country by fearlessly spotting the commercial diploma mills. But his constructive medical education program will not meet the needs of this country. We have, for instance, one good medical school in Minnesota, but the records of admission to practice here show that it is wholly inadequate to the needs of the state. Happily, Chicago is near by and can help us out, and our legislature has opened the door to the osteopath to supply any possible shortage of doctors. Mr. Flexner's Prussian idea of one doctor to every 2,000 population does not work in this country where a popular legislature and not the Kaiser's Kultus-Minister has the say in this matter.

Of late years the medical education theorist—Flexner is the type—has been raising the requirement for medical licensure to correspond with intramural conceptions. On the other hand, the public through the legislatures has been creating osteopaths and the like, to supply themselves with medical service outside of the regular profession; these two processes go on *pari passu*. The higher the professional requirement beyond a certain point—already passed in some states—the wider the doors for irregular "paths" and quackery are opened. It takes no prophet to see that if the medical theorist keeps forcing his hobby we shall soon have several legal medical professions in this country. How would it be if the general practitioner, the one who knows the needs of the people he is serving, were given a hearing on this question?

CHRISTIAN JOHNSON, M.D., Willmar, Minn.

[COMMENT:—Our correspondent apparently misunderstands the argument. Mr. Flexner did not intend to imply that the Prussian ratio was applicable to this country. In the report referred to, at the bottom of page 16 and the top of page 17, it is distinctly stated: "We are not now arguing that a ratio of 1 :1500 is correct . . . Our contention is simply that, starting with our present overcrowded condition, production henceforth at the ratio of one physician to every *increase* of 1,500 in population will prevent a shortage, for the next generation at least." And in order to avoid any possible misunderstanding, the word "increase" in the report is in italics. As to the reluctance of well-trained physicians to locate in small towns, the same is apparently true of graduates of low grade colleges. Regarding such localities, Mr. Flexner says, (p. 15) "A century of reckless overproduction of cheap doctors . . . has not forced doctors into these hopeless spots." Furthermore, Mr. Flexner makes the suggestion on page 16 that, as a last resort, possibly the best way to get good men to go to unpromising locations is for "the several states to salary district physicians in thinly settled or remote regions."—ED.]

The Plague in China

[Dr. Hiram Woods of Baltimore sends the following extract from a letter from a missionary in Paoting-Fu, China, who is supported by the First Presbyterian church of Baltimore.]

Feb. 5, 1911: We are in the midst of a siege of plague, This plague started in Harbin, Manchuria, late in November, or early in December, last year. The Chinese were very slow to take hold of it, and so it got a big start. Then other nations (Russia and Japan) said something must be done or they must interfere to stop its ravages. China, fearing lest these nations should get a greater foothold than they now have, asked for volunteers in our Union Medical College in Peking. Four men came forward to help. The Chinese also used the medical staff and the students in their two medical colleges in Tientsin. A professor from one of these colleges, Dr. Mesny, a Frenchman, went up, took plague and died, as did also one of his students.

The Chinese have been doing what they can to stop it in the original focus and in other places whence it has spread, but up to the present very little progress has been made in checking the epidemic. The medical missionary force has taken a leading part in the work everywhere, and one physician has died in Mukden, Dr. Johnson of the Scotch Presbyterian Mission. He seems to have taken every precaution, wore a respirator and covered himself well. He was a young man, very careful and conscientious, but his work of disinfection and segregation took him into crowded places.

This epidemic is not the bubonic form of plague but the pneumonic. It has been found that the greatest danger is air-borne infection; respirators are very necessary, therefore, when one comes in contact with infected individuals. Rats have been examined and no infection found in them. The government was very slow in stopping the trains, and the disease was carried into China proper, and now it is present at many places in this province and in Shantung. Many workmen from these two provinces work in Manchuria, and when the plague broke out there they left for home. If the government had stopped the train service early, it could have prevented spread of the disease south of the government wall.

An individual only lives about two or three days, at most six, after taking the disease. There has not been a recovery in an authenticated case. A family came from Harbin to their home about 12 miles from here, and after arriving at home almost all the members were taken ill and died; other families were then taken ill. In all thirty-six persons have died in that small village. Two army physicians have gone down there to see what can be done in the way of isolating the families who have had plague and burning the houses and contents.

The officials have asked me to take charge of the sanitation of the city here and we have organized a plague prevention league. We meet every day and discuss measures by which we can prevent the plague from entering the city. Up to the present, we have had no authentic cases. Dr. Dilley of our mission in Peking, has kindly come to my assistance. He has taken charge of the hospital which we have prepared hurriedly for "suspects" and also takes the examinations of trains. We have been examining all passengers on the south-bound trains in order, if possible, not to allow the disease to spread further. We have heard of another place, 35 miles south of this city, where thirty persons have died in four villages. These villages will be examined and restrictive measures put on the migration of people. We are trying to instruct the entire police force here by daily lectures, lasting for an hour, so that if the disease should break out we will have some intelligent men to cope with it, who will know how to take a man to the hospital or a corpse to the cemetery without infecting themselves; and another batch to follow them in disinfecting houses. We are having all inns inspected twice every day so as to discover sick persons early and get them off to the "suspects" camp. We have three native doctors to help us; we ought to have fifty to do the work that should be done here to stop the ravages of plague if it gets into this city.

I have turned over my entire hospital force to the government service in this time of need, and I hope that this work with the officials may give us the opportunity to show them that we are not simply a cranky religious sect, but men who love our fellow men and serve our God, who is worthy of being their God and Savior.

I do not know when we will ever be able to do medical work, that is, to open our hospital here. Of course, if we got plague into it, we would be in a bad way, for it is said that burning is the only safe way to disinfect a building. I am afraid North China is in for a serious time for many years, and that our mission work will suffer much for this. It will be almost impossible to go to the country to work, as one would be constantly running into plague, and if this virulent form persists it means sure death to any one who takes the disease; as I have said, no one recovers. One can hardly dare to imagine the future of poor China for the next few months. The heat may stop the disease in a few months or so, or it may appear in bubonic form, when the flea season comes, and kill half the population; no one can tell. I wish America would show her friendship for this needy land now, and send out fifty sanitary engineers to cope with this awful pest, and thus save millions of lives that are worth saving. Can't you stir up President Taft or some big man to do this?"

CHARLES LEWIS, M.D., Paoting-Fu, China.
Physician in Charge, The Taylor Memorial Hospital.

The Secret Commission Evil

To the Editor:—I have read with great interest the article and editorial on "The Secret Commission Evil," in THE JOURNAL, March 11. I am glad to see the Association take such a position, as here in Kansas, commission-giving is practiced to an appalling extent. I have been offered a commission from the owner of a private hospital on the hospital fees of any patients I might send. A dentist friend of mine tells me he has been approached by a physician with a suggestion that he give a commission on patients that he might send to him, and that this was not an uncommon practice. In Topeka, the ruling commission is 40 per cent, but one man has advanced it to 75 per cent.

In the last session of the legislature, the medical department of the university was interested in some bills which were introduced by a physician. A good friend of the institution told me that I had made a mistake in having a physician introduce any bills, as it always created a suspicion of graft and crookedness, and the members were very slow to accept it on that account.

I hardly know whether we can control this evil in Kansas or not. I have on file a letter, in reference to a statement that I made in regard to this thing, from a general practitioner which reads as follows: "I am surprised at the enclosed clipping. How many of the best surgeons in the state can you name who will not 'split the bill?' I do not know a surgeon in the state who would hog the whole thing."

I am afraid that this represents the feeling of a large percentage of physicians over the state. However, any help that you can give us in combating this evil will be greatly appreciated by at least some of us.

Mervin T. Sudler, M.D., Lawrence, Kans.

Queries and Minor Notes

Anonymous Communications will not be noticed. Every letter must contain the writer's name and address, but these will be omitted, on request.

JOURNALS ON SEXUAL PHENOMENA

To the Editor:—Please publish in your Department of Queries and Minor Notes the names of journals published in English or other language devoted to the study of sexual phenomena in any of their scientific aspects.

Joseph H. Toomey, M.D., Chelsea, Mass.

Answer.—So far as we know, the only journals devoted specifically to sexual phenomenon which are still being published are the following:

Die neue Generation, monthly official organ of the Bund für Mutterschutz, edited by Helene Stöcker, Berlin, Germany.

Sexual-Probleme, monthly, published by J. D. Sauerlanders, Frankfort on the Main, Germany.

Several others (chiefly German) have been discontinued. The transactions of several societies interested in the subject are published periodically. The transactions of the third congress of the Deutsche Gesellschaft zur Bekämpfung der Geschlechtskrankheiten are published under the title of "Sexualpädagogik."

SANITATION AND CIVILIZATION

To the Editor:—What evidence have we that our sanitary and other measures (in the broadest sense) are of ultimate value as opposed to the fatalistic neglect of such measures among Oriental nations? For example, if we reduce the number of deaths from tuberculosis, or from all infectious diseases, may not other diseases —existing or to be developed—restore a balance in this phase of evolution?

I have in mind a comparison, in a broad way, of the span of life and the mortality (per 100,000) among savage and civilized races through a period of centuries rather than years, as well as the span of life and mortality of civilized races compared with those of former times.

I have in mind also the immunity gradually acquired to diseases such as syphilis and measles (as in South Sea Islands), where such devastation occurred. I am thinking also of the law "a rise in birth-rate entails a rise in death-rate, and *vice versa*," and in a larger way "of life on a basis subsistence," according to Malthus.

H. B. Forbes, Ogden, Utah.

Answer.—A full discussion of the subject proposed by our correspondent would consume more space than would be profitable for The Journal to devote to it. The data as to mortality in uncivilized or partly civilized countries are not sufficiently accurate to afford a safe basis for comparison. Of course, the early infant mortality in uncivilized countries tends to the survival of strong individuals as the weak die out. This is, however, a loss, for many such individuals who are weakly in childhood grow up under favorable circumstances to become vigorous adults of great value to the state. It is amply demonstrated that civilized communities tend to increase in population to a greater extent than savage tribes, and this is largely due to hygienic progress and sanitary laws. The fact that the Indians in this country are dying out shows the operation of insanitary conditions in spite of long habituation which ought to have brought immunity and prolonged life if the theory under discussion were true. See also abstract of Prinzing's paper on this subject in the Berlin Letter, March 4, 1911, p. 682.

ETIQUETTE OF CALLS BY NEWCOMER

To the Editor:—Please give the ethics of calling for doctors locating in new territory. Should the newcomer call first on resident practitioners? Is the old custom reversed?

E. R. Barney, Wattsburg, Pa.

Answer.—Several years ago The Journal answered this question, but because of the time that has elapsed, we repeat: "It is an accepted custom for young physicians and newcomers to call on the older physicians and those of longer residence in the locality. It is a mark of courtesy and respect due from one locating in a new place. He thus announces his arrival and his desire to be recognized in professional circles and friendships." Some correspondence followed this "answer," which made it evident that this custom is sometimes confused with that which governs social relations when a family moves into a new locality.

THYROID IN HEMOPHILIA

To the Editor:—In reply to the communication of Dr. N. C. Miller in The Journal of March 18, I would like to recommend thyroid extract for his cases of hemophilia. In the *Annals of Surgery*, May, 1907, I published an account of a case cured by this drug after I had exhausted all the ordinary methods of treatment. I always give thyroid extract in cases in which I suspect a tendency to bleed or in which any such tendency is shown. Also, in cases of disturbed metabolism when the tissues are indolent thyroid gives good results.

J. Torrance Rugh, Philadelphia.

REMOVAL OF ADHESIVE PLASTER

To the Editor:—A little lard or hydrated wool fat (lanolin) rubbed into adhesive plaster will loosen it in a very few minutes and is much less unpleasant than gasoline or any other substance I have seen recommended in the recent discussion of this subject [Jan. 28, Feb. 25, and March 4, 1911]. Also, it can usually be found in every house.

H. R. Coston, Birmingham, Ala.

The Public Service

Medical Department, U. S. Army

Changes for the week ended March 25, 1911.

Love, Joseph W., M.R.C., March 17, ordered to proceed from Fort Preble, Maine, to Fort Banks, Mass., for duty at that post.

Newton, Ralph W., March 17, ordered to proceed, about April 15, 1911, from Fort Revere, Mass., to Fort Andrews, Mass., for duty at that post.

Brooke, John D., and Hull, Alva R., cont. surgeons, March 11, entered into for duty as cont. surgeons, U. S Army.

Eyster, George L., March 20, entered into for duty as cont. surgeon, U. S. Army.

The following named officers of the M. R. C. will proceed to San Diego, Cal., and report in person to the commanding general of the maneuver camp at that place for duty: First Lieutenants Alleyne von Schrader, William T. Cade, Jr., Herbert H. Sharpe, James F. Johnson, Bert R. Huntington, Harry G. Ford, Paul W. Gibson, Francis X. Strong and Robert C. McDonald.

The following named officers of the Medical Reserve Corps will proceed to San Antonio, Texas, and report to the commanding general, the maneuver division, for duty: First Lieutenants George E. Pariseau, Lauren S. Eckels, Lloyd A. Kefauver, John S. Coulter, Thomas J. Flynn, Frederick H. Foucar, Joseph L. Siner, John R. McKnight, Eugene G. Northington, Samuel S. Creighton, Robert H. Cantt, Edward C. Register, William Denton, George C. Divins, Howard Clarke, Clemens W. McMillan, Sanford W. French, Joseph O. Walkup, Horace M. Roberson, Leonard S. Hughes, Charles E. McBrayer, George B. Lake, Fred R. Burnside, Albert P. Clark, Daniel F. Maguire, Raymond W. Mills, Henry C. Maddux, Jay D. Whitham, Leo C. Mudd, Josiah H. Holland, John M. Willis, Josie J. Reddy, James L. Robinson, Henry C. Michie, Jr., Frank N. Chilton, Henry P. Carter, Harley J. Hallett.

Schreimer, E. R., major, March 16, reports arrival at Douglas, Ariz., with headquarters 3d Squadron and Troops I and K, 1st Cavalry.

Wolven, Homer F., D.S., March 12, returned to Vancouver Barracks, Wash., from temporary duty at Boise Barracks, Idaho.

Lynch, Charles, March 20, detailed to take charge first aid department of American National Red Cross.

Brown, Ira C., M.R.C., March 18, ordered from Fort Lawton, Wash., to Fort Douglas, Utah, for temporary duty.

Craft, Edgar D., M.R.C., March 21, relieved from duty at the Army Medical School in this city and ordered to Walter Reed General Hospital, Takoma Park, D. C., for duty.

Hemans, H. W., M.R.C., March 14, ordered to proceed from Fort Wayne to Fort Brady, Mich., for temporary duty.

Griffis, Frank C., M.R.C., March 20, ordered to proceed from Fort D. A. Russell, Wyo., to Fort Robinson, Neb., for temporary duty.

Medical Corps, U. S. Navy

Changes during the week ended March 25, 1911.

Farenholt, A., surgeon, detached from the naval hospital, Puget Sound, Wash., and ordered to the marine recruiting station, San Francisco.

Smith, W. B., P. A. surgeon, detached from the marine recruiting station, San Francisco, and ordered to the Naval Medical School, Washington, D. C., for instruction.

McCormick, A. M. D., medical inspector, commissioned medical inspector from Feb. 8, 1911.

Fiske, C. N., surgeon, detached from the Naval Medical School, Washington, D. C., and ordered to the *Georgia*.

Webb, U. R., surgeon, commissioned surgeon from Jan. 7, 1911.

Oman, C. M., surgeon, commissioned surgeon from Feb. 8, 1911.

Bachman, R. A., surgeon, commissioned surgeon from Feb. 27, 1911.

Sutton, D. G., P. A. surgeon, commissioned passed assistant surgeon from Nov. 29, 1910.

Sheehan, R. F., asst.-surgeon, detached from the Naval Medical School, Washington, D. C., and ordered to the *Minnesota*.

Eaton, W. E., asst.-surgeon, detached from the Naval Medical School, Washington, D. C., and ordered to the *North Dakota*.

Ledbetter, R. E., surgeon, detached from the naval station, Cavite, P. I., and ordered home to await orders.

Peck, A. E., surgeon, detached from the naval hospital, Canacao, P. I., and ordered to the naval station, Cavite, P. I.

U. S. Public Health and Marine-Hospital Service

Changes for the seven days ended March 22, 1911.

Cofer, L. E., asst. surgeon-general, detailed to deliver a lecture at Cornell University on "National Quarantine Measures," March 21, 1911.

Woodward, R. M., surgeon, directed to proceed to Cleveland, Ohio; Buffalo, N. Y., and Pittsburg, Pa., on special temporary duty, March 7, 1911.

Wertenbaker, C. P., surgeon, directed to proceed to Cape Charles quarantine on special temporary duty, March 17, 1911.

King, W. W., P. A. surgeon, granted three weeks' leave of absence from April 7, 1911.

Chapin, C. W., asst. surgeon, granted twenty-one days' leave of absence from March 1, 1911, on account of sickness.

Hasseltine, H. W., asst. surgeon, directed to proceed to San Francisco and report to the medical officer in command for duty and assignment to quarters.

Leake, J. P., asst. surgeon, directed to proceed to Arundel Cove, South Baltimore, Md., and report to the commanding officer of the Revenue Cutter *Algonquin* for duty.

Stevenson, J. W., A. A. surgeon, .granted nine days' leave of absence from March 23, 1911.

Cumming, Hugh S., P. A. surgeon, commissioned a surgeon (recess), to rank as such from March 15, 1911.

Cofer, L. E., P. A. surgeon, commissioned a surgeon (recess), to rank as such from March 15, 1911.

Boards of medical officers were convened to meet on April 3, 1911, for the physical examination of candidates for appointment as cadet engineer in the Revenue-Cutter Service, as follows:

Baltimore.—Surgeon W. P. McIntosh, chairman; Passed Assistant Surgeon Dunlop Moore, recorder.

Detroit.—Surgeon R. M. Woodward, chairman; Passed Assistant Surgeon M. J. White, recorder.

Boston.—Surgeon L. L. Williams, chairman; Passed Assistant Surgeon G. L. Collins, recorder.

New York.—Surgeon H. W. Austin, chairman; Passed Assistant Surgeon W. A. Korn, recorder.

Philadelphia.—Surgeon W. C. Stimpson, chairman; Surgeon J. H. Oakley, recorder.

Seattle.—Passed Assistant Surgeon B. J. Lloyd, chairman; Acting Assistant Surgeon F. R. Underwood, recorder.

Milwaukee.—Surgeon J. O. Cobb, chairman; ...., recorder.

Medical Economics

THIS DEPARTMENT EMBODIES THE SUBJECTS OF POST-GRADUATE WORK, CONTRACT PRACTICE, LEGISLATION, MEDICAL DEFENSE, AND OTHER MEDICOLEGAL AND ECONOMIC QUESTIONS OF INTEREST TO PHYSICIANS

Newspaper Editorials on Medical Subjects

The growing interest of laymen in public health and medical questions is shown by the increasing amount of newspaper space devoted to the discussion of such subjects. We quote from a few recent editorial utterances:

Under the title of "Sectarian Legislation," the Milwaukee *Free Press* discusses, in a strong editorial, the relation of the state to the practice of medicine. Commenting on the protest made by "Christian Scientists" against the bill introduced in the Wisconsin legislature providing for the medical examination of school schildren, the *Free Press* says:

> "The protest . . . foreshadows a difference of opinion certain to become acute whenever sects become numerous enough to have an influential voice in the framing of our laws. Those who would be the last to interfere with another's religious belief will find themselves constrained to protest against regulating society in general in accordance with the Christian Scientists' construction of the laws of hygiene. For suggestions of disease are conveyed not alone by medical examinations, but by every placard marking a house where some contagious disease is quarantined, by every antispitting notice, every sanitary drinking fountain, in short by every one of the precautions through which modern science seeks to safeguard health and check the spread of disease.
>
> "Experience shows that every parasite that infests the human body (and most skin diseases are parasitic) can be conveyed from one to another; that every juvenile disease, mumps, measles, chicken-pox, scarlatina, is highly contagious; that the most deadly infections that poison the human system may be contracted by contact of one with another: and that nothing could be better calculated to communicate any of them than children's games, with the playing and romping natural to all normal children. One of the reasons why a health examination is proposed for all schools is that the healthy may not be infected by the diseased, and that obscure diseases or ailments which have escaped the child's guardians, else he would not be in school, may at once be looked to and relieved.
>
> "The other reason why school children are to be subject to examination has to do with eugenics, the new science that concerns itself with the welfare of society. Observation proves that schooling is thrown away on a sickly, a hungry, or a suffering child. Only normal pupils, well-nourished and in good health, are in condition to assimilate learning; on the others teaching is worse than thrown away. Neglected teeth, abnormal growths in nose and throat, imperfect vision and hearing have been found to have much to do with the backwardness of defective children, although most of these are easily remedied in the young, and when cured the mental deficiency frequently disappears.
>
> "That is why the state is undertaking to make education effectual by attending to the physical condition of the children, and providing in case of poverty free medical, surgical or dental treatment with intent to make them first of all healthy little animals, to the end that bodily discomfort shall not incapacitate them for mental training. This is one of the most enlightened measures ever applied to the public school system, and it would be a thousand pities to let the theories of any sect interfere with it.
>
> "At present Christian Scientists are living in safety because they are a fraction of a law-abiding community. But, supposing them in the majority, the enforcement of their views would mean that there would no longer be such a science of sanitation; we should speedily revert to the era of epidemics; small-pox, cholera, typhoid, which are now avoided in crowded cities only by stringent regulation; tuberculosis, with nothing doing to abate its ravages, would soon regain lost ground, and puerperal infection would again number its thousands of victims. Modern therapy is becoming more and more a question of the prevention and combating of infection; Christian Science denies the existence of infection; on this vital issue the two are flatly opposed. Now is as good a time as any to determine whether medical experts and men eminent in research are to be our guides in matters of health."

The Louisville (Ky.) *Courier Journal*, after commending the Kentucky State Board of Health for enforcing the laws for the protection of public health says:

> "Those laws are none too strict as they are. Indeed, under them many a man is 'practicing medicine' who ought to be practicing blacksmithing and it is only flagrant cases of quackery that can be reached by the law. . . It is not an easy work at any time but when in addition to the opposition of the mountebanks themselves, it must meet the opposition of the ignorant and credulous who are the willing victims of the mountebanks, its task is one of increasing difficulty. It is a prevailing weakness of poor human nature which makes men and women—even intelligent men and women—fall so easily the prey of charlatans in and out of the medical profession. In order to help such people the law must do it in spite of themselves, and even in the profession whose protection, as well as that of its patients, is the object of the board, there are all too many who obstruct it with petty jealousies and unworthy suspicions."

Commenting on the work of the state medical society for the advancement of public health, the Columbia (S. C.) *State* says:

> "Until comparatively recent years the medical practitioners were content to give one patient at a time such relief as lay within their power and retire, but the broader and better point of view of the medical profession now is that the state, which is to say, all the people, is their care. Quietly, without advertising or ostentation, the profession has set itself to diligent endeavors to remove the cause of disease by educating the public to the truth that the conditions in which disease germinates and flourishes ought

not to exist. . . In the building of the Panama Canal, members of the medical profession have been the field leaders. They made progress possible. A great part of the state of South Carolina must be redeemed before it can be properly and profitably used by men and women, and one can think of nothing that would more quickly redound to the prosperity and happiness of the people than the acceptance of the leadership of the doctors in their efforts to bring about this redemption, a leadership which the doctors do not seek.

"The medical profession has never been selfish. It has always been self-sacrificing but its attitude has changed in that it has assumed a responsibility to the public which formerly was confined for the most part to the individual, and the invaluable opportunity of the public is to cooperate through its intelligent laymen, with a medical campaign that would assail the fortified breeding grounds of disease as well as to remove a disease or relieve pain from the particular victim that it has seized.

"This new and splendid demonstration by the medical practitioners as yet is scarcely understood by the laity but it is going on in South Carolina and if the people have regard for their interest, commercial and industrial, as well as physical, they will help the doctors and give them heed in their far-reaching activities to prevent and drive out the illness that flesh is heir to."

The Boston *Advertiser*, commenting editorially on bubonic plague and its ravages in Asia, says:

> " . . . The Massachusetts legislature has a duty to perform in making sure that the power of the State Board of Health shall be adequate and conditions favorable, for full protection of the public health. Possibly the legislature is so busy playing politics, that it cannot afford to waste much time on so trivial a subject. . . The powers of the State Board of Health are badly limited even now, as the result of agitation by commercial interests which . . . more anxious to make big profits than to keep their customers safe from contagion have pushed through former legislatures one bill after another with the idea of preventing the board's interference with the sale of products dangerous to the public health. . . It is about time for the public to take some interest in this matter. . . The public has a right to know and should know the names of the men who are trying to abolish the powers of the one board which stands between the people and the dangers of wide-spread contagion."

Discussing national health legislation, the Erie (Pa.) *Dispatch* says:

> "This country certainly needs a department of health as a regular part of its national administration. This department ought to have as much power and influence as any of the departments of the cabinet. . . One of the first tasks such a department would undertake would be the prevention of the pollution of the waters of the great lakes. The great lakes are nothing but a great open sewer for all of the large cities bordering on them. . . The cities on this lower end of the lake would feel a great deal more satisfied if the matter were officially investigated and the actual truth of the situation determined by an official study of prevailing conditions by a department of the federal government. It is entirely too vital a question to leave to the surmises and hypotheses of local boards."

The Atlanta (Ga.) *Constitution* in a strong editorial on public health says:

> "We are not at present adequately conserving the lives and health of the men, women and children whose sustained vigor is the final safeguard of American institutions. As was shown in the congressional debate last year . . . hundreds of thousands of people die prematurely and needlessly in America every year; millions are half-incapacitated the year round by semi-invalidism . . . Spending enormous sums on the pork-barrel, squandering millions on unjustified additions to the pension system, sinking money in battleships doomed to the junk heap . . . we neglect those factors on which perpetuity of government and prosperity in America depend—the men, women and children. Perhaps, in the course of time, some governmental department will find time to pay as much attention to eradicating disease among human beings as among cattle and hogs."

Discussing the relation of health legislation to industrial and labor problems the Omaha *Bee* says:

> "The American Association of Labor Legislation . . . estimates that more than 13,000,000 cases of sickness occurring annually among industrial workers, represent a national loss of three-quarters of a billion dollars. . . It should not be necessary to reduce the loss to a money basis to obtain an attentive hearing. It should be enough simply to say that human life, without any regard to a money consideration, is being wasted by lax methods of sanitation. . . . One of the sanest and best enterprises ever undertaken in this country is the conservation of human resources. . . The people are willing to waive their claim to a protest against the seeming necessity of first resolving the question into terms of dollars and cents. . . This financial aspect may serve to arouse a lethargic public conscience to the overwhelming need of improving the conditions in which women and children work as a prime factor in their health."

Newspapers frequently criticize physicians as a class and it may have seemed to some that recently the profession was getting rather more than its share of such criticism. There has never been any question, however, as to the appreciation of the physician as an individual, as shown by the recent editorial in the Washington *Herald*:

> "Of all the servants of mankind, the physician is apt to be the most abused. We criticize him and pigeonhole his bills, but at the first twinge we are jangling his bell in alarm. . . The physician is the man who must be ready always. Neither minute-hand nor hour-hand describes a time when he is not on duty. If he gets a whole night's rest, it is because the community happens to be free from aches and pains. He is the slave of telephone, night-bell, door-bell and office-bell.'
>
> "After a hard day's work, another man goes to bed with the sense of having earned his rest; but the probabilities are that the physician will be asked to respond to some one's beck and call. He is altogether a special kind of person. His illusions are few. His inside information is enormous. If now and then he wears a superior smile, forgive him. He has probably just heard some remark which he knows to be hypocritical. Again, his jokes are likely to be a bit technical, and his view of life materialistic. But if he has a brand of idealism, you can put your trust in it, for he has learned it in a hard school. He has faced the worst, and can still believe the best. If he has religion, it will be worth while, for he has wrested it out of the actual battles of good and evil in a life seen at close range.
>
> "The lawyer we take into our confidence occasionally; the clergyman we admit to parlor and dining-room; but the doctor goes into bedrooms unannounced If what he sees there surprises him, he does not let it be known. In the healing of bodies he has opportunities for healing souls which could never come to a priest. He is the lay father confessor, regardless of creed. He always fits in. He is a safe man on committees; he can turn his hand to any public business, and, if left alone, discharges it creditably. He knows more psychology in five minutes than the philosopher in a week, yet he is the least emotional of men.
>
> "When the lawyer is in tears before a jury, and the parson is pathetic from his pulpit, the doctor is keeping his nerve. The peculiar thing about him is that while fighting his grim and silent battle with death, without the applause of a crowd, often without pay, and sometimes without gratitude, he seems superior to all these considerations. He is responding to a higher sort of noblesse oblige which is almost unintelligible to the average man. Somewhere, either in this world or the next, he will reap his deserved reward."

POSTGRADUATE COURSE FOR COUNTY SOCIETIES

DR. JOHN H. BLACKBURN, DIRECTOR
Bowling Green, Kentucky

[The Director will be glad to furnish further information and literature to any county society desiring to take up the course.]

Ninth Month—First Weekly Meeting

General Subject for the Month: Diseases of the Circulatory and Nervous Systems in Children

Diseases of the Circulatory System

Physiology: Changes in circulation at birth. Pulse in infancy and childhood. Weight, size and rate of growth of heart. Physical examination of heart in infancy and childhood.

Congenital Heart Disease

Pathology: Defect in ventricular septum, in auricular septum, pulmonary stenosis, patent ductus arteriosus, abnormal origin of large vessels. Multiple defects. Secondary lesions.

Symptoms: Cyanosis, murmur, enlarged right heart. "Clubbing" of fingers and toes. Blood changes.

Prognosis.

Acute Endocarditis

Primary or secondary. Relation to rheumatism and chorea. Symptoms and diagnosis. Treatment.

Chronic Valvular Disease

Pathology: Changes occurring in valve segments, secondary changes, hypertrophy and dilatation.

Clinical Varieties

Mitral Insufficiency: Frequency, causes. Symptoms. Diagnosis.

Mitral Stenosis: Frequency, associated lesions. Diagnosis.

Aortic Stenosis: Frequency, associated lesions.

Tricuspid Insufficiency: Secondary to other valvular lesions or to pulmonary lesions. Diagnosis.

Medical Education and State Boards of Registration

COMING EXAMINATIONS

Arizona: Phoenix, April 3-4. Sec., Dr. Ancil Martin.

California: San Francisco, April 4. Sec., Dr. Charles L. Tisdale, 929 Butler Bldg.

Colorado: Denver, April 4. Sec., Dr. S. D. Van Meter, 1723 Tremont Place.

District of Columbia: Washington, April 11. Sec., Dr. George C. Ober, 125 B St., S.-E.

Georgia Eclectic: State Capitol, Atlanta, about April 20. Sec., Dr. C. W. Miller, 192 W. North Ave.

Idaho: Boise, April 4-5. Sec., Dr. O. J. Allen, Bellevue.

Minnesota: State University, Minneapolis, April 4. Sec., Dr. W. S. Fullerton, 215 American National Bank Bldg., St. Paul.

Montana: The Capitol, Helena, April 4. Sec., Dr. William C. Riddell.

New Mexico: Santa Fe, April 9-10. Sec., Dr. J. A. Massie.

Oklahoma: Oklahoma City, April 11. Sec., Dr. Frank P. Davis, Enid.

Rhode Island: State House, Providence, April 6-7. Sec., Dr. Gardner T. Swarts, State House.

Utah: Salt Lake City, April 4-5. Sec., Dr. G. F. Harding, 310 Templeton Bldg.

West Virginia: Huntington, April 10-12. Sec., Dr. H. A. Barbee, Point Pleasant.

Higher Entrance Standards

An official announcement received from the School of Medicine of Georgetown University, Washington, D. C., states that after Jan. 1, 1912, in addition to a four-year high-school education, two years of collegiate work will be required for admission; this additional work to include courses in physics, chemistry, biology and a modern language, either French or German.

Besides the forty medical colleges which require one or more years of collegiate work, there are now six others, or a total of forty-six, which by 1912 will have advanced requirements. Not only are medical colleges taking this action, but also the licensing boards in eight states have adopted a like standard as their minimum of preliminary education, and several other states are now endeavoring to secure legislation which will enable them to do likewise. It is safe to say that within the next few years all the better medical colleges, as well as the states which have secured a better control of medical licensure, will have adopted these higher requirements.

This advance will not only bring some relief to the overcrowded medical curriculum, but it will also secure for the medical schools more intelligent students who will be more able to comprehend and to make use of the intricate facts which make up the modern medical course. Certainly no measure in the effort to improve the quality of physicians is of greater importance than this decided advance in the entrance standards to medical schools.

Presented Forged Credentials

A medical student by the name of Lutf Joseph Rashid was recently dismissed from St. Louis University School of Medicine on account of his having presented forged credentials. These credentials consisted of a printed document which made it appear that he had passed successfully in all the subjects of the freshman year at the Northwestern University Medical School, where he attended in 1909-'10. Correspondence between the deans of the two colleges revealed the fact that instead of passing in all subjects at Northwestern, he had failed in three out of four branches at the end of the first semester, in six out of seven branches at the end of the year, and that he had been dismissed by the last-named school on account of poor scholarship. This incident shows that no medical school should accept credentials at their face value without obtaining corroboratory evidence from the college or colleges which the student claims to have attended. Numerous forgeries have been discovered by this method, adopted as a routine by some colleges, which otherwise might not have been detected.

Minnesota January Report

Dr. W. S. Fullerton, secretary of the Minnesota State Board of Medical Examiners, reports the written and practical examination held at St. Paul, January 3-6, 1911. The number of subjects examined in was 11; total number of questions asked, 110; percentage required to pass, 75. The total number of candidates examined was 9, of whom 6 passed and 3 failed. Thirteen reciprocal licenses were granted. The following colleges were represented:

College	Year Grad.	Per Cent.
PASSED		
Northwestern University Medical School	(1910)	79.5, 88.5
	(1908)	89.8
Med. and Surg.	(1895)	78.7
	(1909)	76.6
	(1910)	80
FAILED		
Hamline University	(1908)	66.9, 73.9
Marquette University, Milwaukee	(1910)	68.1

LICENSED THROUGH RECIPROCITY

College	Year Grad.	Reciprocity with
Rush Medical College	(1909)	Illinois
Chicago College of Medicine and Surgery	(1908)	Illinois
Keokuk Medical College, Coll. of Phys. and Surg.	(1906)	Iowa
State University of Iowa, College of Medicine	(1906)	Iowa
University of Maryland	(1878)	Maryland
Creighton Medical College	(1910)	Nebraska
University and Bellevue Hosp. Medical College	(1899)	Colorado
Columbus Medical College	(1887)	Ohio
	(1910)	Maryland
Richmond	(1907)	Virginia
ukee	(1910)	Wisconsin
Ontario	(1906)	Iowa
	(1895)	Michigan

Rhode Island January Report

Dr. Gardner T. Swarts, secretary of the Rhode Island State Board of Health, reports the written examination held at Providence, Jan. 5-6, 1911. The number of subjects examined in was 11; total number of questions asked, 70; percentage required to pass, 80. The total number of candidates examined was 11, of whom 9 passed and 2 failed. The following colleges were represented:

College	Year Grad.	Per Cent.
PASSED		
Yale Medical School	(1910)	91.5
Baltimore Medical College	(1910)	86.9
Johns Hopkins University	(1908)	90.1
University of Maryland	(1910)	80
Harvard University Medical School	(1909)	87.9
Tufts College Medical School	(1909) 81.8, (1910)	89.4
Starling-Ohio Medical College	(1909)	80
McGill University, Montreal, Quebec	(1908)	89.3
FAILED		
Baltimore Medical College	(1909)	71.2
University of Vermont	(1910)	

Book Notices

A HANDBOOK OF PRACTICAL TREATMENT. By Many Writers. Edited by John H. Musser, M.D., LL.D., Professor of Clinical Medicine in the University of Pennsylvania, Philadelphia, and A. O. J. Kelly, A.M., M.D., Assistant Professor of Medicine in the University of Pennsylvania, Philadelphia Volume 1. Cloth. Price, $6 net. Pp. 909, with 233 illustrations. Philadelphia: W. B. Saunders Co.,1911.

Renewed interest in therapeutics is indicated by the publication of several recent works dealing with diseases specially from the standpoint of treatment. This interest accounts for the present work, which is to consist of three volumes and to comprise both a discussion of general principles and a detailed application of methods to individual diseases. The first volume, a book of 909 pages, is before us. It presents the views of a large number of writers and exhibits the faults as well as the virtues of the composite book. Most of the articles, however, are excellent, as might be expected from the names of the authors.

The introductory article by Musser gives a brief but excellent discussion of the relation of therapeutics to biologic processes and the defensive actions of the organisms.

The article on serotherapy, by Hektoen, is an excellent one, and presents this important subject in a scientific manner, and at the same time in language easily understood by all. The chapter on "Drug Poisonings and Drug Habits," by Horatio C. Wood, Jr., is comprehensive and practical. "Exercise, Massage and Mechanotherapy," by F. Tait McKenzie, thoroughly covers the field. Special attention is given to apparatus, this part of the article being well illustrated. The method of reeducating the muscles in locomotor ataxia is extensively described. Among "Miscellaneous Therapeutic Measures," by George P. Müller, a description of the hyperemic method of Bier is given, and other technical methods are described.

In an otherwise excellent article on "The General Care and Management of the Sick," by M. Howard Fussell, we read: "Headache, especially of nervous character, may be relieved by acetanilid, administered in 5-grain doses repeated half-hourly for four doses." These doses are large; it would be dangerous to give 20 grains of this drug within two hours to a nervous patient. At least a word of warning should have been incorporated. Some other method of quieting nervous headaches might also have been mentioned. The author gives sage advice, however, in the same section as to the inadvisability of prescribing for cough without careful diagnosis, especially emphasizing the danger of overlooking tuberculosis; and at the same time he warns against hasty diagnosis of this disease on insufficient signs.

The article by Edsall on "The General Principles of Dietetics" is one of the most useful chapters in the book. The subject is thoroughly and scientifically discussed, and yet in such a practical way that its importance and value will be readily appreciated even by the medical student. It is a pity that such reliable and practicable information on this important subject is not more frequently found in text-books. Only praise can be given to the article by Maynard Ladd on "The Dietetics of Infancy."

The article on "Drug Therapy," by Sir Lauder Brunton, is disappointing. While it is an exhaustive discussion of the whole subject of drug therapy, one would imagine, on reading part of it, that one was reading a chapter from a text-book of a quarter of a century ago. The use of "hydrocarbons" as a term for fats, while intelligible to those familiar with the older literature, can only confuse and mislead readers accustomed to present-day chemical nomenclature. Again, the fascinating theory in vogue thirty years ago that acids inhibit acid secretions and vice versa, and that alkalies stimulate the secretions of acids, is reproduced and applied especially to the secretion of the gastric juice, in spite of the fact, long since proved by experiment, that alkalies exert no such influence on the secretory activity of the stomach.

The chapter is also sadly marred by a tendency to the indiscriminate admission of proprietaries. It is rather strange that the editors would allow such nostrums as "Phenalgin" and "Cactina" to be recommended in the book. While a discriminating discussion of the value of proprietaries that are really deserving of recognition should be welcome in a work like this, we can but regret the presentation, in so excellent a book, of such an indiscriminate list as is brought into this chapter by Sir Lauder Brunton. We feel that so far as thi part is concerned, it represents English rather than America views at the present time.

"Organotherapy," by Warren Coleman, presents a comprehensive but conservative view of the present state of knowledg regarding these methods. The rest cure, the work cure an psychotherapy are discussed by Charles W. Burr. Psychotherapy is very briefly considered in view of the extensiv notice that it has recently received. Hypnotism is rather discouraged as the author has seen distinct injury from it improper use. An interesting chapter is that on artificia aerotherapy by Henry Sewall. "Electrotherapy," by J. M Mosher, gives an excellent account of methods and indication An admirable feature of this chapter is the summing up o the present status of electricity in general medical practic in three short paragraphs. Radiotherapy is treated by H. K Pancoast. The author includes a consideration of radiu which, however, he thinks is not likely ever to equal the x-ra in general efficiency. Space does not permit a review of th articles on sunstroke by Tyson, diseases of the blood by Cabo and diseases of the lymphatic system and ductless glands b Dock. The excellency of these articles may be assumed fro the names of their authors. The other articles dealing wit minor subjects which space does not permit us to consider i detail are also excellent.

The first volume indicates that in spite of minor defect the complete work will be one of real value and if the standard set by the majority of the writers who have contribute to this is maintained in the succeeding volumes, the work wi take high rank; it certainly will meet the needs of all classe of physicians.

URINARY SURGERY. A Review. By Frank Kidd, F.R.C.S., Assis ant Surgeon to the London Hospital. Cloth. Price, $2.60. P 429, with Illustrations. New York: Longmans, Green & Co., 191

The opening statement of this book describes it as "a attempt to review for the use of the practitioner the progre of urinary surgery during the last decade." The attempt ha achieved notable success; the text is admirable in conceptio and execution—a terse, clear, complete presentation of etiolog diagnosis and the principles of treatment.

Among the few errors of sufficient moment for correctio are the following: the usual recommendation of suprapub aspiration instead of a single puncture for the insertion of catheter, as the means for the relief of urinary retentio the advice to use cocain for anesthesia of urethra and bla der—a drug usually abandoned as dangerous in the urinar channel; and the usual failure to teach that tuberculos of the urinary and genital tract results from a vice of nutr tion which must be corrected by constitutional treatmen (especially hygiene and tuberculin), to which treatment t knife is always subsidiary. In this book the local tuberc lous focus and its removal by the knife obscures the maj object of treatment—the correction of the constitution defect.

The book is worthy of recommendation to both the gener and the special practitioner.

THE PREVENTION OF SEXUAL DISEASES. By Victor G. Vecki, M.D ex-President San Francisco German Medical Society. With Intr duction by William J. Robinson, M.D. Cloth. Price, $1.50. P 132. New York: The Critic and Guide Co., 1910.

This little book contains a frank exposition of the author ideas of this complex and important subject. As causes the prevalence of venereal diseases, he gives ignorance, pro titution and alcohol. To overcome ignorance, the auth advises education all along the line. The question of alcoh he does not attempt to solve. The question of prostitutio he discusses in a sane and logical manner. He is a fir believer in segregation, as in this way only, he thinks, is possible to accomplish a humane supervision of the prostitut He condemns the reporting of cases of venereal disease an endorses the Detroit plan. What the book lacks in litera style, it makes up in sincerity and enthusiasm

Medicolegal

Information Obtained by Physician Appointed to Make Examination Not Privileged

The Court of Appeals of New York holds in the homicide case of People vs. Austin (93 N. E. R. 57), that information acquired by a physician through examination without intention or expectation of treatment is not privileged. In this case counsel for the defendant applied to the court, just before the trial, on an affidavit setting forth that the defendant was without means with which to procure the services of a physician to examine the defendant as to his sanity, so that his testimony might be used at the trial of the action, and asked that a physician be appointed to examine into the condition of the defendant and attend on the trial and testify, if the defendant so elected, and that the charge for such services of the physician be made against the county. The order was made, and the physician so appointed examined the defendant; but he was not called on behalf of the defendant as a witness at the trial. He was, however, called by the district attorney, after testimony as to the defendant's sanity had been offered, though three or four preliminary questions only were allowed to be answered, anything further being deemed privileged. That the witness should give any testimony was claimed to be error, but the court does not think that the defendant was prejudiced.

The testimony of a physician, the court says, was not excluded at common law. It is not privileged by the present New York statute (section 834 of Code of Civil Procedure), except when his information is "acquired in attending a patient, in a professional capacity," and where such information "was necessary to enable to act in that capacity." This court has frequently held that the burden is on the party seeking to exclude the testimony of a physician under said Section 834 to bring the case within its provisions.

It is clear from the statute itself and from the authorities that if the physician never attended the defendant in a professional capacity and never obtained information from him to enable him to prescribe in such professional capacity, he can testify the same as any other person. In such a case the seal of confidence existing by virtue of the statute between physician and patient and made necessary to obtain the fullest information in no way applies. It did not appear in this case from anything before the court that the physician, by what he said to the defendant, led him to believe that he was there to prescribe for him, or that the defendant by what was said by the physician was led to accept him as a physician and consequently to disclose to him information that perhaps would not otherwise have been given. Where a physician is sent to a jail by the district attorney to make an examination of the prisoner's mental and physical condition, the relation of patient and physician as contemplated by Section 834 does not exist, and the prisoner is not thereby compelled to furnish evidence against himself. There was nothing disclosed in the record in this case to show that the examination which the physician made of the defendant in the presence of his counsel was not competent, or that it was privileged by reason of Section 834.

Counterclaim Wrongly Allowed in Action for Services—No Implied Contract to Cure

The St. Louis Court of Appeals holds a new trial to be necessary in the case of Ruth vs. McPherson (131 S. W. R. 474), where the jury returned a verdict for the plaintiff for $225 for professional services, and for the defendant in the sum of $725 on a counterclaim for damages for malpractice, based on an alleged contract to heal and cure, or a net sum of $500. The court says that the jury by their verdict in favor of the plaintiff on his account must have found that the facts set out by the plaintiff in that account as to the rendition of the services and their value, and that they had been rendered at the instance of the defendant, were correct. To so find the jury must have concluded that the defense which the defendant interposed to that account, namely, unskilfulness in rendering them, was not sustained; that is, the jury by their verdict of $225 on the account in favor of the plaintiff necessarily found against the defendant on all of his averments as against that account. Having so found, then to turn round and find a verdict in favor of the defendant on his counterclaim, which counterclaim, to all intents and purposes, was founded on the identical defenses set up to the account, was utterly irreconcilable with the verdict in favor of the plaintiff on that account. Hence, as being inconsistent with itself on the issues, the verdict, as a whole, could not stand. Moreover, the counterclaim was specifically based on an alleged special contract whereby the plaintiff undertook as a physician and surgeon to attend and to cure and heal the defendant, but there was not an iota of testimony to prove any special contract. It is not within the implied contract of a surgeon employed to operate, or of a physician to attend on a patient, that he will heal and effect a cure. Any such contract must be an express one; it is not implied by the mere employment. To use skill, etc., is all that is implied in the mere employment of a physician or surgeon. Considering the averments of the counterclaim in this case, on which the defendant recovered damages, and in which counterclaim the averment of the contract to heal and cure was distinctly contained, the court holds it to be an averment which could be sustained only by proof of an express contract, a contract outside of the implied contract under which a surgeon is employed.

Latitude Allowed in Hypothetical Questions

The Supreme Court of Indiana says, in Taylor vs. Taylor (93 N. E. R. 9), that a party may put his hypothetical case as he claims it to be proven, or within reasonable inferences from the evidence, and the jury determines whether it is so supported by the evidence as to be of any value, or as to the weight and value they will give it. The opinion may be tested by cross-examination, by omissions and additions to the original question, or by an entirely new state of facts. If facts are assumed in a hypothetical question which are clearly so exaggerated as to impair the opinion, or are such manifest assumptions as to be misleading, confusing, and aside from evidence or fair inferences from the evidence, it should be excluded, and its admission might be prejudicial error in a given or specific case. But the weight and value of the opinion is a question for the jury, and depends for its value on there being evidence, admissions, or facts proved, on which it is based. And even if the question is faulty by the insertion of some facts not supported by the evidence, so that, uncorrected, an error might occur, it is corrected by an instruction to the jury that, if any of the material facts contained in the question are not shown by the evidence to be true, they are not to be taken as true, because embraced in the question, and, if of such character as to destroy the reliability of the opinion based on the hypothesis stated, the jury should attach no weight whatever to the opinion.

Medical Practice Act Not Invalidated by Provision as to Prayer

The Court of Appeal, First District, California, holds, in Ex parte Bohannon (111 Pac. R. 1039), that the medical practice act of that state of 1907 is not rendered unconstitutional by the proviso that nothing therein shall be held to apply or to regulate any kind of treatment by prayer. It was contended that this exemption made the whole act unconstitutional and void, and that it gives to a certain class of persons, to wit, those who treat physical ills by prayer, privileges and immunities, which "under like conditions are not granted to all citizens." But the court does not so construe the section. If prayer can be regarded as practicing medicine and as an immunity, the act, the court says, allows every person, man, woman or child, such immunity and the right to pray for the sick and afflicted, and that is the only way that disease can be treated by prayer. Whether such treatment avails anything or not is not for the court to say; but the privilege of practicing such treatment or such supplication is granted and allowed to all. The proviso or exception was evidently put into the act to prevent any interference with the right of any one to pray for the sick and afflicted.

NATIONAL CONFEDERATION OF STATE MEDICAL EXAMINING AND LICENSING BOARDS

Twenty-First Annual Meeting, held in Chicago, Feb. 28, 1911

The President, Dr. Joseph C. Guernsey, Philadelphia, in the Chair

An address of welcome was delivered by Dr. George W. Webster, Chicago, which was responded to by Dr. Lee H. Smith, Buffalo.

Dr. Guernsey delivered an address on medical licensure.

Officers Elected

The following officers were elected: president, Dr. Charles A. Tuttle, New Haven, Conn.; vice-presidents, Drs. James A. Egan, Springfield, Ill., and A. B. Brown, New Orleans; secretary-treasurer, Dr. George H. Matson, Columbus, Ohio; executive council, Dr. N. R. Coleman, Columbus, Ohio, chairman; Dr. Charles H. Cook, Natick, Mass.; Dr. Joseph C. Guernsey, Philadelphia; Dr. W. Scott Nay, Underhill, Vt.; Dr. James A. Duncan, Toledo, Ohio.

Chicago was selected as the place for holding the next annual meeting.

Flexner Report

Mr. Abraham Flexner, New York City: In my report to the confederation last year I pointed out: (1) The education prerequisites should be defined, and the board authorized to insist on it as an educational preliminary. (2) The enforcement of even the four-year high school standard will so far clean up the medical field that the state boards will at once be relieved of the duty of dealing with actually disreputable schools. (3) The examination for licensure is the lever with which the entire field may be lifted; for the power to examine is the power to destroy. A model state board law must guard the following points: the membership of the board must be drawn from the best elements of the profession, including those engaged in teaching; the board must be armed with the authority and machinery to institute practical examinations, to refuse recognition to unfit schools, and to insist on such preliminary educational standards as the state's own educational system warrants; finally it must be provided, either by appropriation or by greatly increased fees, with funds adequate to perform efficiently the functions for which it was created.

REPORT OF REFERENCE COMMITTEE

The committee to whom was referred the Flexner report, composed of Drs. W. J. Means, N. P. Colwell and Henry Beates, made the following report, which was adopted:

The recommendations made in Mr. Flexner's paper concern subjects which have been frequently presented and discussed at meetings of this confederation, as well as of the Association of American Medical Colleges and of the Council on Medical Education. We recommend, therefore, that most careful consideration be given to all the suggestions made, and that the three special recommendations, regarding preliminary education, the refusal to recognize poorly equipped schools and practical examinations, be adopted.

SYMPOSIUM ON STATE CONTROL OF MEDICAL COLLEGES

Could the State Control and Conduct Medical Colleges More Efficiently than Corporations and Private Individuals?

Dr. C. W. Dabney, President of the University of Cincinnati: Let us state the proposition in the following terms: public control of medical colleges through state, municipal or other public corporations, including corporations which, though not state or municipal in name, still by reason of their breadth and importance, really represent the entire public, should be expected to conduct medical colleges more efficiently than private corporations or private individuals. We should plan for the best organization of the medical college as a part of our system of public education. The duty of the state is being better and better understood, with the result that in the last two years many of the state universities have established colleges of law, of medicine and of dentistry, as well as of engineering, colleges for teachers, etc. The chief argument for public-supported institutions in a democracy is the necessity of making them accessible to all classes of citizens on equal terms. To exclude the poor from the opportunities of the highest education, including professional education, or to educate them only at the bounty of the wealthy, is utterly repugnant to our democratic ideals. It is eminently desirable that the wealthy should give of their surplus to endow and support public institutions. The best location for a medical college is where it will enable it in the most efficient manner to perform three great duties to the public: (1) The education and training of properly qualified youths for the profession of medicine and the service of the people in families, dispensaries and hospitals; (2) the advancement of science through experiment and research; (3) the education of the people in health and principles of preventive medicine and sanitation.

The Duty of the State in the Control of Medical Colleges

Mr. Abraham Flexner, New York City: There should be state control of medical colleges. This control should be indirect in the sense, first, that the state shall determine the date of registration of each medical student by setting a standard of preliminary education and permitting the student to begin to count his time of medical study only after the state has declared his *preliminary education* completed; second, that the state shall require a minimal period of medical study in a properly equipped medical school; third, that the state shall register for *practice only such individuals* as give evidence of having obtained a certain minimal knowledge of medicine as determined by examination and practical tests, etc.

Discussion on State Control of Medical Colleges

Hon. Charles Alling, Jr., Chicago: If the courts will sustain as a requirement for examination a diploma from an institution of the standards upheld by the Association of American Medical Colleges, they should for the same reason sustain a law providing that the degree of M.D. shall be given only by medical colleges in good standing with the State

Board of Medical Registration and Examination, an official body created by and acting for the state to secure good medical service for all the people.

Dr. Victor C. Vaughan, Ann Arbor, Mich.: The practice of medicine is under any and every condition a public service. No man can practice medicine without rendering a public service. Every physician present who attends a case of scarlet fever, diphtheria, or anything of that kind, may do the best he possibly can for his individual patient, yet he is rendering a hundredfold greater service to the state. He is preventing the spread of that disease. The practice of medicine is necessarily a public service, and it has been decided by the Supreme Court of the United States that the regulation of it lies within the hands of the state. The state has a perfect right to put any regulations that it pleases on the practice of medicine. We should impress on the people, and especially on those connected with state universities that are teaching medicine, that the most important function we have to perform is the enlargement of medical knowledge.

Dr. George H. Hoxie, Kansas City, Mo.: The majority of the people do not accept the fundamental principle that they have a right to restrict the practice of medicine, because the higher we get our standards, the more likely are they to permit the followers of the isms and pathies to practice medicine under one guise or another; thus showing conclusively, in my opinion, that they have not accepted that fundamental principle, but have simply been yielding to the pressure brought to bear by physicians. It is only when the people of the state become convinced of these fundamental principles that there is any hope of controlling medical colleges from without or of adequately supporting them.

Dr. James R. Guthrie, Dubuque, Iowa: If it be true that the future of medical education is largely in the line of preventive medicine, public hygiene and sanitation, is it not the highest duty and prerogative of the state to accept that situation and make it obligatory and place the power of the state behind this, the leading and controlling idea in modern scientific education?

Dr. George Blumer, New Haven, Conn.: I think it may be said that even when the appointment of state medical examiners is in the hands of bodies like state medical societies, we cannot entirely rule out the possibilities of political appointment, since politics enters into state medical societies as well as into the executive positions of the state. Another point of interest is the matter of representation of teachers on the state board of medical examiners. I think every teacher of experience has felt very critical at times toward the kind of questions that are put to students by a great many state boards of examiners. Members of the state board of examiners are not always selected with the idea in mind that they are to examine students trained in modern medical schools. For instance, there should be a man on the board of examiners who has been trained by the modern methods in such subjects as pathology and bacteriology, and it seems ridiculous to expect a man who has not received that kind of training to ask intelligent questions on those subjects.

The Advantages to Medical Colleges of State Control

Dr. Arthur Dean Bevan, Chicago: Proper state control would mean a great deal and be of great advantage to the medical colleges which are doing good work and developing along scientific lines. I believe that if every state board represented in the confederation will attempt to get the profession of its own state back of it and make proper state control effective, within five years American medicine could be placed in a position, with the exception of a very few states, where we could say that the American medical student is obtaining the proper medical education; that he has had a proper preliminary and medical education, and some practical hospital experience before he is allowed to practice medicine.

Some Evils in the Present System of Medical Education

Dr. F. C. Waite, Cleveland, Ohio: The evils of overproduction of medical graduates are self-evident. First, the field is overstocked, consequently the average income and adequate living are reduced. Second, from this the result must be that the more able members of following generations will shun the profession and its recruits must come from the mediocre. The general tone of the profession will thereby diminish. Third, the average lack of income from reputable and ethical practice of the profession will lead many into quackery and charlatanry, and thereby yet further reduce the dignity and respectability of the profession, which again will divert the tendencies of able young men from the profession. Medical teaching, even if privately supported, so closely affects the public that it must be considered a public utility, and therefore subject to the control of the commonwealth. The number of schools in a given state can be limited, either arbitrarily or by forcing public opinion to a level where the cost of maintenance of a school will exceed the private advantages accruing. This may be done by a close supervision of entrance requirements, by insistence on adequate laboratory equipment and clinical opportunities; by limiting the student body to the more capable. By examinations the average capability of the students can certainly be controlled. It is very important that practical means be found to eliminate men who do not measure up to the promises indicated by their preliminary training. The lack of this needed elimination of the unfit is one of the weakest points of our present system. The last two years, during which discussion has been free and meetings of representatives of various schools frequent, have shown a tremendous growth of interest on the part of each man and each school in the common cause. The further equalization of interests that would come from more centralized control would yield a further community of interests among the schools. A standardization of equipment and facilities, and the establishment of a minimum of opportunity for each student would secure a product in the graduate that would gain the confidence of both laity and profession. A control of the student's training at the time of admission, rather than an examination of his shortcomings after the evil is done, would be far more just to the student, who is too often innocently a victim of a system which seems to employ every means to mislead him and none to protect him. State control of medical education, like municipal ownership, has the potentiality of great blessings, if properly managed; but too often it is capable of many pitfalls if unwisely construed. To work out and put into operation all the details of such a plan is no light task. To gain the balance between ideals and expediency between the desirable and the possible requires rare judgment and altruistic devotion.

State Aid in Securing More Full-Time Salaried Teachers

Dr. Frank Winders, Columbus, Ohio: That full-time salaried men are indispensable to the proper teaching of the first and second years of the medical curriculum is no longer questioned. This plan is now in practice in every first-class medical school. The true purpose of a medical college is to be found only in teaching the science and art of medicine to the end that its students and graduates may be best equipped to prevent and relieve the ills and accidents of mankind. When other aims and purposes creep into the scheme of medical teaching, such as the personal interests of the teacher, the standard is lowered, the quality of instruction suffers, and the unfortunate student, not the teacher, pays the penalty. The teacher whose chief purpose consists in increasing his clientele by his teaching can certainly not develop the best that is in the student. Adequate compensation in proportion to the time required and to the excellence of the service rendered would do much to correct the evils resulting from the present practice. No modern medical college can be successful in its truest sense, unless it has at its disposal the wards of one or more large hospitals, and an adequate dispensary service. It is in such institutions that the material for successful clinical teaching must be obtained, and at least a part of the teaching staff in general medicine and surgery should be free to devote their entire time to such clinical work and to their duties as teachers. A college which does not have in its hospitals and dispensaries sufficient clinical material, properly utilized, to keep one or more teachers of general medicine and surgery busily occupied for their entire time, should not be permitted to remain in existence. One clinical case properly and exhaustively analyzed and demonstrated will have more real value than many which are presented in an incomplete and hurried manner. If medical schools were aided and controlled by the state, the same excellent conditions would obtain in all schools as are found in our state universities.

State Control of Medical Education and Enforcement of the Medical Practice Act

DR. EDWARD CRANCH, Erie, Pa.: The function of medical examining and licensing boards is judicial: deciding between the claims of the candidate backed by his college on the one hand, and the rights of the people, who need protection from the ignorant and unqualified practitioner, on the other. Licensing boards should also have the power of revoking licenses for cause shown. In the exercise of their function, in Pennsylvania, the examining boards were at first greeted with a defiant attitude by certain colleges whose faculties assured their students that it was of little or no consequence whether they passed the boards or not, the colleges would see that they had the right to practice anyhow—whatever the boards might say or do. This attitude was signally crushed by the results of one year's examinations, in which over 30 per cent. of candidates were rejected. If now, as under state control would be the case, examiners and teachers knew better what was coming, the work of both would be easier, but at the same time, if written examinations alone were to be relied on, chances for cheating would increase in equal measure. When the student knows that his record of study and standing in class will count for or against him, and when he knows that he is to be orally and practically examined, if only in some few departments, such as anatomy, materia medica and diagnosis, it will improve his whole method of study and render it more practical. The method of full control would be suitable for one or two colleges in each state, and then if others wish to organize, as now, they can, under a modified control, be rendered equally efficient, and yet preserve that initiative which will develop new and better methods for the future. In this way examining and licensing boards will find their work supported by the colleges, instead of being antagonized and criticized, as at present. This alone furnishes a good argument for at least a modified state control.

Result of State Control of Medical Colleges on Professional Efficiency

DR. ROYAL S. COPELAND, New York City: When one considers the really ideal condition as regards medical college supervision, naturally he thinks of the superior advantages of federal control, with uniform standards of admission, graduation and licensure. This, however, is impossible at present, and perhaps would be unwise. Of necessity, low standards will prevail in pioneer and undesirable sections of the country, and a federal law, in striking an average for the country at large, would raise a much higher standard than could obtain in many of the individual states. State control, therefore, is the present logical solution of the problem. In the matter of medical colleges, private control undoubtely results in abuses and a lower standard than should be tolerated at the present time. Certainly private control must mean lack of uniformity. In a given state, for instance, with private control, there will be of necessity as many standards of admission and graduation as there are colleges. With state control, while the standards may be no higher than the average of the private institutions in another state, at least there is uniformity in the administration of the colleges. There is uniformity as to the minimum requirements, with perfect liberty of diverse views as to the maximum. State control has all the benefits of federal control, if there are reciprocal relations between the states. This reciprocal relationship, so desirable to our profession, would be much easier to realize were there uniformity in the college curricula, as regards the essentials of medical education. The great argument for state supervision is the protection of the people against charlatans, quacks and poorly educated practitioners. Legislation providing for state supervision should include the conditions under which medical college charters may be issued, and the minimum requirements of preliminary and professional education. State supervision should include the right to revoke, for due cause, the license to practice medicine. The natural corollary of state supervision is reciprocity between the states. To this end there should be uniform laws and requirements. State supervision makes for more uniform and thorough education.

Report of Committee on Materia Medica

DR. MURRAY GALT MOTTER, Washington, D. C., presented the list of medicaments reported last year in alphabetic order. Personally, he sees no advantage from the standpoint of the confederation in a list classified under any system whatsoever. The important thing to know is to what medicaments with their preparations it is desirous that chief attention shall be given, and he suggested that it would be both interesting and profitable to have a complete alphabetic list, including the list submitted by the joint committee last year, the list submitted by the Chicago Medical Society and adopted, and a list from the English examiners recently received by him from Dr. Cushny. A printed (complete) list is needed showing the drugs which are named in all three lists, and then the profession will have a competent list of drugs having wide use both in this country and in Great Britain. The future work of the committee on materia medica should be directed along the lines of securing endorsements of this general proposition. The list itself is not of such vital importance as the general proposition to adopt a restricted list. Then, if the teachers will devote their time and attention to this list, and if every medical examining board should say we will grant say 75 or perhaps 80 per cent. in the subject of materia medica pharmacology for examinations on this restricted list, it would leave the field open. It would not oblige any board to restrict itself absolutely to the list or prevent any teacher from teaching anything he might wish to teach. So it would leave the field open and mark a decided step in the progress for a more sane therapy.

ASSOCIATION OF AMERICAN MEDICAL COLLEGES

Annual Meeting, held Feb. 27-28, 1911
(Continued from page 843)

The Medical College Library

DR. C. M. JACKSON, University of Missouri: The medical college library is an important but neglected factor in medical education. It supplements the laboratory and clinic by making available the accumulated knowledge and wisdom of the whole world, both past and present. The library should be carefully selected, quality being more important than quantity. Of the various forms of medical literature, the standard periodicals are by far the most important. Students should be instructed in the use of medical literature. A good library is indispensable in encouraging that research spirit which should be the ideal in medical education. Through his experience in daily practice the practitioner learns something, but through the medical literature he learns to interpret this experience and to profit by the experience of others.

The medical college library should include 4,000 or 5,000 well-selected volumes; especially it should include subscriptions to at least 100 of the leading medical periodicals. It is doubtful whether there are now more than twenty medical schools in the United States which meet this demand. More could easily do so, and doubtless will when the value of the college library in medical education is better understood. Periodicals are far more important than text-books, which are at best only compilations made from periodicals. Good periodicals contain original observations. There should be periodicals more or less general in scope and those devoted to the individual laboratory and clinical subjects. Some of the principal French and German journals should be included, as the better class of medical schools now require a reading knowledge of these languages. Under periodicals should also be included the transactions of the more important medical societies and hospital reports, which contain much of permanent value. Next to periodicals in importance come the various guides to medical literature—the Index-Catalogue of the Surgeon General's Library, the *Index Medicus*, German *Jahresberichte*, and others might be mentioned. Next in importance stand the dictionaries, encyclopedias, systems of medicine and surgery, handbooks and monographs, and, last of all, the text-books.

A trained librarian should be in charge. A faculty library committee should select the books and periodicals to be placed in the library. The funds necessary should be provided for in the annual budget. To maintain a good working library will require an annual appropriation of at least $1,000. Some good can be done with less. The students can be called on for assistance, likewise the faculty, and some donations from outside sources can be secured. The library should be accessible, catalogued and kept in order. Originality and independence of thought should be encouraged by frequent references to various sources in the best medical literature. It is important to make students familiar with the best sources of medical literature, how to find and use them. Instruction on these points should be given in the first year of the course by the librarian or some one competent to do so.

Every student before graduation should be required to write an original thesis on some subject of his choice, which, of course, will include a review of the literature. It would stimulate teachers and students to better efforts along this line. Only two schools, Yale and Bowdoin, now have such a requirement.

The following resolution was introduced by the Committee on Pedagogics and was adopted:

Resolutions

Resolved, That the association request each school to ascertain and file in the dean's office the estimate of each instructor as to the time required, both in the class-room and at home, in each course offered in the catalogue.

Resolved, That the judicial council be instructed to report at the annual meeting in 1912 as to the proper standard to be established for medical colleges in various sections of the country, and that the judicial council be instructed to confer with the Council on Medical Education of the American Medical Association and with the Carnegie Foundation for the Advancement of Teaching in the hope that these three bodies may agree on a minimum standard that may be applied practically at the present time.

Resolved, That the judicial council be requested to report at the same time as to the best methods of carrying out the inspection of colleges in membership in the association as provided for in the by-laws, sections 6 and 7, and of schools applying for membership in the association. (These two resolutions were introduced by the Committee on Medical Education and adopted.)

Report of Committee on Equipment

The committee pointed out the great need for securing proper clinical facilities, and urged the colleges to formulate plans tending toward the acquisition of a teaching hospital, a hospital in which all the material is available for teaching purposes. The committee urged that this be made an equipment requirement, as much so as microscopes and other apparatus used for teaching.

Report of Committee on Pedagogics

The committee offered suggestions on four topics:

1. The Unit of Credit:—Students should be given time for independent analytical thought. The average student cannot work profitably, either in class or by himself, more than twelve hours a day for five days in the week, or for ten hours a day for six days in the week. Sixty hours a week should be the optimum number of hours under average conditions. This for thirty-two weeks of actual teaching means 1,920 hours, or for thirty-six weeks, 2,160 hours. The committee recommended the recognition of a ratio of two hours of preparation or reading to each hour of recitation or lecture, and one hour of preparation or reading for each two hours of laboratory or clinic teaching—a three-hour unit. Catalogues should state how these hours are subdivided in each course.

2. Discussion of Pedagogic Principles:—The committee suggested that the regular faculty meetings be given over to the discussion of these principles, best under the guidance of some professional teacher brought in for the occasion. The oftener such meetings are held, the better.

3. Syllabus:—A syllabus of the courses of study in the curriculum is a necessity because of the increasing specialization and subdivision. It will avoid misunderstanding and amendment.

4. Training of Teachers:—Can clinical teachers be efficient without private practice? The committee made no recommendations or suggestions, but presented the opinions of three men. One, a clinician with only hospital training, did not believe that any particular form of training could be mapped out as a prerequisite for clinical teaching. To be successful he must have the *Geist* and be trained thoroughly. The best man is he who devotes his time to work in the fundamental branches, to clinical work in the hospital and a moderate amount of consultation practice. Private practice is time-consuming, leaving little time for development. There should be two classes of clinical teachers: those who devote a large part of their time to medical school work and those who devote a small part. The second, a man who has enjoyed private practice, said that it is impossible that a man should carry on a medical practice and at the same time conduct a medical department in a hospital and teach students. A moderate amount of time may profitably be spent in consultation work. The third, also a man who has had private practice, regards some training in private practice as being as essential as a training in chemistry, bacteriology or pharmacology. But such training must be limited because otherwise other equally essential training will be neglected. He, too, favored some consultation practice because of its educational value and the necessary intercourse with practicing physicians which it furnishes.

CLEVELAND ACADEMY OF MEDICINE

Meeting held Feb. 17, 1911

DR. W. B. LAFFLER in the Chair

Some Common Fractures and Results of Treatment

DR. FREDERICK J. COTTON, Boston: The Roentgen ray has wrought many changes in the point of view of treatment of fractures, and has enabled us to work with more precision. What we want is, first, the avoidance of obvious deformity, and second (much more important), the attainment of good functional usefulness. Most troublesome cases are the result of (1) not checking results by the Roentgen ray; (2) associated nerve lesions being overlooked at first, and when found, attributed by the sufferer to the treatment; (3) forgetting that functional usefulness is the main aim and caring only for position in all cases of Colles' fracture along with radial fracture there is a forward dislocation of the ulna, and in effect on functional result this is of more importance than radial fracture. After reduction splints should be applied: (1) to protect radial fragments from trauma or muscle contraction; (2) to hold the ulna back where it belongs (it can't be held too far back); (3) to be comfortable. Splints should not confine thumbs and fingers, and active motion should be started not later than the third day. The posterior splint should be removed in one week and all in from ten days to two weeks. In elbow fractures in adults, after reduction by traction and direct manipulation, the arm should be put in the position in which the fragments are most firmly held, and the best splint is the one which best accomplishes this. The Roentgen ray should be employed to see that reduction is good. Within a week, with fractures of one condyle, and within two weeks, with fractures of both condyles or in T fractures active motion is allowed once a day. The surgeon should hold the fragments firmly and support the forearm. In children, elbow fractures are usually more or less complicated epiphyseal separations. After the fracture is reduced what of treatment? (1) Passive massage and motion in children only stirs up joint reaction, pain and stiffness. (2) Active motion, without danger of slipping of fragments, is hard to control in children, and is not to be employed for four weeks. (3) Children with elbow lesions do not show any permanent stiffening (except from malposition of bones), so that we need not worry about reestablishing motion. (4) Separation of the external condyle shows many instances of non-union; separation of internal condyle always results in fibrous union.

Shoulder fractures are commonly of the anatomic or surgical neck. The former are usually impacted and occur generally in the aged. They had best be left alone and mobilized early. Fractures of the surgical neck occur generally in youths or strong adults and if there is great difficulty in reducing, I have no hesitancy in cutting down and levering fragments into place, when a stitch of chromic gut will hold them. Though this is a serious operation, I believe that separation of the humeral epiphysis or fracture of the surgical neck in vigorous persons will come to be recognized as a condition calling for early operation in a large percentage of cases. In leg fractures, the question that comes up is whether after reduction the position is not good enough to let go, not whether it is perfect, for perfect reduction is impossible. The general line of the shaft should be good, and a position must be avoided in which the outer side of the periosteum of one fragment is brought into contact with a similar surface of the other fragment as it presages non-union from poor formation of callus.

The commonest of all ankle fractures is a fracture of the fibula alone, and it may occur from inversion or eversion. The former is more common. A not uncommon fracture, which is not described in text-books, is a splitting off of a large portion of the back edge of the tibia in a fragment that carries the internal malleolus as well. The fibula is also broken. The foot, astragalus, tibial fragment and lower fragment of the fibula move backward together.

As to the disability of the ankle joint following fractures, we have three important factors, mostly independent of precise lesion: (1) distortion of joint surfaces, causing unnecessary joint friction and limitation of motion; (2) deviation of weight-bearing axis; (3) loss of function (due to long immobilization). In reducing such lesions we should aim to alleviate these faults as much as possible and use early, active motions, preventing stiffening.

DISCUSSION

Dr. Frank E. Bunts: In the last five or six years our ideas of the treatment of fractures have materially changed—due to the use of the Roentgen ray. Does Dr. Cotton think that ischemic paralysis is due to tight splints or to faulty position of the splints, and how long does it take to produce it? I find that Mr. Lane, of London, thinks the periosteum of no value in the formation of callus. What does Dr. Cotton think of the use of Bier's passive hyperemia in delayed union in fractures? In the last few years fractures of the carpal bones have attracted the attention of many; especially since the Roentgen ray has shown many of the so-called sprains to be fractures. Does Dr. Cotton believe in operating and removing the fragments when they are especially difficult to reduce?

Dr. J. F. Hobson: I agree with Dr. Cotton that a Colles' fracture once reduced does not usually become displaced again. In a Pott's fracture we have always been taught that the three lines of fracture were (1) lower end of fibula; (2) internal malleolus, and (3) a small chip that was generally broken off the outer edge of the tibia. I see that Dr. Cotton did not mention the latter, and I would like to ask him about its relative frequency. In a fracture functional result is what is first desired, second, as near a return to the normal as is possible.

Dr. G. W. Crile: Surgery is once more beginning to turn from the abdomen to the bones and joints. The latter have been neglected and it is high time that the specialist and general practitioner make a careful study of the bones and joints.

Dr. George B. Follansbee: I have found in all fracture cases that early movement of the joints is of great value and tends to prevent adhesions and stiffness. I would like to ask the speaker whether it is always possible to reduce a dislocated ulna in a Colles' fracture. At times I have great trouble in doing so and also in keeping it in place. Does it make much difference whether the styloid process is much separated in a Colles' fracture?

Dr. W. O. Osborne: I have at present two old cases of Colles' fracture. In both there has been left a preternatural mobility of the ulna; the joint is also a little painful and a trifle weak. Is there any way to remedy this?

Dr. F. J. Cotton: Ischemic paralysis is often difficult to separate from a nerve paralysis. I have seen very few cases of it. In one case in which there was a cord-like matting together of the muscles, I found it necessary to rupture the bellies of the muscles, and the patient has now a pretty good use of his arm. Another patient was improved by dissecting out the muscles and freeing the nerves, and, I think many of these cases of Volkmann's ischemic paralysis are due to nothing but pressure on the nerves. In such cases I would recommend dissecting out the nerves and clearing away the muscles. In contrast to Mr. Lane, I still believe the periosteum to be of great value in the formation of callus. However, I do not think that stripping away the periosteum causes death of the bone as was formerly taught, and in case of necessity I have no hesitancy in stripping it away. I feel that very little is known as to the cause of delayed union from internal diseases—outside of malignancy and diabetes. Locally, delayed union may be due to a faulty parallel position of the periosteum from the fragments lying side by side. In regard to Bier's passive hyperemia treatment, it may be of interest to say that its author now thinks so little of it that he has given it up. In fracture of the carpal bones, it is usually the scaphoid that is affected and often displaced. When the bone is merely cracked, there is frequently a union without any limitation of motion or thickening of the bone; and I generally do not operate in these cases. However, if the bone is broken, displaced and not reducible, we must cut down and remove the displaced fragments. In answer to Dr. Hobson, I might say that I do not feel that a broken chip from the outer edge of the tibia is characteristic of a Pott's fracture. I agree that to hold the ulna in place is one of the difficulties in treating a Colles' fracture. Recurrent luxation of the ulna, after an old Colles' fracture is one of the sequelæ at times, and in a bad case I would cut down and shorten the radio-ulnar ligaments. I do not believe in operating and undergoing any extra risk. In a large percentage of shoulder cases it is necessary, and one should operate before too much callus has formed.

PHILADELPHIA COUNTY MEDICAL SOCIETY

Meeting held Feb. 8, 1911

The President, Dr. C. B. Longenecker, in the Chair

Pellagra

Dr. Samuel Stern: The sense of security of the profession at present against the invasion of the pestilence is unwarranted. Pellagra will be found whenever one finds the factors necessary to cause the disease. The conditions are more widespread than heretofore credited, and it is the duty of the profession and the local and state health authorities to engage in a study of the disease in order that measures may be instituted to aid in its prevention and in the possible discovery of the cause and that a successful method of treatment may be found.

A Case of Pellagra Which Had Its Origin in Pennsylvania

Dr. M. B. Hartzell: G. R., aged 9, has spent all her life in Pennsylvania, most of it in Philadelphia. In August, 1909, she began to lose flesh, became melancholic, and some time later developed diarrhea. In the spring of 1910, a peculiar red-brown dermatitis of the hands and face developed. During her stay in the hospital there was considerable improvement, but soon after her discharge she grew worse and she died in October, 1910. All her symptoms were characteristic of pellagra. The eating of spoiled corn could be excluded as a causative factor with reasonable certainty. During the summer of last year I had the opportunity to study the disease as it occurs in northern Italy, and from the observation of a small series of cases I am convinced that in mild cases and poorly developed ones, the diagnosis may be surrounded with considerable difficulty; and that it is a mistake to lay too much stress on dermatitis and pigmentation unless accompanied by other symptoms, especially gastrointestinal.

DISCUSSION

Dr. Frank C. Knowles: I feel that the diagnosis of pellagra is almost impossible unless there are present the three Ds: diarrhea, dementia and dermatitis.

Dr. Leonard D. Frescoln: I have had two cases in Philadelphia which were suspicious of pellagra; but I have never seen any cases which were diagnosed to my own satisfaction by the authority of those who had seen the real disease in Italy. There has been shown no positive proof by blood-tests that from my study and reading I believe we should have. To the three Ds mentioned by Dr. Knowles, there should be added a fourth, that of "death." My impression is that practically all these patients die. They improve for a time, but finally die without any other manifest cause of death.

Dr. George E. Price: One is impressed with the great variety of mental symptoms that have been reported in association with pellagra. This is in a large measure due to the fact that many cases are found in the asylums for the insane. If there be any insanity of pellagra, it seems to me that it must from necessity follow the line of insanity of any infectious process. If we have a destructive agent sufficient to cause the changes that have been noted in the spinal cord in pellagra, we surely have a destructive agent sufficient to bring about pathologic changes in the brain and membranes. The cord changes have been those of a combined or diffuse sclerosis, comparable to the changes found in anemia and toxic states.

Dr. A. E. Roussel: My experience has been confined to four cases seen in South Carolina two years ago. The erythematous eruption in three of the four was marked. The necropsy findings were interesting in showing the earlier involvement of the membranes than of the cord proper. I feel that a thorough bacteriologic examination should be made before we assume definitely that every case of eruption of this or that type is pellagra. Even those experienced practitioners from neighborhoods where the disease abounds realize the difficulty of diagnosis in the early stages. Every safeguard should be adopted against the error of hasty diagnosis.

Dr. S. Stern: Regarding the relation of insanity to pellagra, abroad the figures vary from 10 to 30 per cent. Over 80 per cent. of the patients are not insane. Probably a very small percentage show any nervous manifestations. While it is true that dermatitis, dementia and diarrhea are important factors, and that their presence aids in diagnosis, I do not attach the same degree of importance to them as do some. The addition of "death" is out of order, since we desire to make the diagnosis in the early stage of the disease and not at the end.

The Destruction of Surface and Cavity Neoplasms by Desiccation

Dr. W. L. Clark: My work up to the present time would appear to justify the conclusions: 1. A current from a static machine of large output with properly attuned accessories, is capable of destroying tissue by desiccation. 2. Malignant growths *may be destroyed* without opening blood or lymph channels, thereby preventing further metastasis, or the inoculation of healthy tissue in adjacent parts. In cancer of the breast, in which there is involvement of the axillary or cervical glands, operation is indicated on account of inaccessibility of the involved structure; but, on the first appearance of recurrence, there would be a great possibility of arresting activity. In cancer of the cervix I believe it to be more desirable than the curette and cautery. It is a perfect sterilizing, destructive, styptic deodorant and is penetrating. It can be employed with a minimal degree of danger and discomfort and may offer a chance of cure if taken in time. 3. It simplifies the treatment of hemorrhoids and other neoplasms of the mucous membranes. Employing the endoscope as an aid, cavity lesions may be treated successfully. Its applicability in the bladder has been shown, and it is perfectly possible to apply it deeply into the rectum, the interior of the uterus, the throat, the esophagus and even the stomach. 4. In warts, moles, pigmentations and in certain other cutaneous lesions, the destruction is a simple matter and the cosmetic effect good. Old pus sacs may be entered, destroyed and sterilized, as in pustular acne, etc. Sluggish ulcers may be stimulated to repair. 5. Fulguration produces its effect by a coarse kind of mechanical superficial charring, while oscillatory current desiccation produces a refined, penetrating, devitalizing effect by drying, and possibly, some biologic effect in addition which I cannot at the present time define.

DISCUSSION

Dr. B. A. Thomas: It is true that good effects are obtained by this method in the treatment of papillomata of the genitourinary tract. In a case of papilloma of the bladder recently treated, the tumor has had but two applications of the current and shows improvement. In one case of papilloma of the rectum, ten days after a single treatment the papilloma could not be found.

Dr. William J. Dugan: In my opinion, we have no proof of this "oscillatory" movement, and nothing is shown that has not been known for years. It seems to me that we have no scientific facts. The Roentgen ray, radium and fulguration, I believe, are palliative, but I do not believe that they cure cancer or sarcoma. If, after a diagnosis of such condition by a good pathologist, the patient is cured I shall accept the facts.

Current Medical Literature

AMERICAN

Titles marked with an asterisk (*) are abstracted below.

Boston Medical and Surgical Journal

March 16

1 *The Lumbosacral Articulation. An Explanation of Many Cases of "Lumbago," "Sciatica" and Paraplegia. J. E. Goldthwait, Boston.
2 Diverticulitis of the Sigmoid. W. P. Graves, Boston.
3 A Series of Cases of Syphilis Treated by Salvarsan at the Walter Reed General Hospital, District of Columbia. H. W. Jones, U. S. Army.
4 Liquid Air in Surgery. T. C. Beebe, Boston.

1. **The Lumbosacral Articulation.**—An experience in connection with the treatment of a patient with a spinal lesion was so disastrous to the patient and so distressing to Goldthwait, that a series of investigations were started by him in the hope of bringing some relief to the patient, and at the same time of preventing such happenings in the future. When very tired from a long stress of work, in lifting a heavy object, the patient strained his back, producing a distinct displacement of the sacro-iliac joint on the right side. The condition was recognized at once, and under nitrous oxid anesthesia the bones were replaced without difficulty. This was followed by a fairly normal recovery, so that in about three months the subjective symptoms had largely disappeared. At that time, after a fairly long car journey, the man carried a very heavy suit case in one hand, without change, for a distance of over half a mile, with the result that the back became painful. Two days later he consulted Goldthwait because of pain and sensitiveness in the lower back. At that time the sacro-iliac joints were shown to be strained, but the bones were not displaced. The next night, in turning over in bed, he felt a distinct slip exactly similar in all its sensations to that felt at the time of the first displacement. In the morning, after having a restless night, he was able to get up and take his usual tub bath. On trying to get out of the tub, in leaning forward and straining to get up, something slipped in his back, entirely different from anything he had before experienced. The body was drawn forward and to the left; there was intense pain, so that it was with great difficulty that he was able to get back to his roo
and the suffering continued until he was seen by Goldthw

four hours later. At that time the body was held bent forward and to the left. There was extreme tenderness in the sacral region, with pain extending into the legs, the right being much worse than the left. All efforts to give the patient relief failed. The more the case was studied, the more it seemed that some mechanical element must be the real difficulty, and that the point of pressure was probably somewhere below the giving off of the lumbosacral cord, although not much below this because all of the nerves making up the cauda equina below this point were involved. It was obviously spinal, since no lesion or involvement of the nerve roots or of the sacro-iliac joints could explain so complete a bilateral condition. The more the case was studied, the more definite the lumbosacral articulation seemed to represent the seat of the difficulty, and this was strengthened by the fact that when the patient was placed on his back to have the jacket applied a few days after a laminectomy there was something of the same sensation that was present when the first jacket was applied, and this was at once relieved by raising the buttocks. A similar sensation also developed when he was placed on the back to have a skiagraph taken.

This led Goldthwait to make a very careful and thorough study of the mechanics and anatomy of the lumbosacral articulation. He found that the lumbosacral articulation varies greatly in its stability, depending on peculiarities in the formation of the articular processes and of the transverse processes; that these peculiarities not only result in less than the normal strength of the joint, but may represent mechanical elements, which not only produce strain and cause pain, but may lead to such great instability that actual displacement of the bones may result, with at the same time the separation of the posterior portion of the intervertebral disk. In such displacement, if the fifth lumbar vertebra slides forward on the sacrum, spondylolisthesis, the condition is usually compensated for, and pressure on the cauda equina or the nerve roots does not occur. If the displacement be on one side, the spine must be rotated and the articular process of the fifth drawn into the spinal canal with such narrowing that paraplegia may result, or the crowding backward of the intervertebral disk alone may be so great as to cause similar paraplegia, but of more gradual development. Weakness of the joints or the partial displacements may cause irritation of the nerves inside or outside of the canal and produce the bilateral leg pains often called sciatica.

24. **Mercury in Tuberculosis.**—During the past three years Wright has reported several hundred cases of chronic tuberculosis successfully treated by this method; among them were exhibited local lesions of practically all the organs and tissues, excepting the brain. He believes that the cases reported by himself and others demonstrate the fact that tubercle bacilli have a strong affinity for the succinimid and bichlorid of mercury. He has reported a number of cases in which three or four injections of one or the other of these salts caused the tubercle bacilli to disappear from the sputum and feces, and the cessation of the most profound toxemia. He now reports a case of acute miliary tuberculosis treated in this manner, which terminated in recovery and apparent cure, and which, in his opinion, emphatically and unquestionably demonstrates the parasitotropic and antitoxic properties of mercury in relation to tuberculosis. In less than eight weeks after the onset of the disease, at a time when 95 per cent. of these patients are either dead or dying, and six weeks after the administration of the first injection, the patient, a seaman, resumed his full duties on board ship, apparently cured. This result prompts Wright to say that in mercury we have the chemical affinity of the tubercle bacillus, and he expresses the hope that experimentation will sooner or later develop a command of mercury for which these organisms will have even a stronger affinity than they display for the succinimid.

26. **Gall-Stones and Cancer.**—This report is based on a study of over 9,000 post-mortem records in the Philadelphia General Hospital. In the report McGlinn has included cancer of the liver, pancreas and duodenum, on account of their close relationship to the biliary passages. In all, there are records of 456 cases of cancer. The liver was the site of primary cancer in twenty-six cases. Gall-stones were present in the gall-bladder in three cases and in the cystic duct in one case. The pancreas was the site of primary cancer in thirty-six cases. Gall-stones were present in the gall-bladder in four cases and in the gall-bladder and all the bile-ducts in one case. Gall-stones, then, were present in eight of the eleven cases of primary cancer of the gall-bladder. In primary cancer of the bile-ducts stones were present in three of the five cases. In the entire series of over 9,000 post-mortem examinations gall-stones were found in 507 cases. Studying these few cases, McGlinn says, it would seem that gall-stones play an important part in the etiology of cancer of the gall-bladder and bile-ducts, but in cancer of the liver and pancreas they are only incidental. They occurred no more frequently in cancer of these two organs than in cancer of more remote organs. There was a record of but one case of cancer of the duodenum; stones were not present.

27. **Irrigation in Septic Abortion.**—Weil urges continuous or frequent irrigations on the basis that absorption from the lochia is an important factor in the production of the toxemic element of puerperal sepsis.

29. **Pneumothorax.**—In the case cited by Beardsley, the onset of an acute pneumothorax caused violent abdominal symptoms which closely simulated those of perforative peritonitis.

41. **Relief of Glaucoma.**—During the past year and a half, Thomas has been using subconjunctival injections of sodium citrate to reduce the tension. Its use was suggested by the antagonism discovered to exist between the effect of acids and neutral salts on the imbibition of water by colloids. The method consists in the injection of from 5 to 15 drops of a 4.05 per cent. to a 5.41 per cent. solution of the chemically pure crystallized sodium citrate, preceded by the instillation of a cocain and an adrenalin solution into the conjunctival sac. During this time he has treated nine cases of primary and two of secondary glaucoma; all but one occurred in women. As a group, the primary cases were in individuals over the age of 45, and concerned thin, ill-nourished women of sedentary habits. The effect of these injections in reducing tension was unfailing and without evil consequences. After each injection there was a relief of the symptoms of glaucoma for from three days to several weeks. Thomas believes that the advantages of the subconjunctival sodium citrate injections over the other recognized surgical or medical procedures are evidently to be sought in their simplicity and in the promptness with which they produce results. Clearly these injections do not constitute a "cure" for glaucoma, but no more do iridectomies, sclerotomies or any other procedures which merely aim to reduce tension.

2. **Operative Treatment of Fractures of Neck of Femur.**—technic of the operation followed by Hunkin is described lows: The patient is placed on the back with each leg protected and wrapped separately. The assistant marks the line of the femoral artery just below Poupart's ligament. A cres .t incision from 9 to 15 cm. in length, depending on the of the patient, is swept from the anterior superior this incision reaches the muscular layer. In fat subjects ision divides a little of the rectus femoris and sartorius. In thinner subjects the muscle is not divided by reason of the incision being shorter. A few strokes of a dry dissector and the pulling inward of the sartorius brings one at once on the capsule of the hip joint. A little rotation of the leg, with a finger on the capsule, locates the anatomy and demonstrates the fracture. The capsule is then opened with a knife and the fragments are exposed. A pair of deep retractors are introduced when direct observation of the fragments can be made. The internal fragment can be rotated with the hand or with a dry dissector and the cartilage of the head observed. The external fragment moves, of course, with the leg. The leg is then manipulated until the fractured ends are in contact and placed in that position, whatever it may be in which they appear less likely to slip. In recent fractures this is usually in the extreme abducted position of Whitman. One assistant is now given the sole duty of maintaining this corrected position, and the parts are fully exposed so that the assistant can see the anatomic landmarks of the pelvis.

A tiny puncture with a bistoury is then made over the trochanter, from 4 to 5 cm. below the tip, into the bone, and a steel (sometimes silver-plated) nail, 8 cm. long, is driven through the trochanter and neck into the head. When the small head of the nail approaches the skin a steel "set," cupped to fit the head of the nail, is applied to the nail, which is driven firmly home. After the nail is located Hunkin often drives one of his staples across the line of fracture, the inner arm going into the head just at the cartilage rim, and the outer arm into the neck to the outer side of the fracture. The capsule is then closed as tight as possible with firm catgut and the wound closed in the usual manner. A plaster-of-Paris spica is then closely applied from toes to mammary line, during the setting of which firm pressure is made downward and forward from above and behind the trochanter.

60. **Poisoning from Datura Alba Seeds.**—In Manila and other parts of the Philippines the plant *Datura alba* (Nees) grows in great abundance, and from this plant hyoscin may be obtained in large quantities. The alkaloid is found in all parts of the plant, but in greater amount in the seeds than elsewhere. One of the chemists employed in the Bureau of Science of Manila, while conducting experiments with *Datura alba*, ate approximately a gram of the seeds. He probably took in all 5 milligrams of the alkaloid, and because of the severity of the symptoms produced his case is reported. After half an hour he noticed that his mouth seemed dry and in an hour felt somewhat flushed and noticed that his pulse was rapid. When Bowman saw him an hour later the pupils were widely dilated, he was nervous and restless and laughed most of the time. His face was flushed, pulse rapid—130 a minute. His speech was scanning in character and he was unable to make connected sentences. Later he became drowsy and had hallucinations, and as the symptoms seemed to be becoming more severe, he was sent to the hospital. After arriving there he became very drowsy and was soon asleep. The skin was very dry, though micturition seemed to be excessive. He was given a hot pack and remained asleep until the next morning. On awakening, except for some weakness, he seemed to be quite well again. He still had some trouble in completing his sentences, and he remembered nothing that had happened after the commencement of his symptoms. This case of poisoning was severe, but not serious. In cases of poisoning, Bowman says, the stomach should be evacuated as soon as possible. Pilocarpin in large doses has been used with alleged good results, but it is necessary to give so much to counteract even small doses of alkaloids of the atropin series that its use as an antidote is questionable. Hot packs should be used in severe cases, and any respiratory or cardiac symptoms watched carefully and treated.

62. **Philippine Contact-Poisoning Plants.**—With the purpose of ascertaining the facts concerning the possibility of poisoning by the hairs of the leaf-sheaths of bamboo, the following experiment was made by Robinson. The bamboo was that known as cauayan quilling, a name which seems to be used only for *Bambusa vulgaris* Schrad; it is widely distributed in the tropics, both eastern and western, and had been cut the day before. About 10 a. m., August 11, numerous hairs were rubbed on the upper arm. By noon the skin was reddened around the place, but no pustules could be detected. In the afternoon this reddening disappeared, and there were bare traces of pustules. The first itching sensation was noticed about 10:30 p. m., but the pustules were still few and small. By the next morning they were fairly plentiful, but small, with the surrounding skin reddened, without evident sensation. This condition continued throughout that day and the next, with occasional slight itching hardly perceptible except

on rubbing. From August 14 to 17 there was a gradual decrease, the pustules being still evident, without itching, with slight yellowish discoloration of the skin; on the morning of August 18 they were at the limit of visability, and would not have been noticed if their history had not been known. The immediate incentive to the experiment was the finding of similar pustules on the hands, a day after gathering bamboo material. The pustules disappeared without treatment, after a comparatively short time. While the bamboo, then, may be considered poisonous, the effect is not severe, and should not lead to anxiety.

A definite test on the nettle-like plant, *Fleurya interrupta* (Linn.) Gaudich., showed that the stinging sensation was felt at once, becoming moderately severe. After about five minutes, pustules began to form, but the pain ceased about the same time. The pustules soon disappeared, without treatment.

A recent involuntary contact with *Laportea meyeniana* (Walp.) Warb., lipa or lipang calabao, while causing immediate pain, did not result in any development of pustules; this is in agreement with experiments of others, even in severe cases of stinging by this plant.

63. **Tetanus from "Fuentes."**—"*Fuente*" is a cure practiced by the arbolarios or unlicensed physicians in the Philippines on persons suffering from stubborn diseases, such as beriberi, tuberculosis, anemia, etc., which, they think, physicians have failed to cure. Llamas says that it is a common belief among the poor class of people (and of some of the middle class), especially in the provinces, that they are relieved from their long suffering by opening a "fuente," as they express it, either on the arm, thigh or leg. Undoubtedly, this custom also prevails in Manila, having probably been introduced from the provinces. To start the infection, a mixture of lime and Chinese soap, in the proportion of two to one, is made into a "bolita" (pill), the diameter of which varies from 0.5 to 1 cm. This pill is then placed on the fleshy, least vascular part, usually the arm or leg, and is held in place by a tight bandage for twenty-four hours, or until a blister is formed. Next day another "bolita" of the same size (made of garlic) is placed on the surface of the previously opened blister, the wound dressed as before and the dressing is not removed until pus is produced and a cavity formed. The same effect may be produced by burning the skin directly with a lighted cigarette. The cavity once formed, another "bolita," made of Chinese wax or betel nut, is put in and covered with a piece of Chinese blotting paper. A hole is made in the middle of the paper and a piece of banana leaf is put on next and loosely bandaged. By the pressure the cavity receives, it becomes so deep that the pill soon has a cavity large enough to hold it.

Each part of the dressing has its own purpose. The pill is to maintain constant pressure on the cavity and to prevent any healing. The Chinese blotting paper absorbs any secretion, the banana leaf protects the wound from becoming wet and the bandage keeps out the air. The wound is washed morning and afternoon with warm guava water or ordinary tepid water and the dressing is changed. It is supposed that the secretion removes the impurity of the blood which has caused the sickness. If the "fuente" fails to cause secretion, the sickness is said to be incurable; if the patient gets well, the "bolita" or "pelotilla" is removed and the wound treated as before until it heals. Last May, Llamas treated a case of tetanus which was contracted through a "fuente" in the right leg of a woman suffering from beriberi and anemia. He thinks that an investigation would show that many cases of tetanus originate from infection due to the application of "fuentes."

79. **Resistance of Certain Bacteria to Calcium Hypochlori**—On treating Mississippi River water even with large amoun of calcium hypochlorite, the authors found it impossible effect complete sterilization. The predominant organis remaining after treatment was found to be a spore-beari bacillus. Treatment of this organism in pure culture has de onstrated a great resistance of certain spore-forming bacte to this chemical, which may be one of the factors, if not t most important one, in the failure to produce complete ster ity, and is probably the cause of the later rise in bacter count after treatment in certain experiments. Results on t comparative treatment of *B. coli* and *B. typhosus* in pure c ture show, in a general way, that the sum total of amoun of calcium hypochlorite required to exterminate both organis is about the same, yet in the selection of individual cultu some variation in the amounts actually required is indicat The results further demonstrate in a general way that pendi the formulation of better technical methods we may contin to regard the presence or absence of colon bacillus in treat waters as the index of possible infection with, or freed from, the typhoid organism. The authors venture to expre the hope that investigations may soon be undertaken in th country or abroad, which will seek to determine the effect the variable factors responsible for variations in efficiency sterilization procedures in which hypochlorites are employed.

83. **Adams-Stokes' Syndrome.**—Two cases of heart-blo which came under the observation of Thayer and Peabo during the past year presented features of unusual interes Case 1.—A man of 53, with rather thickened arteries and slightly enlarged heart, with evidences of sclerosis at the aor ring (rough systolic murmur), showed: (1) Syncopal and co vulsive seizures, associated with bradycardia and marked irre ularity in the size and sequence of the beats. These occurr often in groups of three or more in rapid succession, follow by intermissions amounting sometimes to nearly or quite ha a minute in length. The auricular, which could often counted clearly in the neck, was usually 100 or above. Lo intermissions in the ventricular pulse were usually associat with long periods of apnea. No wholly satisfactory tracin were taken during paroxysms of this sort. Those which we

made suggest a complete dissociation. (2) Similar attacks, usually without convulsions, in which the ventricular beats occurred in groups of from two to three to ten, always at the same rate, and apparently following the same impulses as the auricular beats. These groups of beats were separated sometimes by intermissions amounting to as much as fifteen seconds. The auricular pulsations could usually be counted in the neck, and were sometimes as slow as 50. Sphygmographic tracings showed that these groups of beats consisted of a primary ventricular contraction, apparently automatic, which was succeeded shortly by a series of beats which followed the preceding auricular contractions after an a-c conduction time of approximately normal duration. During these groups of beats the auricular rate became progressively slower without lengthening of the conduction time, until finally the ventricular impulses stopped. The retardation of the auricular impulses continued during the next several auricular contractions, after which it became more rapid. Such attacks yielded on three occasions to the administration subcutaneously of atropin, gr. 1/60 (0.001 gm.). The auricular rate after atropin was slower than it was before, but more rapid than the rate of several slow beats at the time of onset of the periods of ventricular intermission. (3) Periods during which there was a fairly regular ventricular rhythm of about thirty to the minute with a rather rapid auricular rate (100 to 120). The tracings show an apparently complete auriculoventricular dissociation. One of these attacks failed to yield to atropin, gr. 1/30 (0.0021) given subcutaneously. (4) Periods during which intermission in the ventricular pulse occurred at varying intervals and lasted for varying periods of time, followed usually by an apparently spontaneous ventricular contraction, which was succeeded by one or more beats after a normal a-c conduction time. (5) Periods between these attacks in which the heart's action was regular, and the sphygmographic tracings revealed no abnormalities, the a-c interval remaining always normal. Although there have been seven or eight grave attacks of Adams-Stokes' syndrome in a year and a half, the patient is to-day in good condition.

CASE 2.—A man, aged 83, for three or four years had had dyspnea on exertion and attacks of giddiness and faintness in which he had fallen to the street. Following treatment with infusion of digitalis, but persisting for more than a month after its discontinuance, there occurred periods of bradycardia, during which the pulse was sometimes nearly regular at about 40 and at other times irregular. The pulsations of the auricles observed in the neck were more frequent than those of the ventricles. The auricular pulsations further manifested themselves by a slight audible sound and sometimes by a palpable and even visible impulse at the apex. The cardiosphygmographic tracings showed a regular auriculoventricular rhythm, with much-prolonged a-c time, amounting sometimes to almost 0.6 of a second. At times there is characteristic dropping out of ventricular beats, associated with progressive *prolongation* of the a-c period and failure of conduction. At other periods there is an attempt to set up a spontaneous ventricular rhythm at the rate of about 40, a rhythm, however, which is not quite regular because of an occasional precocious ventricular contraction due, apparently, to the passage of a stimulus through the auriculoventricular bundle. The administration of atropin, gr. 1/30 (0.0021 gm.), resulted in the complete disappearance of irregularity and the development of a regular auriculoventricular rhythm with prolonged a-c conduction time. Pressure on the vagus resulted in the dropping out sometimes of alternate and, occasionally, of two successive ventricular beats. There was slight slowing of the auricular rate, with no apparent modification of the a-c conduction time. On one occasion, the administration of atropin, gr. 1/30 (0.0021 gm.), was followed by rapid action of the heart with alternating pulse. A year after the termination of these studies the patient was seen again, with an apparently complete auriculoventricular dissociation, the ventricular rate, however, being about 40. The authors regard this case as a typical instance of disease of the bundle of His in a hypertrophied and dilated heart.

85. **The Opsonic Index in Pulmonary Tuberculosis.**—Pettit does not regard the opsonic index as being an accurate method of diagnosis of mixed infection in pulmonary tuberculosis.

87. **The Acidosis Index.**—The method devised by Hart depends on the intensity of the color developed by adding ferric chlorid to urine containing the acetone bodies (Gerhardt's reaction).

102. **Congenital Defect of Clavicle.**—Five or six days after the birth of McGraw's patient, the nurse noticed a slight swelling under the left ear. On examination this swelling seemed to be the sternocleido mastoid muscle in a state of constant contraction. Beneath this swelling and somewhat external to it there was a small knob, which proved to be a rudiment of the clavicle about 1 inch long. The outer end was attached to the acromion process of the scapula, and the small rounded prominence was freely movable. All the inner portion of the clavicle was missing. The shoulder could be drawn forward and inward to the median line, and the scapulæ projected behind. At this time it was thought that this bony knob or enlargement might be a beginning osteosarcoma. Dentition has been perfectly normal in every respect. At the age of 17 months a second radiogram was made and showed the clavicle absolutely perfect. This case is regarded as being of interest chiefly through its demonstration of the fact that there must be more than one center of ossification in the clavicle, and that the delay in development through some embryologic accident did not inhibit the subsequent growth of the center or centers forming the nucleus for the inner portion of the clavicle in the case cited. Careful inquiry has been made into the matter of heredity brought forward so *prominently in* the cases of Marie, Sherman and King, but with an absolutely negative result; neither was there association with rickets.

109. **Tetania Parathyreopriva.**—In Brown's case, the implantation of monkey parathyroids was the only measure which with any permanence put the patient in better condition. Finally, however, it became necessary to transplant human parathyroids. After this procedure, the patient's progress toward recovery was continued and uneventful.

112. Abstracted in The Journal, Jan. 7, 1911, p. 67.

114. **Removal of Skin-Fat Wedge.**—The value of removing wedges of skin and fat in patients who are not troubled with obesity, but simply and solely for getting rid of a part of the thickness of the abdominal wall and making the field of operation more accessible, is emphasized by Kelly. An oval or an elliptical transverse excision is made, cutting right down to the strong fascia overlying the rectus and the oblique muscles. All bleeding vessels ought to be tied carefully. When this piece of skin and fat is removed the operator then finds it much easier to open the abdominal wall and operate than in a similar case in which he has to retract this embarrassing mass of tissue as well. Kelly closes such a wound with a fine catgut suture, catching a distinct layer of fascia about the middle of the fat, the silkworm-gut sutures uniting both skin and fat.

117. **Empyema of the Ureter.**—Fowler's patient, a man, gave a history of calculous diseases of fifteen years' duration. The onset was marked by symptoms referable to the kidney. He had passed a great many calculi. Perineal section was performed for an impacted calculus in the urethra. Another stone was removed from the urethra by milking it forward to the meatus. Two litholapaxies were performed. The left kidney was removed on account of calculous pyonephrosis. Empyema of the left ureter developed as a result of the presence of a calculus, which was demonstrated in the first Roentgen-ray examination. This calculus was forgotten and consequently overlooked at the time of the left nephrectomy. Infection of the right kidney took place, pyonephrosis developed, and complete anuria occurred suddenly three years later. Anuria was complete for three days, and was due to the plugging of the ureter with pus. Renal retention was partially relieved by massage of the kidney and along the ureter, thus dislodging the plug of pus filling the ureter. Anuria again developed and nephrotomy of the remaining kidney was done. This kidney was greatly distended with urine and pus. No stone was demonstrated by the Roentgen ray and none was found at operation. The parenchyma formed a mere shell of tissue less than 1 cm. thick. Recovery was prompt and complete. Since the operation the patient has passed one stone and another has been removed from the bladder by litholapaxy. The skiagraph now shows a stone in the left ureter of the same shape, size and location as shown in the plate taken three years ago. Normal peristalsis was observed in this ureter three years after the complete removal of the corresponding kidney.

120. **Operation for Stiffening Knee-Joint.**—Hibbs believes that the knee-joint has not been stiffened frequently enough, especially among the classes of people seen in the dispensaries, who are, in most instances, wage-earners, and the necessity of wearing some kind of brace permanently is troublesome and expensive to them. This is probably due to the fact that attempting to stiffen this joint by the old method of doing practically an excision has not been very successful. In the first place, the removal of a sufficient amount of cartilage from the femur and tibia to secure bony surfaces for approximation shortens the leg about 1½ inches, which, with the shortening already present in these cases, is a serious consideration. And in the second place, the removal of the ligaments makes difficult the prevention of deformity during the long period, a year or more, before there is solid bony union. This led Hibbs, on Jan. 15, 1909, to perform an operation which obviates these disadvantages. It was that of mortising the patella, after it was denuded of its periosteum and cartilage, into a space prepared for it by the removal of the cartilage, just anterior to the center of the tibia and femur. Such a space may be secured without injury to the crucial ligaments or to the epiphysis of either bone. With the patella in this position, a perfect bony bridge is thus formed between the tibia and the femur. The patella in the first three cases was put in transversely, and in the next four horizontally. In all these cases, in from five t six months there was solid bony ankylosis, which has bee maintained a sufficient length of time since the removal of th support to consider it permanent.

It then occurred to Hibbs, that if the patella were place horizontally in a space prepared for it, and then if the perios teum were carefully preserved in its removal from the patell and brought down over the freshened area and stitched to th periosteum around the edges of the tibia and femur, ther would be reproduced from this periosteum new bone, so tha the bony bridge would be larger and stronger. In the last thre cases, this procedure has been adopted, and in each case ther has been a reproduction of bone from this periosteum, as ha been unmistakably shown by skiagraphs. The advantages o the latter procedure are obvious. In the first place, there i less likelihood of the patella slipping out of its bed, and i the second place, there is secured, through the reproduction c new bone, a larger and stronger bony ridge, and the weigh may be safely borne on the leg earlier with advantage, an all support removed sooner.

134. **Extra-Uterine and Intra-Uterine Pregnancy.**—Cente case was one of combined extra-uterine and intra-uterine pre nancy at the same time, with rupture and removal of tl extra-uterine pregnancy, and both tubes and both ovaries, tl intra-uterine gestation proceeding undisturbed to full term a normal labor.

137. **Phthisiophobia.**—The resident staff of the Cook Coun Hospital has been traced by Tice, and the frequency of tube culous infection determined as accurately as circumstanc will permit. During the period of thirty-three years, fro 1866 to 1909, 376 physicians have served as interns, and ea member, with the exception of the first three, has served period of eighteen months. Until within the last year and half, no attempt was made to segregate the tuberculo patients, but they were cared for in the general wards, n especially constructed for this class of patients, and whe no special precautions were enforced. Of the 376 members the resident staff, three had tuberculosis before their servi four during their service, and thirteen have developed it sin that time, making a total of twenty, of whom six have die Accepting the validity of the preceding statements, Tice thin it is evident that the danger of infection in tuberculosis h been overestimated and exaggerated. As a result, tuberculo

individuals and the public at large have been subjected to great inconvenience and hardship. The medical profession, he declares, should realize the evils of these misconceptions and endeavor to correct them so far as possible; physicians should no longer continue to repeat many of the current stereotyped statements on tuberculosis, but more nearly to approach the truth as indicated by knowledge of recent developments. The nursing profession should be instructed properly and trained in the care of the tuberculous. Since much of the fear of tuberculosis has resulted from the educational efforts of the various antituberculosis organizations, it becomes incumbent on them to continue their efforts and assist in diminishing this evil.

138. **Action of Iodin on Tissues.**—The main object of Werelius' research was to ascertain the action of iodin on the healing process of wounds. For this purpose, two wounds were inflicted on the back of dogs on each side of the spine, treating one with, and the other without, application of iodin. The wound treated with iodin always healed much more slowly than the wound not so treated. In the experiments tincture of iodin was used.

139. **The Theory of Hearing.**—Shambaugh believes that the membrana basilaris is physically incapable of performing the rôle of a vibrating mechanism, and, furthermore, that the membrana tectoria must be this mechanism. Just how the membrana tectoria responds to the impulse of sound waves is largely speculative since this is beyond possibility of actual demonstration. His conclusions regarding the manner in which the structure responds is arrived at by assuming that manner of response which best explains the various phenomena associated with sound perception both in the normal physiology of hearing and in the phenomena associated with diseases of the labyrinth.

144 Exposure to the Sun as an Etiologic Factor in Alopecia. G. F. Harding, Boston.

141. **Infectious Eczematoid Dermatitis.**—In observing a large number of cases of dermatitis, Fordyce has been struck by the frequency with which forms of skin infection, usually diagnosed as eczema, have been secondary to some antecedent lesion or disease of the skin, such as scabies, wounds or traumatisms which have become infected, abscesses, furuncles, intertrigos, sinuses left after operation on bones, etc. In other words, the percentage of eczemas which were not preceded by some antecedent pathologic condition seemed to be in the minority. At times, when the eczematous and pyogenic processes have coexisted, it has been difficult to determine which condition was the primary one. On the other hand, when eczema and furunculosis were coincident, it was learned, on making inquiry of the patient, that the furuncles had in many cases antedated the outbreak of eczema. In addition to cases resulting from a purulent discharge or skin infection, Fordyce has noted others in which one or more scaling patches of dermatitis present for an indefinite time suddenly assumed an acute inflammatory reaction and spread by continuity or independent foci to other parts of the body. He believes that those cases belong to the group described under the name of infectious eczematoid dermatitis, and that irritation of the skin produced by discharges from abscesses, sinuses, ulcers and other pus-secreting surfaces is the true basis of these phenomena. In certain of these cases, the outbreaks occur at a distance from the primary focus and are not to be explained on the ground of autoinoculation or direct conveyance of the irritant substance. These cases, Fordyce would claim to be due to anaphylaxis.

152 Does Dextrose Arise from Cellulose in Digestion? G. Lusk, New York.

149. **Influence of Cold Baths on Glycogen Content of Man.**—In order to determine whether cold baths will not completely remove the glycogen content of a man, two individuals who had accustomed themselves during the summer to a swim of fifteen minutes' duration in the early morning in cold water, and who took daily cold douches as a matter of routine at other times, submitted themselves in the morning (without breakfast) to the action of two baths, each of from six to ten minutes' duration. The water contained floating ice blocks and had a temperature of 10 C., the baths being given at intervals of about two hours. The treatment was effective in exhausting the glycogen supply. Lusk concludes that immersion of normal men in cold baths at a temperature of 10 C. when the intestine is free from carbohydrates, induces shivering which causes a rapid utilization of body glycogen as determined by a fall in the respiratory quotient to the fasting level. In one very muscular individual this result could not be obtained. In one individual in whom the shivering had been severe, a quotient of 0.67 and anotner of 0.62 were found during subsequent periods of rest, which correspond to those observed during rest after a period of exhaustive exercise (glycogen formation from protein). The greatest increase in heat production which was brought about by the cold baths was 181 per cent. above the normal. The urine remained free from albumin and from sugar.

151. **Effects of Various Forms of Exercise.**—The conclusions to be drawn from Lowsley's experiments are as follows: All types of prolonged exercise which cause an increase in pulse rate cause also a rise in systolic and diastolic pressures. The systolic pressure shows the greater rise; hence there is an increase in pulse pressure, which may be interpreted to mean that the heart beats are augmented as well as accelerated. After all types of exercise studied, the systolic, diastolic and pulse pressures invariably fall below normal and remain in this subnormal condition for a considerable time. The more exhaustive the nature of the exercise, the longer will be the subnormal period which follows. Systolic pressure invariably falls more rapidly than diastolic, and hence the pulse pressure becomes weaker. Pulse rate, which always increases during exercise, decreases rapidly after its completion. Rapid exercises (vigorous, fatiguing and exhausting) are followed by a fall of pressure below normal which lasts longer than after moderate exercise, even if the former is continued only for a very short period and the latter for quite a long period of time. If Lusk's interpretation of the subnormal phase is correct, it would follow that the so-called field events, consisting of jumping, shot putting, discus and hammer throwing and baseball, gymnasium apparatus work, and exercises of a similar nature, are preferable to rapid exercises such as basketball, football and running races. This is particularly true in the case of the rapidly growing youth, whose heart is under the additional demand of keeping pace with an increase in the tissue mass of the body. There is less strain put on the circulatory system by walking a number of miles at a moderate rate than by sprinting 100 yards at top speed. Long-distance races and similar forms of exhaustive exercise give rise to a serious strain on the heart, as is indicated by the long period of subnormal blood-pressure.

162. **New Technic in Use of Forceps.**—The indications for the technic described by Swiney are: Vertex presentations, or convertible vertex presentations with no engagement, when there is no great disparity between head and inlet. The principal points in the method are the Walcher position, forceps application at the beginning of a pain and withholding the anesthetic until the head is properly forced into the brim. This plan should not be tried until the os is fully dilated and sufficient time should always be given for Nature to do her best. In using the Walcher position, the toes should not touch a chair or the floor during a pain. An assistant must hold the patient by the shoulders to keep her on the table. During the interval an assistant should hold up her legs, as it is more comfortable for the patient.

1. **Mediastinal Affections.**—Nine cases are reported by Kidd: Case 1. Substernal thyroid tumor simulating a mediastinal new growth; operation, recovery. Case 2. Mediastinal cyst (? dermoid); operation; recovery. Case 3. Mediastinal abscess perforating the trachea and esophagus and causing subcutaneous emphysema and cellulitis; temporary relief following bleeding; death. At the necropsy the left pleura was found to contain 1½ pints of brownish turbid fluid, the lung being collapsed and covered with recent greenish lymph. Both lungs contained numerous miliary abscesses. In the esophagus opposite the bifurcation of the trachea there was a flat oval fibroma measuring 1x⅔ inch, and just to the left of the tumor a small smooth-edged opening led into an abscess cavity at the bifurcation of the trachea. There was also acute recent pericarditis. The disease appeared to have originated in the subtracheal lymphatic glands, whether as the result of tuberculosis or some other cause could not be determined. Case 4. Mediastinal growth masked by pericardial effusion; death. At necropsy the mediastinal glands in front of the trachea and bronchi were found to be infiltrated with a firm whitish-yellow growth forming a mass of about the size of a duck's egg, not occluding or narrowing either bronchus, trachea or esophagus. There was a small nodule of growth in the upper lobe of the left lung. Case 5. Mediastinal growth masked by pleural effusion; death. At necropsy a large pleural effusion was found on the right side and turbid fluid with flakes of lymph. The trachea and the root of each lung were embedded in a large whitish growth extending widely into the lower lobe of the right lung. The esophagus and large veins were not involved. Case 6. Tuberculosis of mediastinal glands followed by pleurisy with effusion; recovery for some years; death from tuberculous meningitis. Case 7. Tuberculosis of mediastinal glands compressing the right bronchus; recovery. Case 8. Tuberculosis of mediastinal glands involving the lung by direct infection through the bronchi. The case progressed slowly downward, the chief features being remittent pyrexia, loss of flesh and slight cough. Signs of consolidation gradually spread up toward the apex of the right lung, râles and rhonchi appeare over both lungs, and the patient died from tuberculous meningitis. At necropsy large caseous glands were found in the anterior mediastinum and beneath the fork of the trachea The right bronchus was perforated by the caseous glands in two of its divisions—the branch to the middle ear and the branch to the lower lobe. The middle lobe of the right lung was converted into a large caseous mass. In the upper lobe there were a limited fibrosis and a small cavity. Both lung were studded with miliary tubercles. There was tuberculou meningitis. Case 9. Tuberculous abscess of bronchial glands bronchopneumonia simulating acute tuberculosis; death from septicemia.

To determine whether bronchial breathing, like bronchophony, is heard about the seventh cervical, and three or fou dorsal upper vertebræ in a great number of healthy persons especially in those that are thin, in women and children Kidd examined fifty-one patients consecutively. The only patients excluded were such as had consolidation of the lung of any kind, pleural effusion, or any evidence of tuberculou or other glandular disease in any district of the body. O these fifty-one patients, thirty-three showed bronchial breathing or pectoriloquy over the seventh cervical and upper dorsa spines, usually the first and second. In twenty-two cases both bronchial breathing and pectoriloquy were present; in eleven cases either bronchial breathing or pectoriloquy alone. In eighteen cases the results were uncertain or negative. Mos of the patients who gave positive results were spare or thin but not all, a notable exception being a man weighing ove 210 pounds, the subject of a cerebral tumor. Among the positive cases nineteen were male and fourteen female; age: unde 10 years, seven cases; 10 years and over, twenty-six cases Kidd feels persuaded that we may expect to find bronchia breathing and pectoriloquy over the upper dorsal spines in many healthy people.

3. **Mechanical Treatment of Spinal Caries.**—Gauvain discusses mechanical treatment during recumbency only.

5. **Suprarenal Apoplexy.**—The history of Waterhouse' patient, a boy aged 8 months, was as follows: throughout the morning the child had been very drowsy and had "looke strange," but had not seemed to be in pain; he had take nourishment readily, and the bowels had acted as usual. Abou 3 o'clock in the afternoon he vomited. Previously the chil had always seemed perfectly healthy. He had been breast-fe until three weeks before admission, when a mixture of cow' milk and water was substituted. The infant was obviousl very ill: complexion gray, eyes dull, breathing rapid, shallow and noiseless; temperature 100.4 F., pulse 140, and respirations 72. Râles could be heard all over the chest, especially at the bases behind. The abdomen was soft and not tender There were no signs of meningitis, and nothing abnormal wa to be seen in the mouth or fauces. Two hours after admission an extensive eruption of purple spots and blotches appeared over the whole trunk, upper arms and thighs. The temperature had fallen to 99.4 F. The child rapidly grew worse, the face became cyanosed, and death occurred four hours afte admission. There were no convulsions throughout.

The post-mortem examination was made twenty-two hour later. The suprarenal capsules were striking objects even before their removal from the body; of little more than norma size for a child of this age, they were both of a deep purple color and evidently the seat of hemorrhage. The extravasation of blood had taken place into both the cortical and medullary portions, but no bleeding had occurred into the adjacent tissues. Microscopically, the structure of the medulla was seen to be completely destroyed and replaced by effused blood. The arrangement of the columns of cells in the cortex could be made out, but the cells themselves had largely disappeared, their nuclei alone remaining, while everywhere were to be seen large numbers of red corpuscles. All the other organs appeared natural. Cultures taken from the adrenals, from the spleen and from the cerebrospinal fluid all proved sterile. No microorganisms could be detected in films made from the cerebrospinal fluid and from the interior of the suprarenal capsules.

16. **Presystolic Murmur.**—The presystolic murmur consists of a series of sounds following each other in rapid sequence, the murmur being sometimes short and at other times prolonged. When short, it resembles a reduplicated second sound at the apex; on the other hand, it may occupy the whole of a prolonged diastolic period, being frequently a half a second or even a full second in duration. Cardiograms taken by Gill show, he says, that the vibrations, which when palpable form the thrill, are really continuous during the whole cardiac cycle, and are always present, whether the presystolic murmur be audible or not. These vibrations are often best obtained from an area well over the right ventricle—that is, internal to the nipple line, a little above the level of the nipple. They vary in rate as a rule from about seven or eight a second to ten or twelve, and can be recorded in a variety of pathologic conditions apart from mitral stenosis, and are therefore not peculiar to it. Although these rapid movements are frequently encountered in cardiograms, yet in venous pulse records they are only occasionally present. In jugular tracings from cases showing a continuously irregular pulse, they are often well marked during long diastolic pauses and are now generally recognized as being due to fibrillary contractions of the auricle. They can often be obtained in cardiograms from these cases.

The presystolic murmur is not, Gill says, necessarily dependent on contraction of the auricles. It is occasionally associated with an irregular pulse. The right auricle is the seat of regularly occurring vibrations, yet there is no proper contraction as shown by the venous pulse; the left auricle, as shown by the presystolic murmur and the apex tracings, shows similar movements; the ventricular contraction is continuously irregular. Research by means of the string galvanometer, has shown clearly that in all cases of persistent irregularity similar vibrations are always present; these vibrations have therefore undoubtedly a muscular origin, and further arise in the right auricle. The string galvanometer shows usually in cases with presystolic murmur, a double-peaked wave; sometimes the wave has three peaks, at other times four. The explanation is that these waves are due to independent contractions of the sinus venosus tissue in the right auricle, and to a much less degree in the left auricle. In the course of development the two auricles absorb the sinus venosus. It is still uncertain what part of the auricles is derived from the sinus venosus; in the right auricle, probably that portion lying between the mouth of the superior vena cava above and the inferior vena cava and coronary sinus below, together with the adjacent part of the inter-auricular septum; in the left auricle the opening of the pulmonary veins, which have been observed occasionally to be capable of independent muscular contraction. We thus have a perfectly simple explanation of the presystolic and other diastolic apex murmurs. Vibrations occurring in the left auricle are rendered audible at the apex, by the fact that the blood in the auricle is under tension; the movement of the blood transmits these audible vibrations to the apex.

Gill points out that any explanation of the presystolic murmur must explain its proper relation to contraction of the left auricle. There is no doubt of the almost absolute association of contraction of the left auricle and the presystolic murmur, but there are a few exceptions. Such exceptions show that contraction of the auricle properly so called is not essential to the production of the presystolic murmur. The explanation seems to be that the sinus venosus movements involve only a small part of the muscular wall of the left auricle particularly; hence, a certain degree of tension being necessary for the production of sonorous vibrations, these movements are lost in the flaccid membrane, till the contraction of the auricle proper commences. The necessary degree of tension in the auricular wall may be present when the muscular tissue of the auricle is good, the obstruction being yet considerable: in that case, the auricular wall would be in a constant state of tension. Gill has seen three such cases in three years.

18. **Identification of Bacillus Typhosus and Bacillus Dysenteriæ.**—For the differentiation of these bacteria, Bradley uses plates of simple agar. Next day a number of colonies, at least ten, if possible from twenty-five to fifty, are picked off from the plate directly into lactose litmus peptone water. Next day those tubes showing an acid reaction are thrown out, leaving only the non-lactose-fermenting orgahisms. Some (at least six) and preferably all of these are then inoculated into mannitol litmus peptone water, saccharose litmus peptone water, sorbitol litmus peptone water, litmus milk, peptone water and gelatin, and films are made and stained by Gram's method. If next day any cultures, which by films are shown to be Gram-negative bacilli, give acid on mannitol and sorbitol and *nil* on saccharose and slight acidity on litmus milk, the agglutination reaction of one or more may be tested. If this be positive, in a dilution approaching the titre of the serum for control standard culture, the provisional diagnosis of *B. typhosus* may be made, but a week at least should be given before the diagnosis can be certain, after which the milk should remain very slightly acid and not clotted; the peptone water should become turbid and give no indol reaction, and the gelatin remain unliquefied.

For most practical purposes, Bradley believes that the following is a sufficiently good definition of typical *B. typhosus:* a Gram-negative bacillus, non-gelatin liquefier in seven days, non-lactose fermenter, non-saccharose fermenter, giving acid (without gas) on mannitol and sorbitol, very slight permanent acid without clot on litmus milk, and no indol reaction on peptone water in seven days. If these characteristics are all presented, Bradley has no hesitation in pronouncing the organism *B. typhosus.*

20. **Treatment of Incipient Phthisis by Tuberculin.**—Ure reports most encouraging results from the use of Koch's old tuberculin, commencing with very small doses and gradually increasing until extraordinary toleration to the toxin is established, active immunization being at the same time produced, which induces steady improvement in the patient's condition.

24 *A Case of Myasthenia Gravis. T. G. Moorhead.
25 *Epidemic Pneumonia. A. J. Powell.
26 Congenital Fistulas. J. H. P. Boyd Barrett.
27 Influenza. J. F. Clarke.

24. **Myasthenia Gravis.**—The essential symptoms of myasthenia gravis consist of paralysis of the voluntary muscles, more especially those supplied by the cranial nerves, varying in intensity and persistence, but usually more marked after muscular effort, and accompanied by a peculiar myasthenic reaction when the muscles are stimulated by the faradic current. Among the most common paralyses are those of the

ocular muscles, including the orbicularis palpebrarum and the levator of the upper eyelid, the lip muscles, those of the tongue and those of the neck; but in severe cases almost all of the muscles of the body may be involved. The paralysis almost invariably tends to increase when the affected muscles are used, so that at the beginning of a conversation the lip and tongue muscles may be used fairly well, but after a few minutes they become weakened, and soon may become so completely paralyzed as to be hardly capable of being made to contract at all. The appearance presented by the patient is strongly suggestive of the existence of some lesion of the nervous system. Moorhead's patient, on the eleventh day, was attacked with sudden dyspnea and cardiac failure, became quite unable to speak or swallow, and died in a couple of hours. The case was typical; however, there was marked atrophy of the gluteal muscles, the deltoids, and of the tongue, inasmuch as absence of atrophy was at one time regarded as an important diagnostic sign.

The post-mortem findings in this case were as follows: the thymus was persistent, and possessed two well-defined lobes extending down over the pericardium; microscopically it was normal, but contained no eosinophil cells. The thyroid was somewhat enlarged, and microscopically was more cellular than normal. The kidney was slightly congested and showed parenchymatous changes; both ovaries were enlarged and cystic. The other viscera, including the red marrow and pituitary body, were normal microscopically and macroscopically. The spinal cord, the medulla, the pons, the central nuclei and the cortex in the Rolandic region of the brain were normal. Macroscopically, the brain and spinal cord were normal. As regards the muscles, sections were made from the levator palpebræ superioris, the masseter and the pectoralis major, and in all Moorhead examined over 400 sections. The masseter and pectoralis major appeared to be normal, with the exception of one doubtful lymphorrhage in the pectoralis. The collection of cells, however, in this particular instance was found not between the muscle fibers but in the interstitial connective tissue. In the levator palpebræ some atrophy of muscle fibers was noted, marked proliferation of sarcolemmal nuclei was present, and in many of the sections scattered uninuclear cells with rounded nuclei were found between the muscle fibers. Nothing at all approaching in appearance, however, to the lymphorrhage, as figured by Buzzard, was found, and after a most careful search in three of the muscles of a very typical case, Moorhead feels inclined to throw doubt on the universal presence of lymphorrhages in the muscles of myasthenic cases.

25. **Epidemic Pneumonia.**—This epidemic recorded by Powell occurred in April and May, 1909, in the village of Penn, near Wolverhampton, Staffordshire, England. The patients came from the smaller cottagers in the village with the exception of the first, who came from about one mile outside the village. The number of recorded cases was nine. The number of deaths was seven. The cases can be divided into two series, in each of which a clear history of direct infection from case to case was manifest. In the first group there were four cases and in the second three. The remaining two occurred sporadically, but were both attended by the district nurse who had attended some of the other cases. Beyond these significant facts no clearer history of infection could be obtained in the last two cases. The type of disease was characterized by great cardiac depression, cyanosis and dyspnea at the outset with but few local physical signs. The number of cases attended by other practitioners in the immediate neighborhood during this time was considerable, but accurate information cannot be obtained either as to their numbers or the type of the disease or the nature of the infection. Only two of Powell's patients recovered, both children, one aged 14, the other 6. All the adults died, making a mortality of 77.7 per cent.

29 Recent Advances in Hematology. W. K. Hunter.
30 *An Unusual Complication of Measles. A. J. Couper.

30. **Unusual Complication of Measles.**—In Couper's case a fairly well-marked and typical measles eruption was present, and involved the whole skin area. Coryza and conjunctival suffusion were mild. The patient was a well nourished chil but flabby. The heart sounds were soft. Pulse was of lo tension. Mucous râles were present, and were heard over bot lungs, anteriorly and posteriorly. These were most numero and were of finer quality at the right base behind. No dulne was detected, and the respiratory murmur was nowhe impaired. The case ran the usual course. The rash becan brighter and the temperature rose on the fifth day of illnes the former began to fade on the ninth day of illness. Wi the fading of the rash, the temperature rose to 102 F., whi pulse and respirations numbered 140 and 60 respectivel From this somewhat high register there was a drop of tempe ature, which occupied three days, the temperature being n mal on the twelfth day. During this period there was alteration in the chest condition. On the sixteenth day, t temperature again rose to 102 F. This was accompanied an increase in pulse-rate to 136, and in respiration-rate to Next day temperature was 97.6 F. The dorsum of the rig hand was found to be swollen and edematous. Circulation the part was good, and there was no discoloration. No p or tenderness was present in any part of the limb. On t following day the swelling was much increased, involving t palm and extending up the wrist. The terminal phalanx each digit had become cyanosed, and the circulation in t fingers was very sluggish. By the nineteenth day the swelli had become pronounced. The whole of the right arm, toget with the inner wall of the axilla, was affected, and these pa were distinctly edematous and very tense. The limb was c to the touch and mottled (of a purplish color), while extremities of the digits were black. With this increase swelling, temperature rose to 103 F.; pulse, 138; respiratio 40. Crepitant râles were heard at both bases posteriorly, no dulness was detected. On the twentieth day the swell was still further increased, the limb and the inner wall of axilla had assumed a much deeper and more uniform tint, numerous ecchymoses and bullæ, containing a sero-sangui lent fluid, were observed. The child died on the twenty-fi day of his illness. Two days after death a post-mortem exa ination was made. In the subclavian vein, about half an i from its proximal extremity, was a firm clot, which exten for an inch backward, and was adherent to the wall of vein. Attempts to grow cultures from the clot failed.

45 Verrucous Tuberculosis of Leg After Lesion of Metatarsus. A. Trèves and G. Schriber.

40. **Insufficiently Fed Nursing Infants.**—Nagcotte confirms Merklen's statements (mentioned in these columns March 4, ᵕe 702), that mothers often take too literally the directions of their medical attendants in respect to overfeeding their children and go to the other extreme. This is particularly the case, she has found, among the young mothers in the student quarter of Paris, progressive women, solicitous for the welfare of their infants, whom yet they are scientifically starving. These women are not so good nurses, to begin with, as the less nervous women of the uneducated classes. She remarks that this hypoalimentation is an artificial vice, of exclusively medical origin, and the babies are all against it, so that it can soon be suppressed if its presence is once recognized. The trouble is that when the infant vomits repeatedly, this being a characteristic symptom of the lack of sufficient nourishment, the tendency is to reduce the ration still lower. Another characteristic sign of insufficient nourishment is that the infants try to put both hands in the mouth and suck the fingers hungrily. All this, she remarks, teaches anew that medicine cannot be reduced to mathematical formulas; rules valuable for full-breasted, robust women cannot apply to frail nervous women more or less exhausted by privation and study.

[G. Variot reiterates that the signs of overfeeding and of insufficient feeding frequently have features in common, especially repeated vomiting and distended abdomen. It would be a great mistake, he emphasizes in a recent communication on the subject published in the *Bulletins de la Soc. Méd. des Hôp.*, to regard big-bellied infants as necessarily always overfed; frequently the abdominal ectasia, as he prefers to call it, is the result of swallowing of air as the child sucks in its vain effort to obtain enough nourishment. There is generally a marked disproportion between the size and the weight of such underfed children, and the Roentgen rays may show the distention of stomach and intestines with air. The little body floats lightly on the surface of water if the head is sustained with one finger. When the children are given sufficient nourishment the abdomen promptly subsides to the normal aspect.]

42. **Test for Age of Milk.**—A colored plate shows a color reaction obtained with milk too old to be sanitary for infants. The technic for the test is rapid and simple. Two stains are required: a 1 to 4,000 solution made by dissolving 0.25 gm. of methylene blue in 1 liter of distilled water; and a second solution made by dissolving 0.25 gm. of fuchsin rubein in 50 c.c. of alcohol and then diluting to 1 liter. To about 20 c.c. of the milk to be examined are added 3 drops of the fuchsin solution and 5 drops of the blue solution. The test-tube is plugged with cotton and placed in water in the water-bath and heated to about 38 or 40 C. The color gradually changes om the first ash-grey tint to a lavender and then to pink, rom decoloration of the blue. The change of tint occurs the more rapidly the older the milk; if the change occurs in fifteen minutes the milk is too old to use; if the color reaction occurs in three quarters or an hour, the milk is too old for infants and the sick, and the milk should be *regarded as suspicious* when the change of tint is observed in less than an hour and a half. The test is based on the *presence of reductase* in the milk, the reductase being the consequence of the development of microorganisms. Negative findings may not be conclusive, the authors state, but positive findings *may* be relied on.

43. **Criteria of Normal Stools.**—Triboulet has long been insisting that simple inspection of infants' stools is inadequate for proper estimation of conditions, while comparison of the explana with the acetic-acid test gives an instructive over- action the digestive functioning. With a normal stool, the to a m of the test-tube form a homogeneous mixture, developn the top and becoming turbid toward the bottom, is still n being of a peach-flower pink. When digestion is grained sediment settles to the bottom float on top. The litmus reaction should or breast-fed infants and alkaline stools he presence of bile salts is indicated by an immediate red tint in the Pettenkofer test, while the bile pigments under four months show in the green meconium; after four months the stercobilin shows pink; the control test is the fluorescence with zinc acetate. Salts, lactose, casein and fats are not discoverable in normal stools on milk alone, and starch is all digested. Whatever the diet, there should be no red or pink reaction with phenolphthalein as these indicate the presence of blood or of products of fermentation. The acetic sublimate test is made by treating the well-diluted stool, for macroscopic examination, with 8 or 10 drops of the ordinary laboratory solution of 100 c.c. distilled water; 3.5 gm. of bichlorid of mercury, and 1 gm. of acetic acid. About 10 drops of this mixture are added to the diluted stool in a test-tube and the color findings are examined after one hour or up to twenty-four hours at most. Triboulet uses a printed chart to record the findings with the acetic test, in addition to the age, clinical diagnosis, diet, aspect and frequency of the stools, their consistence, odor, color, reaction and the findings with the Pettenkofer, biuret, Lugol and phenolphthalein tests—all the latter tests are negative with normal stools.

47. **Review of Scopolamin in Obstetrics.**—The scopolamin-morphin method of anesthesia for painless labor was originated by Steinbüchel, Lequeux remarks, but Krönig was its apostle and Gauss has been its executive, while Hocheisen denounces it as dangerous for both mother and child, and several other prominent obstetricians share this view. All acknowledge that the method has varying effects, that cases of inexplicable idiosyncrasy are sometimes encountered, and that the same technic is very liable to give very different results in different patients. The work of thirty-one writers on the subject are reviewed. The total number of cases in which it has been applied is 4,619, and this material is tabulated for comparison, showing the percentage of good and bad results for mother and child. Lequeux' final conclusion is that we may feel encouraged to continue cautious clinical research on the subject.

52 *Treatment of Dread of Emotional Blushing. (La base organique de l'éreuthophobie et son traitement.) P. Hartenberg.
53 Immobilization in Tuberculous Osteo-Arthritis. G. Monod.

48. **Slight Dilatation of the Bronchi in Children.**—In children, mild forms of bronchiectasia may exist which seldom cause symptoms; weeks and months may pass before any functional disturbances can be observed. The bronchiectasia thus escapes detection until some casual infection of the air passages above extends to the dilated bronchial tubes. General symptoms then rapidly develop, sometimes serious, with peribronchial and pulmonary disturbances and signs as of cavity formations. These local phenomena may prove misleading, but correctly interpreted they clear up the diagnosis. The fever is often high, with a wide range, the pulse rapid, and there may be a distressing cough, especially when the temperature runs up. The sputum is purulent but not fetid as in adults, and the dyspnea is generally moderate. The chest may be retracted on one side and the wall less movable, with impaired resonance or actual dulness over the lesion. In the intervals between the exacerbations of the catarrh the râles may subside, but the cough arouses them again. The younger the child the greater the chance of recovery; but every catarrhal affection retards this and increases the tendency to sclerosis of the lungs. Such children should be guarded carefully and particularly shielded from contact with tuberculosis. Differentiation from established tuberculosis is often difficult, but the overrapid development of signs of a

cavity, their location at the base of the lung and absence of tubercle bacilli in the sputum, together with the antecedents should suggest the bronchiectasia.

51. **Meningitis and Tabes.**—Tinel shows in thirteen illustrations the changes in the nerve fibers in the course of any meningitis. The radicular meningitis is seen to be practically the same process in the various infections, tuberculous, cerebrospinal, syphilitic, etc. Ordinary meningitis either speedily heals or progresses to a fatal termination; but in syphilitic meningitis the long chronic course leads to such an advanced stage of the resulting lesions that tabes is the inevitable result. The mechanism of its development is exactly the same, he declares, as in meningitis of any other origin, and it is possible that any toxic-infectious process in the meninges, especially if attenuated and chronic, is liable to reproduce, in whole or in part, the anatomic and clinical picture of tabes, if it has time enough.

52. ***Morbid Dread of Blushing.***—Hartenberg has always found an organic basis for excessive blushing, some physiologic peculiarity creating a predisposition to the emotional reflex. In six cases described in detail the following signs were found: the heart was exceptionally active, the beat powerful, but its rhythm was not accelerated; the carotid arteries were engorged and the head sweated easily; drops of moisture appeared on the brow and cheeks as the individual was speaking. Only one of the patients was a woman, the others were men between the ages of 18 and 32. The cardiac erethism, dilatation and hypotension of the arteries suggest certain symptoms of exophthalmic goiter, and one of the patients had other symptoms of an incomplete form of this disease. Hartenberg conquered the habit and morbid dread of blushing by the galvanic current, which he has found useful in exophthalmic goiter. The positive electrode was applied to fit around the front of the neck, the negative on the back, abdomen or elsewhere; a current of 50 milliamperes was applied for thirty minutes every day at first, then every second day. This electric treatment was supplemented by 2 or 3 gm. of bromid daily, with some restriction of salt. Twenty or thirty electric sittings were generally necessary. Psychotherapy does not remove the cause.

54 *Dorsal Percussion of the Heart and Its Application in Interpretation of Grocco's Paravertebral Triangle of Dulness. J. Teissier.

54. **Grocco's Paravertebral Triangle.**—Teissier gives a detailed analysis of the triangular area of dulness close to the spine to which Grocco has called attention as a sign of pleural effusion, and discusses the mechanism responsible for the phenomenon. His conclusions differ from those generally accepted as he ascribes it mostly to dilatation of the right auricle. The resonance of the region involved becomes less when the spine is in contact with a fluid as in pleurisy or with a solid object as in case of encroaching dilatation of the heart or displacement of the mediastinum. Dilatation of the right heart is the most frequent cause, he asserts, and is the main factor in the majority of cases. The sign shows that something is wrong in the cardiopulmonary circulation or that there is inflammation in the subjacent pleura or both. In a case reported in detail, the triangular area of dulness corresponded to the dilated right auricle. The top of the triangle was not quite so high as the surface of the effusion, and it persisted after its subsidence to some extent. Teissier thinks that not enough attention is paid to dorsal percussion of the heart and analysis of the findings.

71 What Paris Does for Children with Bone and Joint Tub culosis. (Die Fürsorge der Stadt Paris für Kinder Knochen- und Gelenktuberkulose.) G. Joachimsthal.

63. **Gastric Ulcer and Pulmonary Tuberculosis.**—Stiller views the various theories in vogue as to the origin of gast ulcer and its frequent coincidence with pulmonary tuberculo and then states his conviction that both can be traced to congenital condition to which he long ago called attention asthenia universalis. This is responsible, he says, for the c ditions which predispose to gastric ulcer on the one hand to pulmonary infection on the other. The form of b peculiar to phthisical subjects, the flat chest, etc., is, reiterates, merely the expression of the asthenia universa and the dyspepsia of the tuberculous is merely the nerv dyspepsia which forms part of the appanage of the univer asthenia. This throws light, Stiller thinks, on Weinber statement that neurasthenia in many cases is a sign of lat tuberculosis; he had noticed that many of his patients who had neurasthenia later became victims of tuberculosis, w the children of tuberculous parents seemed peculiarly prone neurasthenia. The identity of the phthisical and asth- constitutions explains these facts at once. If he had loo about him, Stiller remarks, he would have seen that th are numerous other equivalents of neurasthenia besides tub culosis; dyspepsia, ptosis of various or all the viscera, ato of the stomach, the splashing sound, hyperacidity, etc.— symptoms of the asthenic habitus. Zielinsky found a surpr ingly large number of congenital anomalies in the external internal organs in nearly all of 900 tuberculous cadavers. T asthenia universalis does not necessarily entail tuberculos many healthy individuals are encountered with the narr shoulders, the floating tenth rib, the drooping, exception oblique ribs and the frail skeleton. This demonstrates t this form of body is not the result of existing tuberculosis some have maintained. Stiller adds in conclusion that hygienic-dietetic measures employed in treatment of tub culosis are in reality directed mostly against the underl asthenia.

64. **Prostatectomy in Two Sittings.**—Kayser does not ad cate this as a general rule, but he is convinced that it is p sible to save by two operations, under local anesthesia, a nu ber of patients with prostatic enlargement whom otherwise would be unable to relieve as it would be out of the quest to inflict a single long operation on them, to say nothing of general anesthesia which alone might so easily snuff out spark of life. Most patients with prostatic enlargement are an age when any operation is risky, especially under g or spinal anesthesia. If the bladder can be restored imately to normal conditions by the preliminary oper patient will be much better able to stand the stress operation on the prostate, while the operation in two s materially reduces the danger of infection of the wou another advantage of the two-sitting technic is th ple repose which it imposes on the bladder goes a lo ation ensuring better muscular functioning of that rellary reports the details of four cases in which he Sa tis- principles, with unusually good outco coprole en patients could have survived

80 *The Plague. Trautmann and W. Vierhuff.

73. **Tuberculosis in Children.**—The research reported supplements Gaffky's previously reported research on 300 child cadavers. The present article reports examination of an additional hundred. By inoculation of guinea-pigs with material from the bronchial and mesenteric glands tuberculosis was revealed in 19.5 per cent., that is, in 78 of the total 400 cadavers. In forty-two cases both bronchial and mesenteric glands were affected, in fourteen the mesenteric alone and in twenty-two the bronchial alone. In 98.68 per cent. of the tuberculous cases the tubercle bacilli were apparently exclusively of the human type; an unmistakable bovine type was found only in one cadaver. These findings confirm, Rothe remarks, the preponderant importance of inhalation of the germs for the development of tuberculosis in children.

74. **Local Hyperemia in Pulmonary Tuberculosis.**—THE JOURNAL mentioned Jacoby's announcement in 1897 of the advantages of inducing hyperemia in the lungs by lowering the upper part of the trunk. This "autotransfusion," as he called it, flushes the apices and does away with the mechanical conditions favoring the progress of the tuberculous lesion. He uses a special reclining chair in which the entire trunk lies horizontally, the head can be slightly raised, while the legs lie higher than the shoulders. By this arrangement, the pelvis is on a line with the chest, not lower than the chest according to the usual method of reclining. The pelvis can be raised a little higher than the chest by an interposed cushion which supplements the hyperemia induced by the autotransfusion with compression of the base of the lungs by the pressure of the intestines sliding down against the diaphragm. The respiration is more of the costal type, and the lungs are much better ventilated when the trunk is lying flat than when the patient is half sitting up, possibly with the shoulders stooping for-

ere may not be a primary intestinal form of the plague; in a case at Hamburg plague bacteria were found in the stool for two days. The man recovered. It is important, Trautmann adds, to have trained clinicians, bacteriologists and sanitary officials to handle the plague properly; it may be possible also that meteorologic and geologic factors are involved. He does not think that the statements of the English plague commission in regard to the intermediation of the flea are based on sufficient experience to establish a law; it must be remembered that the conditions were incomparably favorable for positive findings. There is still room for suspicion that some other factors may be involved in transmission of the plague. This is suggested by the experiences at Hamburg: None of the force engaged in exterminating the rats on the vessels from plague-infected ports has ever contracted the disease although many of the Cheopis fleas survived the gases that killed the rats. The men handling them never became infected. The flea theory also seems to be disproved by the "plague houses" in which the plague returns year after year although the inhabitants had fled and the buildings stood vacant for many months. He thinks that the rats surviving the plague would have left the empty house, taking their fleas with them. He has also been impressed by the anatomic differences between the plague rats in India and those arriving at Hamburg.

Vierhuff reviews the reports made by Zabolotny, who has just returned from Manchuria, and Skschiwan of Odessa at the recent public health congress at St. Petersburg. There were 141 cases of plague at Odessa last year; and the cases all occurred in the same blocks and some in the same houses where the last epidemic of plague had occurred in 1902. The bubonic form predominated; generally the glands in the groin were involved, only rarely the axillary glands; only two cases of the pneumonic form were encountered. A local connection with the plague in rats was beyond question, and about 50,000 rats were killed and 60 per cent. examined. The disease is still prevalent in rats there so that the epidemic cannot be regarded as over although no cases have been reported recently. The antiplague measures will have to be kept up for a year at least.

82. **The Local Refrigerating Effect of Ether.**—Postoperative pneumonia has been much reduced in frequency since more care has been taken to prevent chilling the patient's body, but not enough attention has been paid hitherto to the chilling resulting from the local refrigerating effect of the ether inhaled. Joss found that the ether cools the air inhaled through the mask so that it averages 33 degrees F. below the temperature of the room, and the difference may even be 44 degrees during certain phases of the anesthesia. The cooler air chills the air passages, undoubtedly lowering their resisting powers and checking the movements of the cilia of the ciliated epithelium lining them. The ciliary movement is affected by variations in temperature and is entirely arrested at the freezing point. Infectious material is thus liable to find its way more readily into the finer air passages as salivation becomes increased under the influence of the anesthetic. The problem

118. **Gonococcus in the Blood.**—Lofaro found gonococci in the blood in 58.2 per cent. of sixty-seven cases of acute or chronic gonorrheal urethritis; in all the cases of chronic urethritis with stricture; in over 66 per cent. of cases with glandular involvement, in 50 per cent. of the cases of vulvitis and vaginitis, and in over 73 per cent. of the cases of urethritis with epididymitis.

121. **The Wassermann Reaction in Syphilis.**—Gavini has been studying the Wassermann test as applied to 367 syphilitics, seventy suspects and ninety-six healthy persons. The findings show that a negative reaction does not exclude syphilis but that an intense and even a moderate reaction is of extreme diagnostic importance. The subsidence of the reaction under treatment is a reliable index of the efficacy of treatment.

125 *The Diaphragm Reflex. C. Quadrone.

125. **The Diaphragm Reflex.**—Quadrone has been studying the diaphragm reflex in over 2,000 persons and has become convinced that it is a very instructive sign of normal functioning; its absence indicates paresis or paralysis of the diaphragm or neuritis of the phrenic nerve, except in elderly persons and in the very obese, in whom the parts have lost their elasticity or the motor reaction is invisible. The absence of the reflex may throw light, he says, on obscure affections compromising diaphragm functioning, and also on the prognosis in acute infectious disease. The reflex is a physiologic cutaneous reflex, elicited by tickling the tip of the nipple or the areola. This induces a contraction of the diaphragm which is readily perceived as the patient lies on his back, against the light, the head nearly flat, the legs slightly flexed. As the diaphragm contracts the ensiform appendix is drawn inward and sometimes also the inner portion of the costal arch.

129 *Heredity and Degeneracy.* (Kritik av degenerationslæren.) H. Evensen.

127. **Fat Embolism.**—Benestad remarks that no cases of fat embolism are reported except the severe ones with fatal outcome. Most of these cases followed orthopedic operations and fractures. The view is gradually gaining ground, however, that fat embolism is a much more frequent occurrence than formerly was supposed possible. Leading authorities have long insisted on the difficulty of diagnosing it, but in three cases in his practice in the last six months there were puncta-
cutaneous hemorrhages, and he thinks that thisdrome and
reveal the fat embolism in many cases which otfation is the
escape detection. He has been unable to find the necropsy
on record. His patients were workingmen fyfour hours after
old, with fracture of the tibia or femurck under chloroform.
brought almost at once to the hos neck had been removed

lure of the fracture while thacing glands, the patient was in
goupid. The apathy wa fever and sweats, and nothing was
founaccident and keto explain the *fatality* except the fatty
degenounted to the liver, the pale and loose consistency of
the hearstmuscle and the pronounced degeneration of the kidney parenchyma—these findings being a perfect reproduction of those published in the *reports of the twenty-six cases* on record of tardy chloroform *fatalities*. Muskens is convinced that the tardy effects of chloroform intoxication are more serious than has been hitherto recognized by the *profession* and the laity. Two fatalities from this cause have been observed during the last two years in the course of the [illegible]400 chloroform operations at the Rotterdam city hospital[illegible] the chloroform

cough and the others coughed violently, or in the fatal out
predominant symptom. All complained of lausible to try t
more than at the point of the fracture. Thof fat before a
or blowing over the lungs but here and thistering any oil
could be heard over both lungs at the close or elimination
there was some expectoration; the sputum exa medicines
that of pneumonia in one case. The temperatu was
at first, and then kept at a subfebrile height. The diagno
of pneumonia seemed inevitable when the discovery of
petechiæ cleared up the diagnosis. The punctate hem
rhages in the skin were numerous, and they did not subs
under pressure of the finger. They were disseminated sy
metrically over the sides of the neck, over the chest and p
of the abdomen. The petechiæ disappeared after a week.
cough and expectoration gradually subsided, the temperat
returned to normal, and by the end of the second we ki
patient was well and lively. All the patients re
Benestad says that nothing but the assumption of fat em oit
will explain these cases. The fracture was a simple In
all, without dislocation.
